tive lovebirds can be bred on a constant basis, and young birds become sexually mature at about 80 days, around 37 days after fledging. These are adaptations of species that live in unpredictable environments where opportunities for breeding may suddenly arise and must be seized. By and large, however, the proportion of breeding birds in a population of parrots in any one year is low. Thus only a third of the Grey Parrots in Ghana usually participate in the annual nesting cycle. Similar figures are shown even by the small Green-rumped Parrotlet; and in the prolific Monk Parakeet the proportion of adults breeding varied in one study from 37% to 60%. Work in Manu National Park in 1986 concluded that just two out of 20 or more pairs of Blue-and-yellow Macaws observed daily in one area were nesting, suggesting that pairs of this species might breed no more than once every several years. Only one of the two pairs appeared to be successful, so the evidence strongly implies that, even in pristine habitats in areas of Amazonia where annual fruit production is higher than elsewhere, breeding rates of Blue-and-yellow Macaws are exceptionally low. Moreover, year-round censuses of this species, Scarlet and Red-and-green Macaws noted that less than one fifth of all pairs were observed with young at the end of the breeding season. Such evidence has been vital in indicating how serious the removal of breeding-age adults from a macaw population might be.

The frequency of breeding in the Kakapo, and the level of breeding success in the Kaka, are directly related to food abundance. In the Kakapo the deferral of breeding over several years, until a significant masting event provides for the nutritional build-up and weight gain (see Morphological Aspects) of both males and females, is a strategy which minimizes waste of resources in unsuccessful attempts. Similarly, Kakas appear to depend on infrequent seeding of key beech species: in one South Island population, only one successful nest was found and only four of 31 radio-tagged birds attempted to breed within a six-year period, while on Kapiti Island in 1989 the number of active nests was just one third of the number in 1988, and their success was under one third of the success in 1988, with starvation the chief cause of mortality.

Movements

A remarkably small proportion of parrots can be described either as truly "migratory", which implies the seasonal transfer of entire populations from one region to another, or as "sedentary", which implies no movements further than some 50 km from origin. The majority of the family falls into the ill-defined area of migrations that are partial, dispersive, nomadic, irruptive, irregular and local. This condition is the result of the complex and sometimes unpredictable spatial and temporal patterns of fruiting and seeding in the wet and dry tropical and subtropical zones to which most parrots are confined. Moreover, most descriptions of psittacid displacements are deliberately vague and tentative because knowledge of this aspect of their life histories is as nugatory as it is difficult to acquire; one of the difficulties in teasing out information about movements from poorly studied birds is that many parrot species, including the Red-fronted Parrot (*Poicephalus gularis*) and Blue-crowned Parakeet (*Aratinga acuticaudata*) as notable examples, having been seen in the non-breeding period in noisy flocks, become exceptionally quiet and unobtrusive when breeding, such that they might be assumed to have left the area.

Full, seasonally driven migration, as classically understood, is only known to occur with certainty in two species, the Swift Parrot and the Orange-bellied Parrot, both of which breed in Tasmania and move the relatively short distance across the Bass Straits to spend the austral winter in south-east Australia. A third species, the Blue-winged Parrot, does the same thing, but in this case there is an apparently resident south-east Australian population over which the Tasmanian migrants are believed to leap-frog.

Complete sedentariness is slightly commoner, if only because a number of species are confined to islands too small to permit any wide-ranging movements. Most Pacific and Indian Ocean species, including the Neotropical Socorro Parakeet (*Aratinga brevipes*) and the various parrots of New Zealand and adjacent

The rosellas are a closely related group of Australian parrots, commonly called broad-tails or flat-tails, a direct translation of the generic *Platycercus*. The Northern Rosella lives in savanna woodland, coastal forests, occasionally mangroves, and trees growing along watercourses. It is mainly seen in pairs and small groups foraging for seeds on the ground. As breeding draws near, pairs begin to indulge in courtship feeding and display. The male squares his shoulders, ruffles up breast and tail coverts, wagging his fanned tail and chattering all the while. The nest-site is in the limb or trunk of a tree, typically a eucalypt standing near water. The clutch consists of 2-4 eggs, which the female alone incubates, leaving the nest briefly to forage for herself or to be fed by the male. Upon hatching, for the first few days the nestlings are tended by the female and then by both parents. The young birds become independent about a month after fledging, but they may remain with their parents until the following breeding season.

[*Platycercus venustus*, Katherine Gorge National Park, Northern Territory, Australia.

waters, are sedentary, although at least one *Vini*, the Blue-crowned Lorikeet (*Vini australis*), and one *Cyanoramphus*, the Red-fronted Parakeet, sometimes move between islands. Philippine parrots, whether nectarivorous or granivorous, all appear to be largely resident, although some vertical displacements may occur in higher-altitude species. Virtually no other Asian or Australasian species can be said to be sedentary, with the notable exception of the rosellas, where ringing has shown birds to be strongly and continuously tied to the natal area. In one study, as many as 598 out of 2288 ringed Eastern Rosellas were controlled or recovered, and of these only one, marked as a juvenile, was found away from the ringing site: this bird was just 3 km away. Similarly, 146 recoveries of 1741 Crimson Rosellas yielded just six found away from the ringing site, the farthest one, again marked as a juvenile, being 20 km distant.

In Africa several *Poicephalus* parrots appear to be sedentary, although careful study might reveal a different picture; among lovebirds only the Grey-headed of Madagascar appears likely to qualify. In the Neotropics, Indigo and Red-fronted Macaws, confined to very circumscribed areas, appear always to meet their needs within them, and the same is true of the Blue-throated Parakeet, Yellow-faced Parrotlet (*Forpus xanthops*), Blue-bellied Parrot (despite earlier reports of movements into coastal areas) and possibly Spix's Macaw (*Cyanopsitta spixii*). The various parrots of the Caribbean islands are also largely sedentary, but some distinct seasonal shifts in numbers and presence are or once were recorded. Young Monk Parakeets do not disperse far, with average distance from natal to nesting site being only 1.2 km in one study.

Altitudinal displacements occur in many Andean species, including two amazons, both *Enicognathus*, both *Psilopsiagon*, three *Touit* and four *Pyrhura*; the only comparable movement to have been documented outside the Neotropics is undertaken by the Slaty-headed Parakeet of the Himalayan foothills, although the Australian King-parrot and the Ceylon Hanging-parrot show some vertical shifts in numbers with season, and Ground Parrots in Tasmania's uplands are as-

sumed to come lower in winter, since their breeding habitat gets blanketed in snow.

All elevation changes can be viewed as local seasonal movements that are simply easier to detect, in part because (presumably) entire populations are involved. Many other species are known or believed to perform seasonal migrations that are local in nature – meaning, here, undertaken in part but not all of the species's range and/or involving only a partial evacuation of areas, both of which make the determination of pattern all the more difficult. Examples include the occupation of Kangaroo Island, off South Australia, by the Elegant Parrot (*Neophema elegans*) in its presumed breeding period (November–April) only, and the Rock Parrot's presence on the same island apparently only after breeding (January–May); the Derbyan Parakeet's summer visitor status in north-east India; the Grey Parrot's dry-season wash into Ghana's evergreen forest for breeding; the Brown-necked Parrot's annual appearance on Zimbabwe's central plateau; the post-breeding displacements of the Red-spectacled Amazon (*Amazona pretrei*) north and east of its breeding areas; and the complex seasonal wanderings of the Great Green Macaw (*Ara ambigu*) in the Caribbean lowland and slope forests of Costa Rica. One of the most interesting, because apparently so local a phenomenon, is the mid-year invasion of Surinam's coastal sand-ridge forests by many Amazonian species, squeezed out of their normal habitat by food shortages at the end of the rainy season.

Many of the remaining species in which movements are known will doubtless prove to have more structured patterns of displacement than is covered by the term nomadism. Apparent wandering behaviour may prove to be long-distance coverage of a large home range; both the Cyclopsittini and Micropsittini may exhibit such patterns if they are not, in fact, sedentary. Nevertheless, opportunist response to food availability remains a clear life history strategy in some parrots, notably those whose specialization on one food exposes them to danger from periodic mass crop failure, such as the *Rhynchopsitta* parrots and Golden-

Some parrots are known for the peculiar habit of nesting in termitaria. Strangely, the termites do not seem to attack the birds and probably seal off the nesting area. Some species of Aratinga parakeet habitually nest in arboreal mounds: using only their bills, they dig a tunnel upwards into the mound at first, then, turning downwards for some distance, they finally hollow out a large nesting area. The case of the Peach-fronted Parakeet is not clear, as its breeding habits are practically unknown. One pair was seen leaving a hole in an arboreal termitarium, which tempts one to suggest that this individual may actually have been nesting inside, but the photographer was sadly unable to check.

[*Aratinga aurea*, Serra da Canastra National Park, Minas Gerais, Brazil. Photo: Luiz Claudio Marigo]

In its homelands of north-eastern Australia, the Golden-shouldered Parrot is so well known for its habit of nesting in termite mounds that it is often referred to as the "Antbed Parrot". The terrestrial mounds that it uses are of two types. It prefers spectacular, conically shaped mounds to lower, flatter ones, and the former may reach a height of over 2 m. Helped by the softening effects of the rains, the parrots endeavour, sometimes unsuccessfully, to dig out a long tunnel in the crumbling earth. This terminates in a spacious nesting chamber, where the clutch of 3-6 eggs is laid. Happily, there is compensation for these labours, in which both sexes participate. Since the temperature within the mound remains relatively high, the chamber acts rather like an incubator. Consequently the eggs or young chicks can be left unattended for hours at a time, leaving the female free to forage for herself, though she may still be fed by her mate. Incubation lasts about 20 days, and both parents attend the young, which leave the nest some five weeks after hatching, though they remain with their parents to form family parties.

These Eclectus Parrots survey the scene from their nest-hole, alert to the possible presence of other claimants to the site. Characteristically, they choose to nest in a tall tree in a clearing or on the forest fringe. The hollow can be up to 600 cm deep and is invariably high, with one found 58 m up a giant fig tree. The clutch of two eggs is laid on a lining of wood chips. Reports of groups of up to 7-8 birds seen in attendance at nest-sites lead to the suggestion that birds from previous broods may help in the raising of the young. This species is remarkable for its extreme dichromatism, so much so that the sexes were long considered to be distinct species.

plumed Parakeet (*Leptosittaca branickii*), for example (see Status and Conservation). Elsewhere in the Neotropics, many macaws, amazons, *Aratinga* parakeets and *Pionus* parrots appear to wander after breeding in unpredictable directions, and a few species, notably the Yellow-faced Amazon (*Amazona xanthops*) and Scarlet-shouldered Parrotlet (*Touit huetii*), seem sometimes as unpredictable in their breeding as in their non-breeding distributions. In Asia and Papuasia perhaps only two species, the Blue-rumped Parrot of the Greater Sundas and the Blue-collared Parrot (*Geoffroyus simplex*) of New Guinea, may match the pattern where breeding areas are as movable as non-breeding ones, but the nectar-dependent Loriinae and *Loriculus* remain too little known to exclude them from this category. However, plant phenology on the islands from Wallacea east to the Solomons is almost certainly so continuously staggered through the year that nectar-feeders probably only rarely encounter spatial bottlenecks that render large areas uninhabitable for more than a few weeks. Nevertheless the substantial daily flights so commonly reported, and so utterly uncomprehended, in lorries and lorikeets indicate that birds are under constant pressure to keep pace with the ever-changing conditions of their feeding environment.

Some species, including three out of six *Eos*, at least three other lorries, the Great-billed Parrot (*Tanygnathus megalorynchos*) and Blue-topped Hanging-parrot (*Loriculus galgulus*), exhibit their post-breeding nomadism as island-hopping. However, this remains a very poorly documented phenomenon; the distances they traverse over water, and with what regularity, are unknown. Indeed, one of the intriguing questions is the age-structure in wandering flocks. In two well studied species, the Kea and Eastern Rosella, these flocks are composed of younger birds yet to establish themselves within the optimal habitat occupied by the adults. Many records of nomadic behaviour in parrots, including perhaps island-hopping, and also the phenomenon of wandering by otherwise sedentary species such as rosellas and lovebirds on the fringe of their ranges, may primarily refer to dispersive or displaced immatures.

One of the key causative factors in parrot movements is water. In arid and semi-arid environments on all continents the shifting availability of water sources explains many observed inter-forest and other displacements. The nomadism of some species of parrot in the dry interior of Australia is certainly related to rainfall distribution, green growth and drinking water. However, while harsh conditions require some species to be essentially nomadic, a few are better characterized as irruptive. These include the Princess Parrot, which appears to have a core population around Lake Tobin but which, after several favourable years, builds up its numbers to irrupt opportunistically into many other parts of the interior; and the Scarlet-chested Parrot and, less certainly, the mysterious Night Parrot, neither of which is yet known to have a single core area into which it retreats in times of climatic harshness, but both of which have provided evidence that several such areas may exist.

Relationship with Man

Man has a pronounced love/hate relationship with parrots, although the people who love them and those who hate them are not the same. Parrots are loved, of course, for their companionship, personalities, colours, and, in particular, ability to talk; they are hated for their adverse impact on human food production. Between these two extremes they are for trappers, seeking to supply the demand either for living pets or for much-prized feathers, simply a commodity to be utilized with dispassionate resolve.

The value attached to parrots as talking companions is reflected in the very derivation of the name, corrupted from the French *Perrot* or *Pierrot*, diminutive of *Pierre*. European explorers, wherever they went in the tropics, almost invariably encountered local tribes that had tamed some form of parrot, and experience quickly showed that no other kind of bird could more easily be kept alive on board ship and brought home as living testimony of the voyage; and the novelty of an animal that talked

Posing exquisitely outside a large tree hollow, these Hyacinth Macaws display all the beauty of their shape and colour. The largest and arguably the most spectacular of all the parrot species, the plumage is a deep rich blue overall, relieved only by the naked yellow eye-ring and bare skin at the base of the lower mandible. This pair was observed to carry out an inspection of the cavity, presumably with a view to subsequent occupation. Depending on availability, these macaws use hollows in tall trees, especially in the trunks of palms. They are also recorded as nesting in cliff holes that present the advantage of being more difficult of access to ground predators. Only two, very occasionally three eggs are laid, the female being entirely responsible for their incubation. The nestling period is a protracted 3-4 months, a length normal in the larger parrots, but it is rare for more than one youngster to be successfully reared.

A male Budgerigar feeds its mate at the nest-hole. In this species cere colour identifies the sex, since it is blue in the male and brownish in the breeding female. Nesting is often communal and may take place in any month of the year after good rains have fallen. There may even be two breeding seasons if circumstances permit. Budgerigars, perhaps the world's best known parrots, owe their name to the aboriginal word "betcherrygah", roughly translatable as "good food", and their initial popularity to John Gould, the famous nineteenth century bird illustrator, who introduced these birds into Europe, describing them aptly as "the most animated, cheerful little creatures you can possibly imagine."

[*Melopsittacus undulatus*, Pink Lakes National Park, Victoria, Australia. Photo: David Watts]

could not be underestimated. Indeed, the first parrot known to be mentioned in any human writing, a century before Aristotle, was a Plum-headed Parakeet (*Psittacula cyanocephala*) that could speak an "Indian" language.

The fascination exerted over man by parrots had an early manifestation in the annals of the Roman Empire, when individual favourites were kept in tortoiseshell and ivory cages with silver wires, while their less fortunate relatives were prepared as delicacies for luxurious banquets; one emperor is even said to have fed them to his lions. In the two thousand years since then parrots have remained by far the most familiar and popular of avian pets. There can, of course, be no question that they provide large numbers of people with the innocent pleasure of company and care. The therapeutic value of pets to man is now known to be high, and it is probably highest in those animals, dogs and parrots in particular, with which people feel most able to communicate verbally. Parrots themselves often bond strongly with their owners, and it appears that they in turn derive comfort and interest from these relationships. It is a bitter paradox, however, that, although they may no longer directly supply the extravagances of emperors, they certainly continue to suffer the incidental and largely unheeded consequences of human possessiveness and wonder: the path from forest to front porch is littered with the corpses of the less fortunate, and is darkened by an untold history of suffering that no animal-lover would normally countenance or accept responsibility for.

To date, however, the only major international legislation enacted in relation to trade has been for taxic rather than individual protection. This is CITES, the Washington Convention on International Trade in Endangered Species, to which 134 countries were party at the end of 1996. CITES identifies those species for which trade has potential negative effects: on Appendix I of the convention go those forms whose conservation status is so adverse that any trade is deemed unacceptable; on Appendix II go those forms whose conservation status is such that trade might pose a threat

unless properly regulated by permits. Ever since 1981 all Psittaciformes, with the exception of the Rose-ringed Parakeet, Budgerigar and Cockatiel, plus of course those on Appendix I, have been listed on Appendix II. The main reason for such blanket listing is that many of the rarer parrots resemble some of the commoner ones, and could easily escape correct identification at national frontiers.

In theory, then, CITES provides a substantial filter on parrot trade around the world. In practice, some parties have not met their obligation to introduce domestic legislation adequate to fulfil their requirements under the convention, and in any case a great deal of smuggling takes place. In this latter regard the most notorious of all parrot victims must be Spix's Macaw, which has been on CITES Appendix I ever since its creation; private ownership of this macaw was even prohibited under Brazilian law in the 1960's. The species was not rediscovered in the wild, other than by trappers, until 1985, by which time all but five birds had been spirited into the hands of some of the world's richest collectors; four of the remaining wild birds went the same way within three years. No amount of legislation on its own was adequate to help so coveted a species. In some ways even more alarming was the way in which the listing on Appendix I of the Hyacinth Macaw actually increased its international trade, apparently as collectors only then realized its rarity and consequently began offering inflated prices for specimens: once again, practice held sway over principle.

Singapore has the shameful distinction of being the entrepot for an enormous volume of illegally exported birds, including the rarer Neotropical species. The state authorities allow wildlife traders to operate with impunity, and the business has brought enormous wealth to a few dealers, who appear to be able to acquire any parrot they want other than ones from Australia and New Zealand. For example, the Red-and-blue Lory (*Eos histrio*) from the islands north of Sulawesi, Indonesia, is currently being "vacuumed" out of existence by a demand led covertly from Singapore.

Undoubtedly the best known psittacid victim of trade is the African Grey Parrot, which is listed on CITES Appendix II. As a "talker" the African Grey has no equal, and birds from the western end of the range of the nominate subspecies, in Ghana, are judged to be the most intelligent and trainable. The species also represents good value for trapping effort compared to other forms of wildlife: handling is not dangerous, mortality is lower than in passerines, and profit margins are good. Ghana has therefore long been one of the major exploiters and exporters of the Grey Parrot. This is pre-eminently the type of species CITES is intended to help, by ensuring that trading nations acknowledge scientifically determined limits on the number of birds taken each year from the wild; yet until very recently no quantitative assessments of its status had ever been undertaken in Ghana or anywhere else, so that the fundamental premise of the species's ability to sustain utilization was based on nothing more solid than assumption.

In the past the birds were used for food, company, magic and income but, although trappers will still eat birds they cannot sell, there is little place now in Ghana for parrots as food or pets. Their use in magic is also greatly diminished, but the demand for body parts, and in particular the red tail feathers, is strong in Togo, Benin and Nigeria, mainly as a supposed aphrodisiac. The tail feathers can, of course, be plucked from the bird without killing it, so this demand has mainly been met by the wild bird

trade. However, plucking causes great distress to the birds, and infections and mortality commonly result. Unfortunately, banning this practice would probably fuel much illicit hunting, since the consumers have no interest in whether the birds yield their feathers alive or dead.

Three types of trapping are used in Ghana, chief among them being luring. A fairly low tree is selected within a kilometre of a roost, a hide built in the crown, and sticks coated with a preparation of *Landolphia* vine latex placed in the canopy. Several captive birds amongst the limed sticks act as visual lures, while a bird specially trained to give distress calls is kept to hand by the concealed trapper. When a flock of wild birds flies over, the trained bird is squeezed and gives its calls: the wild birds circle in curiosity, and some invariably land near the visual lures and become stuck. These are mainly young, naive birds, so the most productive time for the trapper is in the post-fledging period from March to around July, with success tailing off dramatically by November.

Two other methods are simply to lime the customary "staging tree" in which many birds settle before descending to roost, and to take birds, including the roosting adults, from nests. The former has the advantage of use at any time of year, but is very disruptive to roosts; the latter results in birds in good condition, but only has a very limited period of application. Neither method has anything to commend it in terms of sustainability. Luring is

Despite their gregarious nature, comparatively few parrots breed colonially.

One of these, the Burrowing Parakeet, tunnels into sandstone or limestone cliffs to make its nest-hole, frequently at a considerable height above the ground, overlooking a river or at times the sea.

The burrows, often intersecting to form an intricate network of passages, may be as much as 3 m in depth, ending in a nesting chamber. As they approach their cliff holes, sometimes in groups, these parakeets show masterful split-second timing, gliding in at speed and only folding their wings at the very last critical moment.

Formerly widespread and common in Chile and Argentina, they have been the victims of much ruthless persecution and in parts of their range have been reduced to a few isolated colonies.

[*Cyanoliseus patagonus patagonus*, Chubut, Argentina.
Photo: Günter Ziesler]

thus by far the best practice in management terms, by taking such a high proportion of young birds (80-97% of totals caught), some of which might be likely to die of natural causes in their first year anyway. These young birds also make the best pets and are much more amenable to captive life. However, luring is little different in terms of distress to the captured birds. Traditionally each limed bird was placed in its own sack while the collection was proceeding, but to save time the modern treatment is to clip its wings and throw it out of the tree, with sometimes immediate and sometimes long-term consequences: wing-clipped survivors of the fall are far less efficient at feeding themselves. Once gathered together the birds have their tail-feathers plucked, for the reasons explained above, and are usually crammed into cages that allow them no space to care for themselves.

Mortality between capture and in-country quarantine is claimed to be as low as 3% in Grey Parrots, but this needs independent assessment. In Fischer's Lovebirds trappers claim 5-10% for the same phase, although this can be much higher depending on the experience of the trapper and the distance to be travelled; since lovebirds need water every day, a two-day journey on top of a bus with water that has slopped and spilt in the first hour will kill the entire consignment. In Mexico, 55% of parrots trapped for trade are estimated to die before their first sale. Whatever the case with the African Grey, another 5-10% die in a month-long quarantine, double this amount if the stay is two months. Mortality on the export flight is generally 2-3%. Then there follows a second period of quarantine, in the importing country. Here figures vary, but up to 28% has been recorded. Cumulatively a minimum of 15-50% of Grey Parrots may die between capture and final destination. For Fischer's Lovebirds the equivalent figures are 18-44%.

As the death toll mounts, so too does the price of the individual parrot. In the early 1990's a trapper could sell a Grey Parrot for the rough equivalent of US\$5, the middleman for \$20, the exporter for \$70, and the importing retailer for almost \$500. Precisely the same inflation attends the Blue-fronted Amazon (*Amazona aestiva*), sold for \$4 each by the *campesino* to the "collector", for \$8 by the collector to the exporter, and eventually retailing for \$400 in Europe and the USA. Such trade is clearly extremely lucrative for all concerned: some Ghanaian exporters bought flats in London on the proceeds of Grey Parrot exports, and such is the potential for making money in this business, despite the ban in place since 1986, that many traders have attempted smuggling via Ivory Coast or Togo, often only to incur financial losses from the transport costs, bribes needed, and defaulting payments. Trappers living near the border can more easily trade their birds, however, and the combined effect of this is that some 80% of all Grey Parrots exported from Ivory Coast are actually trapped in Ghana.

Clearly, then, parrots are good business. Throughout the world, the net CITES-reported international trade in psittaciforms, 1982-1988, was an average 539,701 birds per year; these are minimum figures, as some CITES parties failed to report trade statistics, other countries are not parties to CITES, and the level of smuggled parrots is known to be high but remains unquantified. It has been estimated that trappers in Neotropical countries earned US\$33,000,000 gross in the period 1982-1986, with middlemen earning \$114,000,000 gross, while the gross retail value in importing countries reached \$1,600,000,000. The human dimension is illustrated by Guyana, where almost all of the avian exports are parrots: in 1991 a total of 16 exporters provided employment for 430 people, with some 7540 trappers and traders also involved; factoring in spouses, children and associates, about 54,000 people, some 5% of the country's population including the majority of the Guyanese Amerindians, would then have been deriving financial benefit from the psittacid trade. The total declared value of birds exported to the USA from Guyana in 1986 was US\$1,400,000, accounting for 0.6% of all Guyanese exports in that year.

Three closely related issues emerge from these figures. First, there ought to be considerable economic incentive to ensure that the trade is sustainable, so that people may continue to benefit from it. Second, there is an unjust disparity in the value of the parrots at capture and the prices exacted for them from their fi-

nal owners. Third, there is a burning question whether such economic and human benefits should outweigh either the welfare and freedom of the birds themselves or the conservation interests of the species from which they derive.

Australia's long-standing ban on the export of all its wildlife has been held up as a model of conservation and indeed welfare legislation, defining the situation in the clearest and simplest manner. However, for less developed countries, and for those with long land frontiers, the total ban solution is far less easy to implement. Mexico prohibited all native wildlife exports in 1982, but this had no practical effect whatsoever: estimates of the number of parrots smuggled into the USA later in the decade varied from 25,000 to 150,000 annually. Moreover, the blanket ban appears to be a major disincentive to habitat and site conservation for, if no economic value can be attached to the retention of parrot-productive areas, the economic benefits of their conversion inevitably come into consideration. In such circumstances, the right of developing countries to utilize surpluses in their wildlife populations, as a legitimate means of generating income and employment, is difficult for the developed world to deny. Certainly if bans simply drive trade underground and/or result in the destruction of the habitat of the birds in question, which is effectively to condemn them to death by starvation, little is gained either for their conservation or for their welfare.

As a consequence, it has been argued that the solution lies in fuller management and stronger assertion of CITES principles. It is clearly in the interests of suppliers and conservationists alike to ensure that the traffic in parrots is sustainable, and if the trappers could achieve a better share of the profits then the treatment of the parrots themselves might improve to the point where welfare outrage would acquiesce. A welfare-sensitive sustainable harvest regime requires a comprehensive management framework involving such things as scientifically determined capture and export quotas, greatly improved trapping and export procedures, agreed systems of pricing, foreign exchange generation, profit-sharing with local communities, and full, independent monitoring of populations, habitats and all trade practices. This, at any rate, is the ideal. In addition, it has been suggested that various management interventions could greatly improve the yield, such as adding nest-boxes to increase nest-site availability, predator-proofing existing nest-sites, providing supplementary food, and "pulling" first clutches so as to encourage multiple clutching, the aim being to boost the number of nestling parrots, which make the best pets, so as to harvest the surplus without in any way affecting existing population levels. There is much difference of opinion over whether a moratorium on parrot trade, while the potential for sustainable harvesting is being investigated, would be effective or counterproductive in terms of its impact on parrot populations.

The cardinal issue is co-operation between parties on an agreed and equitable basis. In Argentina, the exploitation of the Blue-fronted Amazon is so riven with rivalry for the short-term profit that nest-trees are readily cut down to obtain nestlings, and indeed entire *campesino* families deploy themselves to guard nests day and night as "harvest" time approaches. As many as 100,000 nest-trees were either destroyed or irreparably damaged for nesting purposes in the period 1981-1989, and the taking of every nestling even from trees left standing has led researchers to predict a major population crash in Argentina in the 1990's. Already it was noted that an area that produced 3000 nestlings in 1986 yielded only 500 in 1991, and falling numbers have now resulted in a new illegal trade in the species out of Paraguay. In such a vicious circle everyone ultimately loses, and most of all the parrots: a rationalized system of ranching may offer the only hope.

It may also offer the only hope against the control of unscrupulous smuggling. In the period 1975-1984 trappers virtually eliminated the large macaws from a California-sized area of forest in lowland Bolivia, the spokesperson for the middlemen boasting of exporting around 500 birds a fortnight, a putative total of 130,000 birds. Bird-fanciers with inside knowledge of illegal trade reported a minimum 10,000 Hyacinth Macaws taken from the wild in the 1980's, with one astonishing but presumably ex-

This historic photo is the first ever taken of an adult Orange-bellied Parrot with chicks. This Endangered species, with an estimated population in the wild of fewer than 200 birds, now breeds only in south-west Tasmania, migrating in winter to the Australian mainland. The nesting hole is usually up to 25 m from the ground in a living eucalypt; 3-6 eggs are laid. While the female Orange-bellied Parrot incubates she is fed by the male. Parrot chicks are highly altricial; most hatch without down and require constant brooding, but within two weeks the female Orange-bellied Parrot begins to share feeding duties with her partner. As the chicks grow, the feeding, by regurgitation, may take place as often as three times an hour. Despite the asynchronous egg-laying of parrots, these chicks appear to show surprisingly little difference in size and are already quite well feathered. After fledging, the juveniles of this species often form groups of up to 15 individuals and remain together, even though their parents may already have departed on their migration to the mainland.

[*Neophema chrysogaster*,

The Princess Parrot was named after royalty in a fashion current in the mid-nineteenth century, when many species were being discovered. A highly enigmatic parrot, found only in the interior of western and central Australia, its appearances are so sporadic and unexpected that its status is largely unknown. Probably an opportunistic breeder, it may nest at any time of year after good rainfall. The nest-hole is usually in a eucalypt near water, and several pairs may nest in a small colony, with as many as ten pairs found in the one tree. After fledging, both parents and young depart from the breeding area almost immediately. Note the spatule visible on the end of the wing, a peculiarity of this species.

aggregated claim of up to 300 a month for three years. CITES returns do not, of course, disclose any of this despoilment, and in the absence of the political will to beef up patrolling and enforcement there seems no alternative but to provide an incentive for the more honest among the trappers to become policemen on their own as well as the parrots' behalf.

None of this, of course, relates to the problem of internal trade. In certain countries, notably Brazil and Indonesia, domestic demand for parrots is very high but virtually uncharted. In these and their adjacent countries the use of parrots, and especially their feathers, by native tribes is another important dimension. Macaw flight feathers are much used in Amerindian head-dresses. Pesquet's Parrot plumes have major value in many New Guinea societies in relation to bride purchase. Skins of Black-capped Lorries (*Lorius lory*) are often worn by the natives of the middle Sepik River as dance ornaments. In the southern Cook Islands in ancient times the small red feathers of the Rimatara Lorikeet (*Vini kuhlii*) were much prized for the adornment of people, god images, caps and elaborate ceremonial head-dresses. Overexploitation of these small parakeets seems to account for their loss from the southern Cooks, and indeed there is good evidence that many long-distance inter-island voyages by Polynesians were spurred by the desire to obtain lorikeet feathers. Clearly, they often took a number of birds with them, which led to various species becoming established on islands outside their natural ranges. Thus on Aitutaki, in the southern Cooks, the loss of the Rimatara Lorikeet made it possible for Blue Lorikeets to establish themselves when brought there some time before the start of the twentieth century.

Often, however, introductions of parrots are regarded with concern, because of their potential to inflict economic damage on foods during cultivation. Of the 353 psittaciform species no fewer than 54 (15%) appear to be considered as crop pests in some degree or in some contexts. Almost inevitably the two worst offenders within their natural ranges, South America's Monk Parakeet and the Afro-Asian Rose-ringed Parakeet, are also the two best colonizers of man-modified habitats outside those

ranges, and both are greatly feared in consequence. Neither is able to withstand cold winters, however, so it is in the southern parts of the USA and in the Mediterranean basin that their populations are most likely to find a firm grasp. As an example of the damage Rose-ringed Parakeets can do to orchard crops like citrus, almonds, *Cordia*, papaya and dates, in one calculation where the estimated loss of citrus was 8.6% of a total of 864,300 t, the loss to India in foreign trade earnings in 1986 was calculated at Rs 146,000,000, or about US\$11,000,000. Compounding this is the fact that the skin ruptures produced by parakeet attack expose crops to infestation by fruit-flies, which can then totally ruin what the birds began.

Prognostications are not always on target. There were expectations that Grey Parrots, for which oil-palms are a natural food, might become a serious pest in oil-palm plantations. However, it turned out that the plants are so productive that only a tiny fraction of their daily output could ever be eaten by the parrots, whose numbers have not so far increased in response to the suddenly much increased quantities of the food, probably because of the limitation on reproductive output represented by the number of nest-sites. In Western Australia, too, the large cockatoos cause far greater losses than smaller birds such as Red-capped Parrots, Western Rosellas and Port Lincoln Ringnecks (*Barnardius zonarius*): in any one season during the period 1973-1975, no single orchard suffered losses greater than 1.4% of the total fruits grown. Moreover, researchers have found a solution to the problem in growing foods that decoy birds away from commercially valuable plants. In the case of the Regent Parrot (*Polytelis anthopeplus*), for example, it has been proposed that sudan grass (*Sorghum sudanense*) can be planted both as a wind-break and as a decoy, since it supplies a preferred food source right through the period of orchard fruiting. In Argentina, the relatively negligible damage done by Blue-fronted Amazons to citrus orchards, which is used as an excuse for trapping birds, could be prevented through improvements in agronomic practices, patrolling, and bird-scaring devices. Possibly the same could be done with the hapless Burrowing Parakeet, which with its

Screeching flocks of Austral Parakeets seem strangely out of place as they fly around in the temperate beech (*Nothofagus*) and oak forests of southernmost Chile and Argentina.

In the northerly part of their range they are found up to 2000 m, coming lower in the winter, but further south they are resident all the year, despite the severe climatic conditions. The favourite nest-sites are tree hollows or abandoned woodpecker holes in large dead oaks.

Remarkably for parrots, Austral Parakeets prepare a deep hole by filling it with specially broken twigs and a layer of dry leaves and feathers on top. If no suitable hole is available, they are reported to build their own nest of dry twigs and grass stems in the dense tangles of *Chusquea quila* bamboo. Apart from the fact that the clutch consists of 4-6 eggs, little is known about their breeding behaviour in the wild. The two nestlings peering out of the narrow nest entrance appear as small replicas of the perched adult bird, complete with brownish forehead patch and dark edges to the feathers.

Scarlet Macaws offer a brilliant splash of colour, as they glide over the Amazon rain forest in Brazil. Certain macaws, including the Scarlet, are known to move seasonally in search of fruiting trees, but no clear pattern is discernible, except that in summer they habitually penetrate into semi-arid forest in Colombia. Large numbers of Scarlet Macaws used to visit Pacific tropical forest and swamp regions in Mexico, but all those birds have long since disappeared, emphasizing the dismal decline in numbers of this spectacular species.

[*Ara macao macao*, Mamiraua Sustained Development Reserve, Amazonas, Brazil. Photo: Luiz Claudio Marigo]

innocent adoption of cereal grains in what were once its empty grassland habitats has prompted unsavoury retaliation in the form of dynamiting of whole colonies and mass poisoning of feeding flocks.

Status and Conservation

Based on the most recent (1994) assessment of globally threatened parrots by BirdLife International, 86 (26%) of the 332 psittacids in the world are at risk of extinction, with a further 36 "near-threatened"; indeed, if one includes the 21 cockatoos within the Psittacidae, this means adding seven threatened species and four more "near-threatened". It is a proportion unmatched by any other large family of birds, and testifies to the peculiar vulnerability of parrots both in environmental terms and as an economic resource, for it is the combination of habitat destruction and trapping for trade that is responsible for this exceptionally high rate of threatened members of the family.

There is, however, a third element involved, namely range size. In an analysis of avian species with ranges of less than 50,000 km², aimed at identifying critically important centres of biological endemism ("Endemic Bird Areas" or EBA's), BirdLife established that no fewer than 63 (68%) of the 93 threatened psittaciforms are restricted-range species, and that as many as 127 (36%) of all parrots and cockatoos have this characteristic. The ratio of threatened to non-threatened restricted-range species (1:1) shows the relevance and value of range size in judging the conservation status of taxa; but the sheer number of restricted-range parrots itself also reveals the success of the family in colonizing virtually all tropical wooded habitats on all continents and the great majority of islands.

However, the susceptibility of the family is further, and perhaps even more poignantly, illustrated by the 18 parrot taxa listed in 1981 as having become extinct between 1600 and 1980, a figure only then matched by the rails, notorious for their defencelessness against rats and cats on oceanic islands (see Volume 3, page 138). In addition, the documents of early travellers and settlers have revealed that many more species of parrot, notably in the West Indies, existed at the time of the European voyages of discovery than the physical record shows. The West

Indies appear to have been particularly rich in macaws: among those with the most convincing written evidence of their existence are *Ara erythrocephala* and *A. gossei* from Jamaica, *A. atwoodi* from Dominica, *A. martinica* from Martinique, *A. guadeloupensis* from Guadeloupe and *A. erythrura* from an unknown island. Other accounts refer to amazons and parakeets without further specification, on islands where none exists today. In some cases the birds involved may have been escapes brought in from the American mainland; but overall it is clear that a substantial proportion of the parrot fauna of the West Indies was lost in the four centuries following their discovery, and small testimony to this are the 15 or so specimens of *Ara tricolor* from Cuba and the single bone of *A. autochtones* from St Croix.

These extinctions are not easily traceable to cause, since they occurred so long ago, but we can infer some explanations by reference to conservation biology in general and parrot, notably macaw, biology in particular. To begin with, island birds of any family are commonly less well adapted to cope with mammalian predation pressures than continental forms, since they evolved in the absence of such pressures: when animals such as rats enter their environment for the first time the birds do not recognize them as dangerous and have no behavioural mechanisms to prevent the loss of themselves or more often their nests. Perhaps of greater import, the survival prospects of any relatively large frugivore on any relatively small island will be seriously prejudiced by the loss of a part of its habitat, and, as the remaining area diminishes, the chances increase that a fruiting failure will leave the birds nothing to eat for a long enough period that they starve: this is, of course, one of the reasons why any species with a circumscribed range is likely to be more susceptible to extinction than one that extends more widely. Finally, the written record tells us again and again that the human colonists of the Antilles sought out the larger parrots for food: indeed, such direct persecution of island birds has been a common cause of their extinction around the planet: there is, for example, a woodcut dating from 1602 showing men catching large parrots on Mauritius, doubtless the macaw-sized, weak-flying *Lophopsittacus mauritianus*, which died out probably around 1680, while the existence of three *Vini* parrots (two of them totally extinct) on the Marquesan island of Ua Huka has only been determined from

Spix's Macaw teeters on the very brink of extinction in the wild; these two historic photos taken in 1990 tell of its tragic fate. The first shows the one known survivor when it was located by members of a Brazilian team of scientists, and was seen repeatedly perched in a caraiba tree. The second shows the bird in the same tree, this time in the company of a Blue-winged Macaw. This strangely assorted pair were observed together over a five-day period and from the posturing behaviour of the Spix's Macaw it was thought to be a male. Subsequent tests carried out on its feathers in 1995 confirmed this, and a captive, wild-caught female was released back into the wild to join it. Unfortunately, the pair did not form a bond, most probably because of the strong relationship the male had already established with the Blue-winged Macaw. After some time the released bird disappeared. Recent reports confirm that the male Spix's Macaw is still alive and paired with the Blue-winged female. Indubitably, unscrupulous trapping and trafficking in the species led to the ultimate denouement, but the underlying cause of its decline has been the gradual and now almost total elimination of the caraiba woodland on which it relies to provide suitable roosting and nesting sites.

the middens of the earliest Polynesian settlement dating to 1500-2000 years ago.

The importance of the island factor, involving range restriction and biological defence reduction, can be gauged from the fact that 16 of the 18 forms listed as extinct in 1981 were from islands. There are, however, two notable parrot extinctions from continents, the first of which is absolutely certain, the second virtually so: the Carolina Parakeet in North America, and the Glaucous Macaw (*Anodorhynchus glaucus*) in South America. The Carolina Parakeet occupied a huge range from the eastern seaboard south from Virginia and west as far as a line from Nebraska to Texas. Within this area it lived in heavily forested river valleys, the same habitat as its equally famous partner in death, the Ivory-billed Woodpecker (*Campephilus principalis*). Because the woodpecker lasted far longer, habitat loss could not have been the sole cause of the parakeet's demise; but because the parakeet's decline was steady and not sudden, disease has been ruled out as well. The species was not a specialist feeder, like the nomadic Passenger Pigeon (*Ectopistes migratorius*), perhaps the most famous of all North American losses, although it would readily switch from its abundant weed and tree seed diet to cultivated fruit. It appears, therefore, that it was straightforward human persecution, partly in reprisal for its orchard raiding, partly for the cagebird trade, that caused its demise, but the evidence is by no means conclusive.

The Glaucous Macaw was far less well known, but because of its very close relation to Indigo Macaw the reasons for its disappearance are more confidently discernible. Glaucous Macaws actually vanished so early that naturalists in Europe in the early 1800's only knew them from live imports brought in by traders with no knowledge of their precise origins. The few details of their history and distribution have had to be compiled from reports of travellers who were not sure what they were seeing, naturalists who happen to mention blue-green macaws with yellow faces glimpsed in the course of voyages up rivers or through swamps; it is still possible that one day some old forgotten chronicles of early life in southern Brazil, Paraguay or northern Argentina will reveal more information about these

mysterious birds. However, because the bills of the Indigo and the Glaucous are the same size, and the Indigo appears to have evolved to crack the nuts of licuri palms (*Syagrus coronata*), Glaucous Macaws are assumed to have tackled similar-sized nuts: and the palm that produces the closest match to licuri within the lost bird's range is the yatay (*Butia yatay*), which experienced devastating levels of clearance in the last century as the River Paraguay basin was settled by cattle ranchers. It appears that the collapse of this food resource, doubtless coupled with hunting, sealed the fate of this magnificent parrot, unless in some remote tract of an Argentine *estero* a small population has somehow managed to survive.

One parrot killed off by persecution compounded by habitat loss, the other by habitat loss compounded by persecution, and neither of them with small ranges: the lesson is there for the learning. Again and again these two factors have combined to bring the members of the family into the danger zone: their joint effects are felt by 38 (45%) of the 84 threatened parrots and cockatoos. As in the case of the Glaucous Macaw, habitat loss can mean simply loss of food resource, and obviously it can also simply mean loss of living space; but very often, and perhaps most crucially but least understood, it can mean loss of breeding space, a factor of particular though not peculiar importance to parrots. Persecution likewise takes several forms: birds may be taken for their feathers, or as a good meal, and the two are not mutually exclusive; or for the pet trade (see Relationship with Man).

Total loss of habitat is inevitably a disaster for any organism, and its effects are obvious and predictable to its human witnesses. Deletion from the habitat of a key element on which the organism depends, on which it is in some way specialized, is far less easy to detect until the organism itself shows a response. We are still some distance from understanding the particular vulnerabilities of parrots through their specializations, and for this reason the total number of threatened species may be an underestimate; nevertheless, it is certainly the case that parrots, by virtue of dietary adaptations and breeding requirements, do represent a group within which there is a high degree of specialization, and their overall status is therefore very likely to deteriorate faster than many other groups. The facts that trade is barely monitored at all if it is internal (national), and that it can shift very quickly from one species to another depending on fashion and developing national infrastructures, are further reasons for concern that the total number of threatened species in the family is underestimated. On the other hand, a common though not universal trait is the underestimation of bird population sizes, and there is a growing body of evidence that parrot numbers are very often badly misjudged, so that some species may have been mistakenly listed as at risk. Altogether, then, the assessment of threat status in the family is a difficult and unrewarding endeavour.

Elimination of food resources is blamed for the presumed extinction of Australia's Paradise Parrot (*Psephotus pulcherrimus*): the burning of seeding grass to create green growth for cattle was probably critical among several adverse changes to its environment. Its close relative the Golden-shouldered Parrot is in retreat for the same reasons. In Colombia the near-total clearance of stands of wax palms (*Ceroxylon quindiuense*), ironically the country's national tree, has caused the disappearance of the Yellow-eared Parrot, which not only fed on their fruit but bred in holes in their trunks. What are almost certainly this bird's closest relatives, the Thick-billed and Maroon-fronted Parrots, are similarly specialized on the cones of the many different pines that grow on the Sierra Madre Occidental and Oriental in Mexico. Like the Yellow-eared Parrot, the Thick-bill also depends on its food-trees for nest-sites; the Maroon-front has made itself a little more secure by nesting in cliffs.

The two Mexican parrots are peculiarly vulnerable because their food resource is patchy in both space and time. We now know that the extinction of the Passenger Pigeon, once arguably the most numerous bird in North America, was caused not so much by hunting as by habitat loss (see page 109). The species used to wander over vast areas, in search of patches of masting forest, and would breed opportunistically when it found

The Black-cheeked Lovebird is restricted to a very small area of Zambia, where it now occurs in much reduced numbers. A lowland species, closely associated with mopane woodland, it suffered heavily from trapping in the 1920's. A subsidiary cause of its decline may have been the elimination in the 1950's of the sorghum and millet on which it was a crop pest. Numbers are now thought to be in the nature of 10,000 individuals and the species is currently regarded as Endangered.

[*Agapornis nigrigenis*.
Photo: Dennis Avon/
Ardea]

them. In a scaled-up version of the problem already mentioned (the effect of habitat loss on large frugivores on small islands), the loss of increasing areas of forest made the search for masting areas energetically more expensive and a positive outcome ever less certain; and when there was a simultaneous masting failure in the remaining forest patches, the last of the birds simply starved.

The two Mexican parrots, although rather more seasonally tied, clearly fit the pattern: in a sense they function as gigantic crossbills (*Loxia*), well known for their irruptive behaviour when pine-seed crops fail in the usual parts of their ranges. It was doubtless such a failure that led to the Thick-bill invasions of and temporary residence in southern Arizona around the turn of the century, which have been interpreted as evidence of a former permanent presence in the USA. Now that old-growth pine forest in both sectors of the Sierra Madre has suffered massive clearance, large numbers of Thick-bills are a thing of folklore, and the species is pegged back in the core of its range, further limited by loss of large dead snags in which to nest. Because of their partial nomadism, meaning that they cannot be expected to remain long-term in any one place, it is not inconceivable that a simultaneous pine-seed crop failure could happen and the species disappear without anyone recognizing the fact for several years.

Another parrot which may fit this pattern is the Golden-plumed Parakeet of the Andes, the treatment of which as a threatened species has sometimes been queried. If, however, its nomadic behaviour is related to a particular, though not exclusive, dependence on the cones of *Podocarpus* trees, then again it may be that a temporal bottleneck in food availability could eliminate the species before anyone even notices.

The extent to which this problem afflicts parrots is not known, and it is certainly the case that most parrots seem to be able to switch diets in times of food stress, although whether they obtain sufficient nutrition from foods to which they are less adapted is a matter of conjecture. It is also the case that some birds thought to be relatively strict food specialists, such as Red-spectacled and Vinaceous Amazons (*Amazona vinacea*) on the cones of *Araucaria angustifolia* and the Blue-bellied Parrot on the hearts of the palm *Euterpe edulis*, have proved to be far more generalist than expected; Blue-bellies in fact ignore *Euterpe*! Then again it may prove that there is an important but limited seasonal dependence on a particular food, so that its unavailability through habitat loss can be just as devastating as if the dependence was almost total; and there may yet be cases where almost total dependence exists but has not yet been recognized.

All this uncertainty is a warning to conservationists to exercise the precautionary principle. Unfortunately this must in some cases mean arguing for the retention of habitat for some species in the expectation that the birds might only come to use it once in 20 years. We clearly need to know a great deal more about the food habits of parrots and the fruiting phenology and life cycles of their food plants before being able to make anything more than vague guesses at what the resources are that each species needs to ensure its survival on the planet.

Elimination of nest-sites is, meanwhile, another form of habitat loss which can compromise a parrot's prospects, all the more insidious for often being rather difficult to detect. In Australia the age of *Eucalyptus* trees used by several species of psittacid is surprisingly old at over 500 years, and there is a dawning perception that modern timber-harvesting practices have already compromised the long-term reproductive ability of these species by removing trees in age-classes that are needed now or in the next few hundred years to provide safe homes (see page 267). A similar problem faces Brown-necked Parrots, which use dead *Podocarpus* trees; if regeneration of these plants continues to be prevented by trampling or cutting, the long-term prospects for the species are extremely poor. On Sumba in Indonesia it was recently found that the native parrots nest in the oldest, largest trees available, and that the number of individual parrots in a forest patch was directly correlated with the number of nest-sites it contained.

In the New World the whole question of nest-site availability as a limiting factor in parrot populations is also now recognized as highly relevant. Even the pest-status Monk Parakeet is inhibited from invading converted *pampas* until man-planted eucalypts reach a certain size or until pylons and other tall structures are erected within the open landscape. At the other end of the scale, the best explanation for the confined range of Spix's Macaw is that its reproductive capacity depended on the presence of mature caraiba trees (*Tabebuia caraiba*). These trees formerly stood in large stands along the margins of the River São Francisco and its minor tributaries, but long-term European settlement of the region, coupled with the fact that caraibas grew in places most favoured for maize cultivation and where pasture lasts longest in the dry season, led to their wholesale clearance. Nowadays, just a few creeks retain just a few kilometres of extremely narrow gallery woodland with just a few trees of sufficient age to be of value to the macaw; indeed this may have been the case ever since Spix made his greatest ornithological discovery in April 1819.

In the Pantanal, Hyacinth Macaws are under considerable pressure from lack of nest-sites, as nest-trees have commonly been cleared for the sake of cattle, sometimes because their cavities also play host to vampire bats but for the most part simply in order to open up more ground for pasture. Inevitably a hole-nester will require a large hole and, almost inevitably, a large hole is an adjunct of a large, and therefore old, tree. Hyacinth Macaws, the largest of all the parrots, although capable of nesting in cliffs, clearly cannot survive in open, cliffless landscapes from which the old trees have been eliminated. Very recently one pair has taken to breeding in a nest-box erected in an area where there was a perceived shortage of breeding sites; this is a very welcome development, because to date the common experience with nest-boxes has been that parrots larger than a *Forpus* do not much like them.

Among the first people to discover this aversion were those working to save the amazon parrots of the Antilles, in particular the St Lucia Amazon (*Amazona versicolor*) and Puerto Rican Amazon. Although the great majority of parrots can be induced

By the 1970's the total population of the St Lucia Amazon was estimated to amount to only 100-150 birds: habitat destruction, hunting and hurricane damage had all taken their toll. Measures were then initiated to encourage local awareness and pride in the parrot. It was declared the National Bird, a forest sanctuary was designated to protect the remaining breeding pairs, and guided walks organized to promote interest among natives and tourists alike. The species has benefited so much from all these efforts that the population has now risen to around 300-350 birds.

The New Zealand flightless Kakapo, the heaviest and most curious of all the parrots, has long been the hapless victim of man. Exploited first as an abundant source of food, it then fell easy prey to the animal predators introduced in the nineteenth century. Now extinct throughout its natural range, it survives precariously on three tiny offshore islands, having been translocated there by the New Zealand Wildlife Service within the last decade. The Kakapo's complicated lek mating system and complete lack of breeding activities some years offer no hope for a rapid increase in numbers. By 1997 the total population was still only 50 birds. The one encouraging sign is the hatching of four chicks in early 1997, the first breeding success recorded since 1993.

[*Strigops habroptilus*, Maud Island, New Zealand. Photo: Gérald Cubitt/WWF/Bios]

to breed in captivity using artificial boxes prepared by the breeder, nest-boxes set out in the wild have held no attraction, even when all wild alternatives appear to have been taken. In frustration at the indifference of the Puerto Rican birds to their boxes, the recovery team elected instead to enhance existing potential nest-sites within the species's last forest site, Luquillo, scooping holes to greater depths, drilling drainage channels, using chicken wire to fit false bottoms, and visoring entrances with zinc sheeting, and after 1976 all sites used were ones that had been improved by human intervention. That nest-site availability was a real constraint was finally proven after the devastation of Hurricane Hugo in September 1989: what was certainly a catastrophe at one level for the species, with 47 birds before the strike being reduced to 21 after it, proved ultimately to have been a blessing for, by destroying so much it caused the forest to react by fruiting more, in a competition to fill the gaps, and by tearing off so many limbs from the larger trees, it created a new generation of natural nest-cavities in the forest. Breeding success in the 1990's has consequently been encouraging, and the species has started to recover its numbers.

It is the conservation effort on behalf of the Puerto Rican Amazon that has taught the world the most about the management of small parrot populations and the nature of the problems such populations face. To begin with, of course, it was habitat destruction that reduced the population to low numbers

and ultimately to a single location. Hunting and pet-taking had concurrent effects but, by the time the small area of remaining habitat had been secured in the late 1960's, these factors began to amplify the danger. The colonization of Puerto Rico by the Pearly-eyed Thrasher (*Margarops fuscatus*), doubtless in part facilitated by the forest clearance that had already disadvantaged the parrot, brought a new problem: these birds, themselves constrained by suitable breeding sites, attack eggs and young of parrots in nest-cavities. At the time thrasher numbers were building up in Luquillo, so were those of the parasitic bot- or warble-fly *Philornis pici*, almost certainly because it favours thrashers as hosts: inevitably, however, other hole-nesting species suffered from this shift, and none more so than the parrot, with 25% of its young experiencing infestation in the period 1973–1979. As if this was not enough, introduced honeybees (*Apis mellifera*) had by then become common in Luquillo, and in the same time-frame took over at least five parrot nests in the post-breeding period; at various stages, too, local people cut trees with bee nests in them to get at the honey, once again making the parrot the greatest loser. It was once feared that black rats (*Rattus rattus*) were a major nest predator and, although there is no proof of this, prophylactic action is constantly taken to reduce their possible impact on the parrots. Indeed, it is worth noting that nest watches over a 17-year period, 1973–1989, resulted in at least 20 nests fledging young where,

without human intervention, they would have failed. Escaped monkeys may fairly easily reach and colonize the forest, bringing further risks not only of nest predation but food competition. Other species of parrot are free on Puerto Rico and likewise represent a potential threat in terms of nest and food competition and through the transmission of disease.

Stochastic events assume great potential and significance when a population descends below a certain level. For the Puerto Rican Amazon the danger from hurricanes is particularly serious, and although all Caribbean parrots must very largely be "hurricane-adapted", as exemplified by one Imperial Amazon (*Amazona imperialis*) that survived 13 days without food before fully recovering, and although in 1989 it turned out that Hugo also had a beneficial effect, as outlined above, once a species is tightly confined to an area it is totally at the mercy of chance events. On Puerto Rico, hurricanes are blamed for the annihilation of the Culebra subspecies *gracilipes* in 1899 and the Río Abajo population of the nominate form in 1928. In 1967 a major drought coincided with the period of maximum rate of decline of the species. The collapse of nest-trees during breeding attempts has occurred twice since 1954, and predation by Red-tailed Hawks (*Buteo jamaicensis*) can be significant, at least on subadults, for at least two out of five radio-tracked birds were killed by hawks at 4 and 163 days after fledging; it would take one wintering Peregrine keying in on Amazon foraging flights for the entire population to disappear in a season.

It is these kinds of event that seem likely to lie behind apparent fluctuations in numbers of *Vini* lorikeets on their often tiny islands. Time and again one encounters contradictory reports of the rarity or abundance of a species on an island visited at different times by observers. For example, in 1984 some 200 Blue Lorikeets were estimated present on Aitutaki, in 1991 under 1000, and in 1994 about 1200, and while some of this may be attributable to chance and observer competence, there is no reason why populations should not fluctuate with conditions: apart from droughts and cyclones, phenomena like good and

bad flowering years may have profound effects on population levels. Clearly in such highly constrained circumstances, when a population is on a naturally induced downward trend, it only takes one small man-related development to make that trend irreversible.

Another example of a parrot in an extinction vortex is the Mauritius Parakeet. On Reunion its close relative *Psittacula eques*, almost certainly conspecific, disappeared probably as the result of intense long-term hunting pressure. On Mauritius the main problem was habitat loss, compounded initially by hunting but long outlasting this factor: the World Bank's funding for clearance of upland dwarf forest on Plaine Champagne in 1971–1974 caused the already tiny population of 58 to plummet to below 10 by 1980. Meanwhile, nest predation by the area's 4000-odd introduced crab-eating macaques (*Macaca fascicularis*) was blamed for depressed breeding success, as was nest-site competition from introduced Rose-ringed Parakeets and Common Mynas (*Acridotheres tristis*). Later the monkeys were absolved of nest predation but implicated in food competition, along with black rats. Once again severe weather is believed to have played a part, with one major cyclone in 1975 halving the number of nest-trees, and one in 1979 apparently reducing the number of birds. Food shortages at the end of winter, owing not merely to the season but to the degraded state of natural forest on Mauritius and competition from other sources, were feared to be causing a temporal bottleneck through which only the fittest birds could pass. Moreover, the cyclones themselves strip food from trees, and with no forest left elsewhere the option to forage in other parts of the island as in former times no longer exists; and of course wind damage to forest opens it up for the invasive plants and animals that can more quickly degrade it and outcompete its native fauna.

The same kind of story emerges from New Zealand, where the Kaka is fighting a rearguard action against exotic invaders. Here, more detailed scientific study has uncovered a depressingly intractable problem. Kakas greatly exploit honeydew, a

From the almost total lack of information concerning both its feeding habits and breeding behaviour, the Red-browed Amazon appears to have attracted scant attention from scientists and observers alike. An inhabitant of humid lowland forests in coastal areas of Brazil, it has suffered from the massive deforestation carried out there in recent years and has vanished completely from some parts of its former range. Distribution is now very local, and the species is still subject to trapping. Though present in various reserves and national parks, its continuing survival is far from secure and it is currently listed as an Endangered species.

high-energy food, in summer and autumn, and it appears that they depend on it to bring them into breeding condition the following spring. Outcompetition for this resource by introduced and plainly uncontrollable wasps and possums appears to be directly related to the Kaka's critically low reproductive output; hence a crash in the parrot's numbers can be safely predicted in the next few decades.

In due course the Kaka may become as challenging and problematic for conservation as its near namesake, the Kakapo. This flightless nocturnal lekking wonder, the heaviest of all parrots, evolved like the Dodo (*Raphus cucullatus*) in the absence of mammalian predators, including man. Once, however, stoats (*Mustela ermina*), black rats and cats had escaped into its range on the main islands of New Zealand its fate there was sealed. Eventually, the only option biologists could take was to translocate birds to offshore islands free of these predators. However, if defencelessness against mammalian predators was one result of long isolation and probably of intraspecific competition, extreme K-selection in the form of life so long that reproductive efforts may be deferred for years, was another. Just as the Kaka needs its honeydew, the Kakapo needs a major masting event of podocarps in order to trigger breeding activity. By providing supplementary food biologists have to some extent overcome this problem, but with the added complication of the lekking system, the existence at one stage of only two females (it is typical of lekking species that there should be a high male:female ratio), and a naturally low output even in optimal conditions, the opportunities to increase the species's numbers have been very limited.

Exotic invaders can even include conspecifics. On the island of Sangihe north of Sulawesi, the nominate race *histrion* of the Red-and-blue Lory has been reduced by trade to perhaps 30 birds, but so many birds of the race *talautensis* have now passed through the island that several have escaped and appear to be commingling with the nominate form. On Cebu in 1996 there was an attempt, fortunately thwarted, to intro-

duce another race of the Philippine Hanging-parrot by people unaware that the highly distinctive indigenous form *chrysonotus* had just been confirmed as surviving in the island's last forest patch. At its most extreme the problem may not even be exotic or invasive: the very last wild Spix's Macaw, a male, formed an attachment with a Blue-winged Macaw, and when a female Spix's was released its prior attachment clearly prejudiced the situation, and before a decision on the appropriate management could be taken the released bird disappeared, taking with her, perhaps, the last real chance for this exceptionally beautiful animal.

However, Spix's Macaw breeds in captivity, and there is now a consortium of holders, run by the Brazilian conservation authority IBAMA, that is attempting to maximize the reproductive output of the 30–40 individuals they manage. Regrettably, most of these birds are related to each other, and the majority may be the offspring of one pair, so problems of inbreeding may be encountered in due course. Of greater ultimate significance, however, is whether captive breeding can really further the interests of species that rely so heavily on learning and handed-down tradition in relation to their environment. Macaws take years to discover the secrets of their environment, and it seems improbable that captive-bred individuals of a species extinct in the wild could easily, and in some cases ever, pick up the information they need from scratch. At any rate, when wild-caught Thick-billed Parrots (which are modified macaws), including one bird that had lived 30 years behind the bars of its cage, were turned loose in southern Arizona, they all immediately knew what to do, how to handle food, how to respond to each others' signals, how to avoid predators; but when expensively captive-bred birds of the same species were liberated into the same area, they failed to recognize food, or alarm calls, or predators, and within days they were all either dead or back in their cages.

For certain species, such as Tasmania's Orange-bellied Parrot, captive breeding may yet prove valuable, particularly those

The Indigo Macaw takes its scientific name from Edward Lear, better known for his nonsense rhymes than for his life's work, painting birds. Long known only from traded birds, it remained a mystery until it was rediscovered in Brazil in 1978. It now survives only in a small area of caatinga vegetation dotted with stands of licuri palms, on which it relies for nuts. Even though the species may never have been very widespread, the gradual clearance of these palms over recent years has drastically reduced its range. The limited amount of suitable habitat and continued illegal trapping compromise the survival of this very striking bird.

[*Anodorhynchus leari*,
Raso da Catarina, Bahia,
Brazil.

All but two of the hanging-parrots are confined to island territories of greatly varying sizes. The Sula Hanging-parrot inhabits only the Sula and Banggai Islands, very small archipelagos in the western Moluccas. Within these islands it appears to be quite common, so it must continue to find sufficient primary and secondary forest where it can still feed and breed satisfactorily. In the absence of any evidence of hunting or trapping of the species, it appears to be an example of a parrot which can continue to live successfully within a very confined area, provided it and its habitat are left in peace.

[*Loriculus sclateri*, Taliabu, Sula Islands, Indonesia.

with less specialist needs which can be raised by their parents, socialized in an aviary without inappropriate imprinting, and let loose amidst wild birds. Even so, there remains the spectre of disease transmission from caged to wild birds, since the former are likely to have been in touch with any number of other species, and parrots are notorious bearers of infection (psittacosis, a viral disease that can be transmitted to humans, was originally found to afflict parrots, although it is now known to affect several other bird groups too). There also remains the question of whether the causes of original loss from the area have been adequately addressed: often enough, captive breeding is embarked on without consideration of this vital issue. Altogether, therefore, captive breeding is not a management technique to pursue unless circumstances present no choice.

Translocation, such as has been practised with the Kakapo and some of the *Vini* lorikeets of the Pacific, has the virtue of relative simplicity, cutting out the middle stage of captive breeding, although in fact the Kakapo is also being husbanded in zoos; it is used basically to lift populations out of the path of exotic predators. It might just be applied in continental situations where exploitation had caused local extinction, but the homing instincts of many species may then be counterproductive. Apart from this, the constraint on the technique is clearly that there must be somewhere secure to which birds can be taken without prejudice to existing wildlife, and outside of fairly depauperate islands the opportunities for this are small.

The lesson of all these extreme cases is the importance of not allowing cases to become extreme: the best way to look after a species is to give it enough space and strength to look after itself. This inevitably means attempting to ensure that there is sufficient habitat, both for breeding and for feeding, sufficient control of exploitation, in terms of hunting as well as trade, and sufficient protection from exotic predators and competitors to ensure that each species remains in balance with its environment. BirdLife's development of the concept of the EBA, explained above, of which there are over 220 on the planet, was in one respect an attempt simply to determine the prime geographical targets for cases not yet extreme but likely to become so in the fairly near future. With 36% of all parrot species confined to EBA's and many others (the precise number is not known) occurring within them, the importance of establishing large, secure

protected areas in representative parts of these centres of endemism is obvious.

However, security depends on local and national goodwill, and in hard-pressed economies this is only likely to be achieved through the kind of pride-building awareness campaigns spearheaded by P. J. Butler in the Caribbean, and through the inclusion of parrot-watching activities in the general packages of attractions offered to internal and international tourists, both of whom represent important sources of income. Countries that happen to possess macaws and clay-licks are at a particular advantage here, but parrots are wonderful advertisements for wilderness and diversity wherever they occur, and are among the most easily marketable of animals in the service of nature conservation. In this regard they probably have a stronger role to play than any other bird family: the sooner they get to play it the better.

Subfamily LORIINAE

Genus *CHALCOPSITTA* Bonaparte, 1850

1. Black Lory

Chalcopsitta atra

French: Lori noir **German:** Schwarzlori **Spanish:** Lori Negro
Other common names: Rajah Lory

Taxonomy. *Psittacus ater* Scopoli, 1786. New Guinea.

Forms a superspecies with *C. duivenbodei*. Occasionally included in *C. scintillata*. Race *insignis* may be an incipient species. Possible race *spectabilis* known by the type from Mamberik Peninsula, NW New Guinea; this form is close to race *insignis* but may be a hybrid with *C. scintillata*. Three subspecies currently recognized.

Subspecies and Distribution.

C. a. bernsteini Rosenberg, 1861 - Misool I.

C. a. atra (Scopoli, 1786) - Batanta I, Salawati I and W Vogelkop (Irian Jaya).

C. a. insignis Oustalet, 1878 - E Vogelkop, Amberpon I and Onin and Bomberai Peninsulas, Irian Jaya.

Descriptive notes. 32 cm; 260 g. Glossy purplish black, with bare orbital skin and skin at base of bill black; rump blackish blue; underside of tail olive yellow, basally red. Immature has bare skin on face whitish. Race *bernsteini* has reddish purple markings on forehead and thighs, paler rump; *insignis* has forehead, area around bill, leading edge of wings, underwing-coverts and thighs red; head streaked grey-blue, rump dull blue.

Habitat. Open habitats including coastal plantations, grassy savanna and forest edge; also mangroves, *Nypa* palm forest, freshwater swamp and dryland forest; even very open,

stunted forest on limestone.

Food and Feeding. Seen feeding at flowering *Schefflera* shrubs.

Breeding. Male in breeding condition in Dec. In captivity: 2 eggs; incubation lasting c. 25 days; nestling period c. 75 days.

Movements. No information, but occurrence in large flocks and use of open habitats, which may exhibit pronounced seasonal regimes, suggest some local displacements may occur.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Locally common, often in large flocks, but a better understanding of each race's populations needed. International trade was moderately high in late 1980's, with 2808 exported in the four years 1987-1990; commercial importation into the EC from Indonesia was banned in Sept 1991.

Bibliography. Andrew (1992), Anon. (1993), Beehler *et al.* (1986), Harrison & Holyoak (1970), Lint (1969), Low (1978, 1993c), Rand & Gilliard (1967), Ripley (1964), Sayers (1974a, 1974b), Sujatnika *et al.* (1995), Sweeney (1997c).

2. Brown Lory

Chalcopsitta duivenbodei

French: Lori de Duyvenbode **German:** Braunlori **Spanish:** Lori Pardo
Other common names: Duyvenbode's Lory

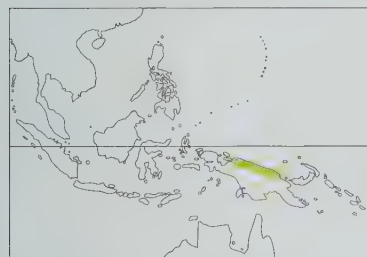

Taxonomy. *Chalcopsittacus Duivenbodei* Dubois, 1884. New Guinea = Tana Mera.

Forms a superspecies with *C. atra*. Two subspecies recognized.

Subspecies and Distribution.

C. d. duivenbodei (Dubois, 1884) - NW New Guinea E into W Papua New Guinea.

C. d. syringanuchalis (Neumann, 1915) - NE New Guinea.

Descriptive notes. 31 cm. Generally warm mid-brown; bill, skin around bill, and bare orbital ring black; forehead and feathers around bill yellow, shading to mid-brown, with narrow yellow streaks on sides of neck and nape; breast faintly scalloped yellow; bend of wing yellow; underwing-coverts and thighs orange-yellow; rump violet; outer tail feathers with some yellow; legs dark grey. Female usually lacks yellow in tail. Immature duller, with less yellow. Race *syringanuchalis* darker on head and back.

Habitat. Primary lowland and tall secondary forest, up to 200 m; sometimes seen along for-

est edge.

Food and Feeding. No information available.

Breeding. Apr. In captivity: 2 eggs; incubation lasted 24 days; nestling period around 11 weeks.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Apparently irregular in numbers, common in some places and rare in others within range.

Bibliography. Andrew (1992), Auber (1934), Beehler *et al.* (1986), Berggy (1978), Coates (1985), Courtney (1997b), Dolton (1991), Greensmith (1975), Low (1984), Pearson (1975b), Rand (1942b), Rand & Gilliard (1967), Ripley (1964), Robiller & Trogisch (1983b), Sujatnika *et al.* (1995).

3. Yellow-streaked Lory

Chalcopsitta scintillata

French: Lori flamméché **German:** Schimmerlori **Spanish:** Lori Chispeado

Taxonomy. *Psittacus sintillatus* [sic] Temminck, 1835. Lobo Bay, New Guinea. Species name emended to *scintillatus* in 1839. Three subspecies recognized.

Subspecies and Distribution.

C. s. rubrifrons G. R. Gray, 1858 - Aru Is.

C. s. scintillata (Temminck, 1835) - S New Guinea from Triton Bay (Irian Jaya) E to R Fly.

C. s. chloroptera (Salvadori, 1876) - R Fly E to SE Papua New Guinea.

Descriptive notes. 31 cm; 180-245 g. Generally green; bill, skin at base of bill and bare orbital skin black; lores, forehead to mid-crown red, bordered blackish in indistinct patch from base of lower mandible through ear-coverts to hindcrown, shading in turn to green streaking; irregular red spots and patches on throat and breast; yellow or orange streaks on mantle, breast and belly; thighs red; underwing-coverts red; yellow band across underside of flight-feathers; underside of tail light greenish brown, basally red; legs dark grey. Immature has reduced red on head. Race *chloroptera* has mostly green underwing-coverts; *rubrifrons* has wider, more orange streaking on breast.

Habitat. Lowland savanna and forest, disturbed lower montane forest, secondary growth, sago swamps and mangroves, and coconut plantations, up to 800 m.

Food and Feeding. Nectar or pollen of *Syzygium* (without damaging flowers), nectar of *Brassia actinophylla*, sago palms and *Schefflera*.

Breeding. Apr and Sept; well-grown fledglings in Feb; male with partly developed gonads in Jul. Nest recorded in hollow 24 m up in tree.

Movements. No information, but given occupation of savanna, and occurrence in flocks, there may be some seasonal movements; certainly local abundance seems to be influenced by periodic blooming of certain trees.

Status and Conservation. Not globally threatened. CITES II. Common, often in flocks of up to 30; at one site in SE New Guinea density estimated at 20 birds/km².

Bibliography. Andrew (1992), Beehler *et al.* (1986), Bell (1982), Burrows (1993), Coates (1985), Courtney (1997b), Diamond (1972a), Gregory (1995a, 1995b), Harrison & Holyoak (1970), Hicks (1992), Kyme (1979), Mackay (1970, 1971), Mayr & Rand (1937), Mees (1982a), Rand (1942a), Rand & Gilliard (1967), Tubb (1945).

4. Cardinal Lory

Chalcopsitta cardinalis

French: Lori cardinal **German:** Kardinallori **Spanish:** Lori Cardenal

Taxonomy. *Lorius cardinalis* G. R. Gray, 1849. Solomon Islands. Monotypic.

Distribution. Islands E of New Ireland S through Solomons.

Descriptive notes. 30-31 cm; 173-215 g. Bright red, darker on back and wings; bill reddish orange, dark at base; bare orbital skin dark; underparts lightly edged yellowish, giving vaguely scalloped appearance; legs grey. Immature paler on back and wings, bill dull orange.

Habitat. Mangroves, lowland forest, secondary growth, coconut groves, wherever trees are flowering, lowlands to 1200 m (830 m on Bougainville).

Food and Feeding. Blossoms of *Cocos nucifera* in gardens and of *Elaeocarpus* and *Syzygium* in primary forest, seemingly preferring food trees with red flowers; also small berries.

Breeding. Copulation in Aug. and display in Sept. Only nest reported, Aug, was in hollow, metre-long, near-vertical branch stump near base of 10 m high ridgetop tree, in primary forest at 1150 m, on Kolombangara.

Movements. Birds readily move between islands to feed and roost.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Abundant on Kolombangara, Ghizo, New Georgia, Guadalcanal, Isabel, Bougainville; commonest in coconut plantations and other lowland disturbed sites, less so in lowland and hill forest.

Bibliography. Blaber (1990), Buckell (1996a), Buckingham *et al.* (1995), Cain & Galbraith (1956), Coates (1985), Diamond (1975a), Greensmith (1975), Hadden (1981), Mayr (1945b), Schodde (1977), Sibley (1951), Sweeney (1994c), Virtue (1947), Webb (1992, 1997).

Genus *EOS* Wagler, 1832

5. Red-and-blue Lory

Eos histrio

French: Lori arlequin **German:** Harlekinlori **Spanish:** Lori de las Sangihe
Other common names: Blue-tailed Lory

Taxonomy. *Psittacus histrio* P. L. S. Müller, 1776, Sangihe Islands.
All six *Eos* species comprise a superspecies. Three subspecies recognized.

Subspecies and Distribution.

E. h. challengerii Salvadori, 1891 - Miangas I, N of Sulawesi.
E. h. talautensis A. B. Meyer & Wigglesworth, 1894 - Talaud Is.
E. h. histrio (P. L. S. Müller, 1776) - Sangihe I, Siau I and Ruang I.

Descriptive notes. 31 cm. Red, with orange bill and purplish blue patch on mid- to hindcrown and broad line from around eye down side of neck to mantle; breastband, mantle and back purplish blue; scapulars, flight-feathers and thighs black; wing-coverts tipped black; tail reddish purple above; legs grey. Immature has more blue on crown. Race *talautensis* has less black on wing-coverts and flight-feathers; *challengerii* smaller, with narrower breastband, while line from eye does not meet mantle.

Habitat. Forest and edge, visiting coconut plantations and other open areas to feed.

Food and Feeding. Seen feeding in coconut, *Ficus* and *Canarium* trees.

Breeding. Main period, Talaud, Apr-May, but also Nov-Dec; latter is reportedly main period on Sangihe. Nest in hole in large tree (once a *Canarium*) in both forest and cultivated areas. Eggs usually 2.

Movements. Local people report an influx of up to 150 birds each year on Salebabu, Nov-Mar.

Status and Conservation. ENDANGERED. CITES I (since Feb 1995). A BirdLife "restricted-range" species. Last century uncommon and mainly in hills, Sangihe, but common near the coast on Talaud (presumably the main island, Karakelong); in 1978 the status on both islands was much the same; total population of Talaud was thought to be c. 2000 birds in early 1990's, but survey work in 1995 suggested higher numbers. Owing to extensive habitat loss and trade exploitation, the Sangihe population may be only 30-100 birds, amongst which escapes of the Talaud race now mix; the tiny, deforested Siau and Ruang cannot now hold viable populations. Of the three Talaud islands, the species is extinct on Kabaruang, small numbers survive on Salebabu, while on Karakelong it is still common in the N (communal roost of 400 observed, and another of 500 reported), less so in the S. However, intensive trapping, no longer possible in Sangihe, continues on Karakelong, with as many as 700 birds being taken in 1992/93, and 390-440 in 1994; the majority of these birds appear to have been smuggled to Singapore. Nothing is known of the status of the race *challengerii*, but the population cannot be large and may even be extinct.

Bibliography. Andrew (1992), Barnicoat (1995b), Barnicoat & Laubscher (1995), Bishop (1992), Coates & Bishop (1997), Collar & Andrew (1988), Collar *et al.* (1994), Holmes (1995b), Nash (1993), van Oosten & Riley (1996), Riley (1995, 1996, 1997), Sujatnika & Jepson (1995), Sujatnika *et al.* (1995), Sweeney (1993a, 1995d, 1995g), Wheatley (1996), White & Bruce (1986).

6. Violet-necked Lory

Eos squamata

French: Lori écaillé

German: Kapuzenlory

Spanish: Lori Escamoso

Other common names: Moluccan Red Lory(!)

Taxonomy. *Psittacus Squamatus* Boddaert, 1783, Gebe.

All six *Eos* species comprise a superspecies. Proposed race *atrocaerulea* doubtfully valid, as based on juvenile birds; *insularis* is synonym of *riciniata*. Three subspecies recognized.

Subspecies and Distribution.

E. s. riciniata (Bechstein, 1811) - N Moluccas, including Widi Is.
E. s. obiensis Rothschild, 1899 - Obi and Bisa in NC Moluccas.
E. s. squamata (Boddaert, 1783) - W Papuan Is and nearby Schildpad Is.

Descriptive notes. 27 cm. Red; bill orange; collar violet-blue, broad in some birds, absent in others; belly to undertail-coverts dark purplish blue; scapulars purple tipped black; greater wing-coverts and flight-feathers edged black; tail purple-red above, brownish red below; legs grey. Immature has underparts red with purplish edging. Race *riciniata* has violet collar usually extending from breast up onto hindcrown, red scapulars; *obiensis* has black scapulars.

Habitat. Lowland forest and forest edge, mangroves, disturbed forest and scrubby secondary growth adjacent to cultivation, coconut plantations; also montane primary forest up to 1220 m.

Food and Feeding. Flowering sago palm *Metroxylon*, unripe figs (*Ficus*), nectar of *Erythrina* flowers.
Breeding. No information from wild. In captivity: 2 eggs; incubation c. 27 days; nestling period c. 80 days.

Movements. Daily movements between main islands and small offshore islets noted; also noted to form large flocks, a habit which can make it common in one area and rare in another, suggesting some form of larger-scale nomadism.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. A range of 70,700-435,080 birds was estimated for the population of the N Moluccas, but survey work in 1990's gave figures of 115,400-283,700 for proposed Lalobata reserve (Halmahera) alone; around 2980 birds are estimated to have been trapped in 1991, suggesting that trade pressure is not excessively high, but it has been recommended that a biologically safe rate of annual offtake should be established.

Bibliography. Andrew (1992), Anon. (1993), Bechler *et al.* (1986), Bertagnolio (1973), Bishop (1992), Bräutigam & Humphreys (1992), Coates & Bishop (1997), Cooke (1990, 1995b), Hartert (1903a), Inskipp *et al.* (1996), Lambert (1993a, 1993c), Lambert & Young (1989), Linsley (1995), MacKinnon *et al.* (1995), Mees (1965), Milton (1988), Rand & Gilliard (1967), Ripley (1964), Smiet (1985), Sujatnika *et al.* (1995), White & Bruce (1986), Wright (1977).

7. Red Lory

Eos bornea

French: Lori écarlate

German: Rotlory

Spanish: Lori Rojo

Other common names: Moluccan/Moluccan Red(!)/Buru Lory

Taxonomy. *Psittacus borneus* Linnaeus, 1758, Borneo, India: error = Ambon.

All six *Eos* species comprise a superspecies. Various populations have been awarded separate races, on basis of purported size differences; however variability within these populations, or evidence of clines, suggests size cannot be used as a subspecific character. "*E. goodfellowi*" seems likely to represent immature of present species introduced to Obi. Proposed races *bernsteini* and *rothschildi* invalid, as variation is clinal. Two subspecies recognized.

Subspecies and Distribution.

E. b. cyanothorus (Vieillot, 1818) - Buru.

E. b. bornea (Linnaeus, 1758) - Ambon, Haruku, Saparua, Seram Laut, Watubela, Tayandu and Kai Is.

Descriptive notes. 31 cm. Red; bill orange to orange-yellow; bare orbital ring dark grey; secondary coverts and secondaries tipped black; primaries black with red speculum; lower tertials and undertail-coverts blue; tail dull red; legs dark grey. Immature duller, with less blue. Race *cyanothorus* darker.

Habitat. Lowland forest, mangroves, secondary forest and coconut plantations, chiefly in coastal areas, but up to 900 m on Seram and up to 1800 m on Buru.

Food and Feeding. Birds have been seen feeding in flowering *Eugenia* and *Erythrina* trees; remains of small insects found in stomachs.

Breeding. Nest-site prospection noted Aug-Sept; nestlings, Dec. Nest in hollow high in old tree. Nestling period in captivity 7-9 weeks.

Movements. Small groups frequently cross between islands in the Kai group. Seasonal fluctuations on Ambon have been claimed, with highest numbers Apr-Jul, but recent evidence does not support this idea.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Common to abundant, often in flocks up to 30. However, also heavily traded; international trade, 1985-1990, averaged 6538 birds per year, the USA being the main importer, and a general trend of declining exports may suggest declining numbers in the wild, a possibility which needs investigation. Certainly now scarce on Ambon and in Kai Is, and in Seram only common in remote areas; the commonest parrot on Buru, late 1989.

Bibliography. Andrew (1992), Anon. (1993), Auber (1938), Bowler & Taylor (1989), Buckell (1993), Coates & Bishop (1997), Courtney (1997b), Edwards & Nash (1992), Edworthy (1968), Holyoak (1970b, 1976), Inskipp *et al.* (1996), Jepson (1993), Marsden *et al.* (1997), Poulsen & Jepson (1996), Schodde & Mathews (1977), Siebers (1930), Smiet (1985), Stresemann (1914), Sujatnika *et al.* (1995), Walters (1975), Wheatley (1996), White & Bruce (1986).

8. Blue-streaked Lory

Eos reticulata

French: Lori réticulé

German: Strichellori

Spanish: Lori de las Tanimbar

Taxonomy. *Psittacus reticulatus* S. Müller, 1841, Moluccas.

All six *Eos* species comprise a superspecies. Monotypic.

Distribution. Tanimbar Is. Probably introduced to Kai Is and Damar, and apparently also Babar.

Descriptive notes. 31 cm. Similar to *E. cyanogenia* but broad blue stripe back from eye joins blue-streaked mantle; wing-coverts are red heavily edged black, primaries almost all black; thighs and flanks red. Immature has underparts edged blue-black, bill brownish.

Habitat. Primary forest inland, but apparently commoner in coastal secondary forest, plantations and mangroves.

Food and Feeding. No information; visits coconut plantations and sago palms.

Breeding. No information from wild. In captivity: 2 eggs; nestling period lasting as long as 12 weeks.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. Locally abundant, especially along coast, but trapping for the cagebird trade is heavy, with some habitat destruction. In the years 1983-1989 recorded international trade averaged 3198 birds annually, resulting in pressure to include the species on CITES I, but fieldwork in 1993 on Yamdena, which represents c. 55% of the species's range, revealed an estimated 220,000 ± 52,000 birds, and past catch-rates of less than 2% were judged unlikely to have caused any decline.

Bibliography. Andrew (1992), Cahyadi, Jepson & Manoppo (1994), Coates & Bishop (1997), Collar & Andrew (1994), Collar *et al.* (1994), Finsch (1900), Inskipp & Corrigan (1992), Lever (1987), McGregor (1991), Riley (1974), Smiet (1985), Sujatnika *et al.* (1995), Sweeney (1992), Wheatley (1996), White & Bruce (1986).

9. Black-winged Lory

Eos cyanogenia

French: Lori à joues bleues

German: Schwarzschulterlory

Spanish: Lori Alinegro

Other common names: Biak Red Lory

Taxonomy. *Eos cyanogenia* Bonaparte, 1850, Numfor.

All six *Eos* species comprise a superspecies. Monotypic.

Distribution. Islands of Biak-Supiori, Numfor, Manim and Meos Num in Geelvink Bay, NW New Guinea.

Descriptive notes. 30 cm; 120 g. Generally red; bill orange; purplish blue patch around eye extending through ear-coverts to sides of neck; upperwing-coverts, scapulars and back black; secondaries and primaries tipped black; thighs and flank spot black; tail black, outer feathers red on inner vanes, hence appears largely red below. Immature has purplish edges to body feathers.

Habitat. Birds feed in inland forest up to 460 m and roost in coconut plantations and coastal forest.

Food and Feeding. Recorded feeding in flowering trees.

Breeding. Courtship and nest prospecting observed Jun-Jul. In captivity: 2 eggs; incubation lasting 26 days; nestling period 75-87 days.

Movements. Birds are reported to be highly nomadic, but this is perhaps on a short-term basis without seasonal influence.

Status and Conservation. **VULNERABLE.** CITES II. A BirdLife "restricted-range" species. Status on Numfor and Manim unknown but likely to be very poor owing to the almost total clearance there of primary forest. Generally uncommon on Biak, though common on adjacent Supiori; at risk on former through

habitat loss and trade. International trade may be a serious threat: Indonesian records indicate 632, 1370 and 1370 birds exported, 1988-1990. Commercial importation into EC from Indonesia has been prohibited since Dec 1989.

Bibliography. Andrew (1992), Anon. (1993), Arndt (1992a), Beehler *et al.* (1986), Bishop (1982), Collar & Andrew (1988), Collar *et al.* (1994), Edwards & Nash (1992), Mayr & Meyer de Schauensee (1939a), Rand & Gilliard (1967), Sujatnika *et al.* (1995), Wright (1977).

10. Blue-eared Lory

Eos semilarvata

French: Lori masqué

German: Halbmaskenlory

Spanish: Lori de Seram

Other common names: Seram Lory

Taxonomy. *Eos semilarvata* Bonaparte, 1850, mountains of Seram.

All six *Eos* species comprise a superspecies. Monotypic.

Distribution. Mountains of Seram (Moluccas).

Descriptive notes. 24 cm. Red; bill orange; area from base of bill under eye and onto ear-coverts violet-blue; belly to undertail-coverts violet-blue; primaries black with a red speculum; secondaries tipped black; tertials tinged blue; tail reddish brown above; legs grey. Immature duller, with much less blue.

Habitat. Forest in mountains, above 1200 m; ranges out of forest up into tree heathers, occasionally down to 800 m.

Food and Feeding. Nectar, taking tree heather at highest altitudes.

Breeding. No information available.

Movements. No information; possibly some

altitudinal shifts occur seasonally.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. Reported to be common to locally abundant, with little current threat from logging, but species is now being trapped, and could also suffer from fires within its very limited altitudinal range; careful monitoring required, along with research to establish ecological requirements.

Bibliography. Andrew (1992), Bowler & Taylor (1989), Coates & Bishop (1997), Collar *et al.* (1994), Sujatnika *et al.* (1995), Walker & Reynolds (1983), Wheatley (1996), White & Bruce (1986).

Genus PSEUDEOS: J. L. Peters, 1935

11. Dusky Lory

Pseudeos fuscata

French: Lori sombre

German: Weißbüzzellori

Spanish: Lori Sombrio

Other common names: White-rumped/Dusky-orange Lory

Taxonomy. *Eos fuscata* Blyth, 1858, Manokwari (formerly Dorey), New Guinea.

In past considered polytypic, with nominate race confined to birds of Salawati and nearby mainland, and all other populations grouped in race *incondita*. Monotypic.

Distribution. New Guinea throughout, except for highest areas; also islands of Yapen and Salawati.

Descriptive notes. 25 cm; 117-192 g. Variable, with yellow and orange morphs. Generally dusky brown, with feathers of cheeks, hindneck and upper breast edged yellow; bill orange with naked orange skin around lower mandible; mid-crown, full ring around neck, breastband and central area of belly softly defined yellow, with yellow wing-edge, lower thighs and staining in central tail feathers; lower back and rump creamy to white, lightly barred dusky. Orange morph replaces yellow areas of plumage with orange except on crown; whitish edging to feathers of hindneck and upper breast; various intermediate forms occur. Immature has more

extensive yellow or orange markings on underparts, with dull yellowish back and rump, bill brownish.

Habitat. Hill rain forest and edge, secondary growth, partially cleared areas, groves and suburban parks, occasionally savanna and plantations, up to 2400 m.

Food and Feeding. Nectar and perhaps pollen of *Elaeocarpus sphaericus*, *Schefflera*, *Sloanea*, *Pittosporum ramiflorum*, coconut blossoms, also fruit. Seen flocking in fruiting mango and other cultivated trees; pupae of teak moth (*Hyblaia pueri*) witnessed being taken.

Breeding. Nov-Apr in E Highlands, though breeding condition male taken there in Aug; Jul in Irian Jaya. Nest in hole high in tall montane tree, e.g. eugenia, beeches. In captivity: 2 eggs; incubation lasting c. 24 days; nestling period c. 70 days.

Movements. Nomadic, with displacements occurring in response to periods of high or low flowering. However, there may be some very regular migrations across the central mountain chain. E Highlands population leaves after Apr, perhaps retreating to C lowlands.

Status and Conservation. Not globally threatened. CITES II. Common and highly gregarious, sometimes forming roosts of several thousand birds; in one area of SE New Guinea density estimated at 30 birds/km².

Bibliography. Andrew (1992), Baptista (1990), Beehler (1978b), Beehler *et al.* (1986), Bell (1970a, 1979, 1982), Bishop (1987), Coates (1985), Courtney (1997b), Desborough (1991), Diamond (1972a), Gilliard & LeCroy (1961), Gregory (1995a, 1995b), Gyldestolpe (1955b), Hoogerwerf (1971), Mack & Wright (1996), Mackay (1970), Majnep & Bulmer (1977), Mayr & Rand (1937), Pagel & Greven (1990), Peters (1935), Rand (1942b), Rand & Gilliard (1967), Ripley (1964), Schodde & Hitchcock (1968), Schönwetter (1967), Wenner (1973, 1975).

Genus TRICHOGLOSSUS

Vigors & Horsfield, 1827

12. Ornate Lorikeet

Trichoglossus ornatus

French: Loriquet orné

German: Schmucklory

Spanish: Lori Adornado

Other common names: Ornate Lory

Taxonomy. *Psittacus ornatus* Linnaeus, 1758, America; error = Sulawesi.

Forms a superspecies with *T. haematodus*. Monotypic.

Distribution. Sulawesi and adjacent offshore islands.

Descriptive notes. 25 cm. Bill orange-red; crown and ear-coverts purplish black; face and postocular stripe red; side of neck yellow; throat and breast red broadly barred deep blue; belly green with some yellow edges, becoming regular on thighs and below; hindneck to tail green, wings with yellow leading edge and underwing-coverts yellow; tail below dull yellow. Immature has brownish bill and more yellow on belly.

Habitat. Peat and freshwater swamp forest, woodland, secondary forest and forest edge, bush, and near cultivation including coconut plantations, from sea-level to 1000 m in N &

C Sulawesi, to 1500 m in S.

Food and Feeding. May concentrate in large numbers to feed in flowering trees; *Tectona* and *Casuarina* seeds reported.

Breeding. Breeding condition birds, Sept-Oct. In captivity: 2 eggs; incubation 27 days; nestling period 80 days.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Reported to be particularly common in coconut plantations and around villages in some parts; common in Dumoga-Bone National Park.

Bibliography. Andrew (1992), Andrew & Holmes (1990), van Bemmelen & Voous (1951), Bertagnolio (1970), Bishop (1992), Coates & Bishop (1997), Coomans de Ruiter & Maurenbrecher (1948), Fraser & Henson (1996), Harrison & Holyoak (1970), Holmes & Philipps (1996), Stresemann (1940), Watling (1983), Wheatley (1996), White (1977), White & Bruce (1986).

13. Rainbow Lorikeet

Trichoglossus haematodus

French: Loriquet à tête bleue

German: Allfarblori

Spanish: Lori Arcoiris

Other common names: Green-naped/Red-breasted/Coconut Lorikeet, Rainbow Lory; Red-collared Lorikeet (*rubritorquis*)

Taxonomy. *Psittacus haematod.* [sic] Linnaeus, 1771, Ambon.

Forms a superspecies with *T. ornatus*. Treatment of *rubritorquis* as a separate species is unsustainable without an extensive revision of whole of present species; birds of Lesser Sunda are at least as distinctive, and the case of the small green *weberi* presents a particular challenge to the present arrangement, although the view that it is closer to *T. euteles* than to present species appears mistaken. Three broad groups may be defined: (1) breast red and unbarred (first four races listed below); (2) breast yellow or green without dark barring (*fortis* to *flavotectus*); and (3) breast red and in general heavily to faintly barred (*rosenbergii* through to *moluccanus*); *rubritorquis* might be considered to form a fourth group. New Guinean populations of nominate race sometimes separated as race *berauensis*; proposed race *caeruleiceps* probably not separable from *nigroregularis*. Twenty subspecies recognized.

Subspecies and Distribution.

T. h. mitchellii G. R. Gray, 1859 - Bali and Lombok.

T. h. forsteni Bonaparte, 1850 - Sumbawa.

T. h. djampeanus Hartert, 1897 - Tanahjampea.

T. h. stresemanni Meise, 1929 - Kalaotoa.

T. h. fortis Hartert, 1898 - Sumba.

T. h. weberi (Büttikofer, 1894) - Flores.

T. h. capistratus (Bechstein, 1811) - Timor.

T. h. flavotectus Hellmayr, 1914 - Wetar and Romang.

T. h. rosenbergii Schlegel, 1873 - Biak I, off N Irian Jaya.

T. h. intermedius Rothschild & Hartert, 1901 - N New Guinea and Manam I from R Sepik E to Astrolabe Bay.

T. h. haematodus (Linnaeus, 1771) - S Moluccas and W Papuan Is E to NW New Guinea as far as Humboldt Bay and S New Guinea as far as upper R Fly; possibly W Kai Is.

T. h. nigrogularis G. R. Gray, 1858 - E Kai Is, Aru Is (except Spirit I) and S New Guinea from lower R Fly to Princess Marianne Straits.

T. h. brooki Ogilvie-Grant, 1907 - Spirit I, Aru Is.

T. h. micropteryx Stresemann, 1922 - E New Guinea E from Huon Peninsula in N, including Bagabag I, and Hall Sound in S.

T. h. nesophilus Neumann, 1929 - Ninigo and Hermit Groups, W of Manus.

T. h. flavicans Cabanis & Reichenow, 1876 - Admiralty Is and New Hanover.

T. h. massena Bonaparte, 1854 - Karkar I, Bismarck Archipelago, Solomon Is and Vanuatu.

T. h. deplanchii J. Verreaux & Des Murs, 1860 - New Caledonia and Loyalty Is.

T. h. moluccanus (J. F. Gmelin, 1788) - Torres Strait islands, E & SE Australia and Tasmania.

T. h. rubritorquis Vigors & Horsfield, 1827 - N Australia.

Possibly introduced (*rubritorquis*) to Kisar, E of Timor; feral (*moluccanus*) in Perth (Western Australia).

Descriptive notes. 25-30 cm; 75-157 g. Bill orange to red; head blue to deep brown lightly flecked pale violet; nuchal collar yellow; rest of upperparts and tail green, latter dusky yellow below; breast red barred blue-black; belly dark green; thighs and undertail-coverts yellow barred dark green; underwing-coverts orange with broad yellow underwing bar. Immature duller, bill brownish. Races from Bali to Kalaotoa lack barring on breast; *fortis*, *capistratus* and *flavotectus* have orange-yellow breasts; *weberi* is small and all-green, yellowish green on breast; other races exhibit various permutations of basic *haematodus* coloration.

oration, e.g. different intensities and extent of blue on head, of colour of belly, barring on breast; in *moluccanus*, breast barring variable from slight to non-existent. Race *rubritorquis* fairly distinct, with clear orange-red breast, greenish black belly and broad orange-red nuchal collar.

Habitat. Most types of lowland and lower montane wooded country, including mangroves, nypa forest, freshwater swamp forest, primary rain forest, secondary growth, scrubby monsoon forest, savanna, riparian woodland, mallee, coconut and other plantations, gardens and suburban areas; tends to favour edges and disturbed vegetation rather than interior of closed-canopy formations. Birds at least visit but perhaps also survive year-round in scrub and plantations on very small atolls. Typically from sea-level to 500-700 m, but often higher depending on island, e.g. 2150 m on Lombok, 1200 m on Sumbawa, 1400 m on Flores and occasionally on Seram, and 2440 m in one part of New Guinea. On Kolombangara densities higher in montane (900-1200 m) than lowland forest, in contrast to *Chalcopsitta cardinalis*.

Food and Feeding. Nectar and pollen from native trees and shrubs, particularly *Eucalyptus* in Australia and Timor; also from *Pittosporum*, *Grevillea*, *Spathodea*, *Metroxylon*, *Schefflera*,

Pterocymbium, *Erythrina*, *Banksia*, *Melaleuca*, *Angophora*, *Bauhinia*, *Cocos* (of which the species is an important pollinator), *Xanthorrhoea*, *Bombax*, *Verticordia*, *Bletharocarya*, bottlebrush (Myrtaceae) and mistletoes (Loranthaceae); fruit of *Ficus*, *Trema*, *Muntingia*, citrus, papaya and mangoes opened by fruit-bats, seeds of *Cassia* and *Casuarina*, and pupae of the poinciana moth (*Pericyma cruegeri*). Now commonly use introduced plants in Australia including grains of *Sorghum*, seeds of *Solanum*, ripening cones of *Pinus*, fruit of *Annona*, *Cinnamomum*, berries of *Schinus*, apples and pears. Seen to eat at base of ant-plants *Myrmecodion*. In one part of Australia found to use 43 species of plant, 87% of the diet consisting of flowers.

Breeding. Activity throughout most of year in New Guinea; Feb-Aug on Flores; nest-prospecting Nov-Dec on Buru; Aug-Jan in Australia and Vanuatu; in Solomons Aug, when copulation and nests with chicks observed, but also Nov. Nest in deep unlined hole in limb or trunk of large tree; exceptionally, on Manus (Admiralty Is), nests in ground on tiny predator-free offshore islets. Eggs 1-3; incubation lasts c. 25 days; nestling period 7-8 weeks.

Movements. Local abundance on tropical islands may vary considerably with the phenology of flowering trees, but in some places, e.g. C New Guinea, the species has been judged sedentary. On groups of small islands birds commonly move from one to the other daily. In Australia birds are nomadic, presence or absence, or at least quantities, being governed by flowering events; this is particularly pronounced in S of range. Daily movements to offshore islands to and from feeding/roosting areas occur.

Status and Conservation. Not globally threatened. CITES II. Rare on Bali, but possibly a recent colonizer there from Lombok, although formerly common near Lake Bratan. Weakly marked race *djampeanus* likely to have been trapped to near-extinction on Tanahjampea, to which it is endemic; trapping has also rendered the population on Ambon very small. Common, Timor and Flores, but rare on Sumbawa probably owing to overtrapping for trade. Abundant, Seram. Abundant throughout much of New Guinea, and considered possibly the commonest parrot on the island; as many as 80 birds/km² estimated in one area of SE New Guinea. Common, Karkar. Common, New Britain. Abundant, New Georgia. Widespread in small numbers, Bougainville; elsewhere considered abundant in N Solomons. Fairly common, New Caledonia and adjacent islands. Abundant in N Australia, becoming less plentiful in SE and although once common in Victoria it is now relatively rare, but increasing around Melbourne and Canberra and still moderately common in South Australia; rare in Tasmania, where may be only visitor.

cm 10

PLATE 30

14. Olive-headed Lorikeet

Trichoglossus euteles

French: Lorient eutèle **German:** Gelbkopflori **Spanish:** Lori Humilde
Other common names: Perfect Lorikeet

Taxonomy. *Psittacus euteles* Temminck, 1835, Timor. Forms a broad superspecies with *T. flavoviridis*, *T. johnstoniae*, *T. rubiginosus* and *T. chlorolepidotus*. Some authors consider *T. haematodus weberi* as belonging to present species. Names *ochrocephalus* and *alorenensis* are synonyms of *euteles*. Monotypic.

Distribution. Timor and adjacent small islands from Lomblen E to Babar (Lesser Sundas).

Descriptive notes. 25 cm. Bill orange-red; head olive mustard with indistinct pale yellow streaks on crown; upperparts green, with green of nape extending as an indistinct but usually complete broad collar around throat; underparts below throat greenish yellow. Immature duller, head greener.

Habitat. Primary montane forest, secondary growth and savanna woodland at roughly 1000-2300 m, apparently replacing *T. haematodus* at these elevations on Timor, although occasionally found at sea-level; in lowlands on other islands.

Food and Feeding. No information other than

visits flowering trees and shrubs.

Breeding. No information from wild. In captivity: 3 eggs; incubation period 23 days.

Movements. Birds may descend below 1000 m in the dry season and disperse throughout the lowlands, but studies needed.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Local trade in the species exists.

Bibliography. Andrew (1992), Coates & Bishop (1997), Harrison & Holyoak (1970), Inskipp *et al.* (1996), Jepson & Monk (1995), Mayr (1944b), Noske (1995), Russell (1971), Sujatnika *et al.* (1995), Wheatley (1996), White & Bruce (1986).

15. Yellow-and-green Lorikeet

Trichoglossus flavoviridis

French: Lorient jaune et vert **German:** Celebeslori **Spanish:** Lori Verdigualdo
Other common names: Meyer's Lorikeet

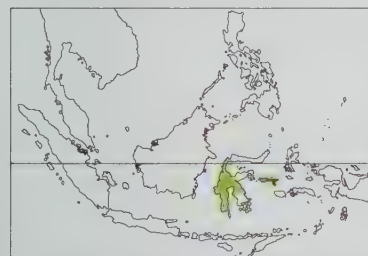

Taxonomy. *Trichoglossus flavoviridis* Wallace, 1863, Sula Islands.

Has on occasion been placed in genus *Psitteuteles*. Forms a broad superspecies with *T. euteles*, *T. johnstoniae*, *T. rubiginosus* and *T. chlorolepidotus*. Proposed races *bonthainensis* and *edithae* included in *meyeri*. Two subspecies currently recognized.

Subspecies and Distribution.

T. f. meyeri Walden, 1871 - Sulawesi.

T. f. flavoviridis Wallace, 1863 - Sula Is.

Descriptive notes. 21 cm. Bill orange; base of bill dusky brown with yellow edges spreading as almost pure yellow on crown and as yellow and green barring on underparts, becoming light and dark green barring on thighs and undertail-coverts; narrow line on hindcrown and sides of neck dusky; remainder of upperparts green. Immature more greenish. Race *meyeri* smaller, with much less yellow on head, and feathers of breast and upper belly greenish yellow edged with dark green.

Habitat. Lowland to upper montane forest and secondary growth, occasionally entering open country for access to flowering trees; appears

to replace *T. ornatus* at higher elevations on Sulawesi, although the two co-occur at forest margins; generally at 800-2400 m.

Food and Feeding. Blossoms of *Erythrina* and *Euphorbia* recorded.

Breeding. Jul, possibly Nov. One nest was high in a dead tree in moss forest at 2400 m. In captivity: 2 eggs; incubation lasting c. 23 days; nestling period c. 65 days or less.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Locally common. On Taliabu, Sula Is, most numerous in montane forest, which is still relatively secure and the target of a proposed reserve, but also common in degraded lowland areas.

Bibliography. Andrew (1992), van den Berg & Bosman (1986), Buckell (1996b, 1996c, 1996d), Coates & Bishop (1997), Davidson *et al.* (1995), Holmes & Philipps (1996), Low (1997b), Rozendaal & Dekker (1989), Serpell (1981, 1982, 1989), Stresemann (1940), Sujatnika *et al.* (1995), Watling (1983), Wheatley (1996), White & Bruce (1986).

16. Mindanao Lorikeet

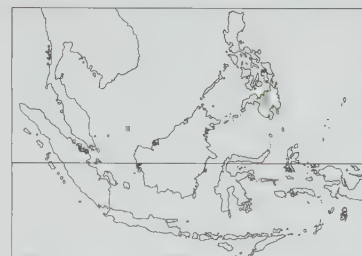

Trichoglossus johnstoniae

French: Lorient de Johnstone **German:** Mindanaolori **Spanish:** Lori de Mindanao
Other common names: (Mrs) Johnstone's/Apo Lorikeet

Taxonomy. *Trichoglossus johnstoniae* Hartert, 1903, Mount Apo, 8000 feet (c. 2400 m), Mindanao. Occasionally placed in genus *Psitteuteles*. Forms a broad superspecies with *T. euteles*, *T. flavoviridis*,

T. rubiginosus and *T. chlorolepidotus*. Population on Mt Malindang given name *pistra* but characters slight and intermediate birds now known from intervening areas. Monotypic.

Distribution. At least six montane areas of C Mindanao (SE Philippines).

Descriptive notes. 20 cm; 48-62 g. Bill reddish orange; front of head from forehead to chin and anterior ear-coverts red, scaled yellow, shading to green scaled yellow on rest of crown and face; purplish black line from lores through and behind eye to nape; underparts yellow broadly scaled green; upperparts green; tail green above, dusky yellowish below. Immature has less red on face, white orbital skin, darker bill.

Habitat. Montane forest and forest edge above 1000 m, with daily altitudinal movement, roosting in lower areas in the evening and returning to higher forest at sunrise.

Food and Feeding. Seen taking nectar from trees with scarlet blossoms; nothing else recorded.

Breeding. Breeding condition birds indicate Mar-May. In captivity: apparently 2 eggs; incubation lasting only 2 (probably 3) weeks; nestling period 5 weeks.

Movements. Seasonal or nomadic displacements in search of food unrecorded, but each evening birds make downslope flights to roosting areas and each morning return upslope to forage.

Status and Conservation. VULNERABLE. CITES II. A BirdLife "restricted-range" species. Recent fieldwork suggests it is now very uncommon, and that habitat destruction is constraining the lower reaches of its altitudinal range. Nevertheless, two of its six known mountain sites (Apo and Katanglad) are protected under the National Integrated Protected Areas Scheme (NIPAS), one (Malindang) has been declared a national park and will also qualify under NIPAS, and one (Matutum) is being targeted for early conservation attention.

Bibliography. Collar *et al.* (1994), Delacour & Mayr (1946), Dickinson *et al.* (1991), DuPont (1971), Goodfellow (1906), Hachisuka (1931b, 1934), Harrison & Holyoak (1970), Johnstone (1907), Rand & Rabor (1959, 1960), Ripley & Rabor (1961), Sargeant (1992), Sweeney (1997c, 1997g), Wheatley (1996).

17. Pohnpei Lorikeet

Trichoglossus rubiginosus

French: Lorient de Ponapé **German:** Kirschlori **Spanish:** Lori de Ponapé
Other common names: Pohnpei/Ponape Lory

Taxonomy. *Chalcopsitta rubiginosa* Bonaparte, 1850, islands of Barabai and Gebe; error = Pohnpei, Caroline Islands.

Forms a broad superspecies with *T. euteles*, *T. flavoviridis*, *T. johnstoniae* and *T. chlorolepidotus*. Monotypic.

Distribution. Pohnpei, E Caroline Is.

Descriptive notes. 24 cm; 70-85 g. Dark reddish maroon throughout, darkest on head but with vague greyish scaling on rest of body; orange bill, grey legs, wing feathers dark yellowish grey, tail greyish basally, dull yellow distally. Female has yellowish bill and greyish white (as against yellow-orange) iris. Immature like adult.

Habitat. Forest and plantations.

Food and Feeding. Nectar and pollen of coconut palms; also fruit and fly larvae.

Breeding. Breeding condition birds in Nov. Nest in hole in coconut palm or other large tree. 1 egg. No further information.

Movements. No information available.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Common, especially in lowland plantations.

Bibliography. Baker (1951), Dahl (1986), Mayr (1945), Pratt *et al.* (1987).

18. Scaly-breasted Lorikeet

Trichoglossus chlorolepidotus

French: Lorient vert **German:** Schuppenlori **Spanish:** Lori Escumaviverde

Taxonomy. *Psittacus chlorolepidotus* Kuhl, 1820, New South Wales.

Forms a broad superspecies with *T. euteles*, *T. flavoviridis*, *T. johnstoniae* and *T. rubiginosus*. Formerly considered polytypic, with birds of N Queensland placed in race *neglectus*. Monotypic.

Distribution. E Australia. Population near Melbourne derived from escapes.

Descriptive notes. 23 cm; 70-89 g. Generally green; bill orange-red; breast and belly green heavily barred yellow; underside of wings largely red. Immature has dusky brown bill.

Habitat. Lowland wooded areas, flowering heathlands, *Melaleuca* swamps, urban parks and gardens, cultivated areas.

Food and Feeding. At least 25 species of plant recorded in diet, 99% consisting of flowers. Those of *Eucalyptus* are main food, but other important genera are *Banksia*, *Callistemon*, *Melaleuca* and *Tristania*. In particular, *E. tereticornis* and *E. pilularis* formed nearly 50% of food in one study, with a further 25% being

supplied by *E. drepanophylla*, *C. viminalis* and *M. quinquenervia*. Other food plants include *Erythrina*

indica, *Schefflera actinophylla*, *Pithecellobium saman*, *Grevillea robusta*, *Banksia serrata*, *Casuarina* and grass trees *Xanthorrhoea*. Although not so adaptable to exotic foods as *T. haematodus*, camphor laurel *Cinnomomum camphora* fruit now a regular seasonal component of some groups of birds. Recorded attacking ripening sorghum crops.

Breeding. May-Feb. in N of range apparently related to rainfall; Aug in Victoria. Unlined nest in hollow limb or hole high in tree. Eggs 2, occasionally 3; incubation lasting c. 25 days; nestling period c. 8 weeks.

Movements. Nomadic in response to flowering events, although in centre of range some birds seem to be present throughout the year.

Status and Conservation. Not globally threatened. CITES II. Common in C of range in SE Queensland and NE New South Wales, where large flocks occur; at N and S edges of range progressively rarer.

Bibliography. Blakers *et al.* (1984), Bruce (1973), Cannon (1984a, 1984c), Courtney (1997b), Forshaw (1981b), Gosper & Gosper (1996), Hamley (1977), Lavery (1970), Leggett & Woodall (1987), Lindsey, T.R. (1992), Macdonald (1988), Mitchell (1979), Pizzey & Doyle (1980), Rose (1997b), Schodde & Tidemann (1986), Serpell (1981, 1982, 1989), Simpson & Day (1996), Trounson & Trounson (1987), Wyndham & Cannon (1985).

Genus *PSITTEUTELES* Bonaparte, 1854

19. Varied Lorikeet

Psitteuteles versicolor

French: Loriqueet versicolore

German: Buntlori

Spanish: Lori Versicolor

Taxonomy. *Trichoglossus versicolor* Lear, 1831, Cape York, Queensland. Sometimes placed in genus *Trichoglossus*. Monotypic.

Distribution. N Australia from Kimberley division, Western Australia, to NE Queensland.

Descriptive notes. 18-19 cm; 51-62 g. Bill orange-red; forehead to mid-crown red; bare orbital ring white; ear-coverts tufted yellow; rest of head bluish green with narrow yellow streaking which extends over soft pink breast and pale green rest of underparts; mantle and wing-coverts green streaked with yellow; wings and tail duller green. Female has duller, less extensive red on crown. Immature duller, crown largely green, bill brownish.

Habitat. Wooded country, being especially attracted to paperbarks (*Melaleuca*) and eucalypts bordering streams and water-holes.

Food and Feeding. Pollen and nectar from the

flowers of bloodwoods *Eucalyptus terminalis* and *E. polycarpa*, also *E. tetradonta* and *E. pruinosa*, the paperbark *Melaleuca leucodendron*, kapok trees (*Cochlospermum heteronemum*), *Bauhinia* trees and *Grevillea pteridifolia*.

Breeding. Chiefly Apr-Aug, although recorded at all times of year. Nest in hollow limb or hole fairly high in tree. Eggs 2-5; in captivity, incubation lasts 20-23 days, and nestling period around 40 days.

Movements. Visitor only to E coast of Cape York Peninsula, and elsewhere nomadic in response to availability of blossom.

Status and Conservation. Not globally threatened. CITES II. Generally considered to be common in most habitats, but owing to nomadism it can disappear from some areas for long periods of time.

Bibliography. Blakers *et al.* (1984), Courtney (1997b), Forshaw (1981b), Lindsey, T.R. (1992), Macdonald (1988), Pizzey & Doyle (1980), Schodde & Tidemann (1986), Serpell (1981, 1982, 1989), Simpson & Day (1996), Sindel (1987), Storr (1977, 1980), Tarr (1963), Trounson & Trounson (1987).

20. Iris Lorikeet

Psitteuteles iris

French: Loriqueet iris

German: Irislori

Spanish: Lori Iris

Other common names: Iris Lory

Taxonomy. *Psittacus iris* Temminck, 1835, Timor.

Sometimes placed in *Trichoglossus* or even *Neopsittacus*. Validity of race *rubripileum* questionable, and claimed differences may be due to age or individual variation. Three subspecies recognized.

Subspecies and Distribution.

P. i. iris (Temminck, 1835) - W Timor.

P. i. rubripileum (Salvadori, 1891) - E Timor.

P. i. wetterensis (Hellmayr, 1912) - Wetar.

Descriptive notes. 20-22 cm. Bill orange red; crown red shading to blue-edged purple on hindcrown, bordered yellow on nape and green on upper mantle; broad patch behind eye purplish; rest of face and underparts yellowish green, latter with irregular narrow green bars; wings and tail green. Female has green forehead with some red. Immature like female with less red, bill brownish. Race *rubripileum* can have crown all red, or with some blue or green at rear; *wetterensis* larger, with more extensive red around crown.

Habitat. Primary and tall secondary monsoon forest, hill and lower montane forest and wood-

land, from sea-level to 1500 m, mainly above 600 m; on Wetar seen in scattered trees around a village.

Food and Feeding. Visits flowering trees including *Sesbania*.

Breeding. No information from wild. In captivity: 2 eggs; incubation lasting 23 days; nestling period 67 days.

Movements. No information, but predicted to wander in search of flowering trees.

Status and Conservation. VULNERABLE. CITES II. A BirdLife "restricted-range" species. Judged the least common of the three lorikeets on Timor in 1974, but presumably still relatively secure on a still partly forested and fairly large island; probably locally common at higher elevations on Mt Mutis. Species still present on Wetar in 1990. In period 1985-1990 reported international trade averaged 139 birds per year, but even this fairly modest rate may be excessive and in 1989 the EC banned the importation of the species from Indonesia.

Bibliography. Andrew (1992), Anon. (1993), Coates & Bishop (1997), Collar *et al.* (1994), Kyme (1975), Mayr (1944b), Noske (1995), Noske & Saleh (1993), Sujatnika & Jepsen (1995), Sujatnika *et al.* (1995), Walters (1984), Wheatley (1996), White & Bruce (1986).

21. Goldie's Lorikeet

Psitteuteles goldiei

French: Loriqueet de Goldie

German: Veilchenlori

Spanish: Lori de Goldie

Other common names: Red-capped Streaked Lorikeet/Lory

Taxonomy. *Trichoglossus Goldiei* Sharpe, 1882, Astrolabe Mountains, New Guinea.

Sometimes placed in genus *Trichoglossus*, although present species possibly closer to *Charmosyna*. Monotypic.

Distribution. C New Guinea from Weyland Mts in W to Owen Stanley Range in E.

Descriptive notes. 19 cm; 45-61 g. Black bill; crown red with blackish line from loreal area back to hindcrown, bluish under eye, deep pink hood from throat to nape with regular dark streaking which extends over yellowish green mantle and undersides; upper back and tail green variably washed slightly brownish, wings and lower back dark green; yellow band across underside of flight-feathers. Female has duller, less extensive red in crown. Immature has green crown.

Habitat. In habits primary montane forest at mid-elevations, but ranging to sea-level and up to 2800 m where recorded in disturbed

Nothofagus-*Podocarpus* forest.

Food and Feeding. Flowers of *Elaeocarpus*, *Poikilospermum*, *Eucalyptus*, *Grevillea* and *Dimorphanthera*; apparently no other certain sources, but psyllid lerps may be an important food that draws birds into casuarinas.

Breeding. Sept-Oct. Nest in base of dead fronds in lower crown of *Pandanus* tree, in one case at moss forest/grassland edge. Eggs 2; in captivity incubation 23 days, nestling period 2 months.

Movements. Apparently nomadic in relation to flowering schedules of several canopy trees and lianas; for example, absent from an upland area of C Papua New Guinea, Dec-Jan, when known to be present in large numbers in a valley well to N.

Status and Conservation. Not globally threatened. CITES II. Generally fairly scarce but locally common (e.g. near Tari Gap, Papua New Guinea), presumably in response to local food availability.

Bibliography. Andrew (1992), Beehler (1978b), Beehler, Burg *et al.* (1994), Beehler, Pratt & Zimmerman (1986), Bell (1982), Coates (1985), Courtney (1997b), Diamond (1972a), Frith & Frith (1992), Gilliard & LeCroy (1961), Gregory (1995a, 1995b), Joshua (1993), Layton (1969), Mack & Wright (1996), Majnep & Bulmer (1977), Mayr & Rand (1937), Merck (1983), Plath (1951), Rand & Gilliard (1967), Vanderhoof (1993), Walters (1984).

Genus *LORIUS* Vigors, 1825

22. Chattering Lory

Lorius garrulus

French: Lori noire

German: Prachtlori

Spanish: Lori Gárrulo

Other common names: Yellow-backed Lory (*flavopalliatu*s)

Taxonomy. *Psittacus garrulus* Linnaeus, 1758, Halmahera.

Genus name formerly given as *Domicella* Wagler, 1832, since *Lorius* Boddaert, 1783, applicable to *Eclectus*, had priority; however, Boddaert's name was officially suppressed in 1970, leaving *Lorius* Vigors, 1825, as the correct name for present species and congeners. Forms a superspecies with *L. domicella*, *L. lory* and *L. hypnochrous*. Three subspecies recognized.

Subspecies and Distribution.

L. g. morotaianus (van Bemmelen, 1940) - Morotai and Rau, N Moluccas.

L. g. garrulus (Linnaeus, 1758) - Halmahera and adjacent islands.

*L. g. flavopalliatu*s Salvadori, 1877 - Bacan, Obi, Kasiruta and Mandiole.

Descriptive notes. 30 cm. Mainly red, mantle sometimes with traces of yellow spotting; bill orange, basally dark; thighs and wings dull green; bend of wing and underwing-coverts yellow; broad red band across underside of primaries; tail distally dark green. Immature has brownish bill. Race *flavopalliatu*s has bold yellow patch on mantle and slightly brighter green wings; *morotaianus* has slight yellow mantle patch.

Habitat. Chiefly canopy of primary lowland and hill forest and edges, logged forest and mature secondary woodland adjacent to cultivated land, sometimes visiting coconut plan-

tations. Ranges from sea-level to 1000 m on Halmahera, to 1300 m on Bacan, and to 730 m on Obi; in proposed Lalobata reserve (Halmahera), densities found to increase with altitude.

Food and Feeding. Almost no information; nectar from various flowering trees, including coconut palms.

Breeding. Jun-Nov or beyond. Nest in hole typically in swelling on main trunk 20-25 m up in 30-35 m high tree; also in dead trees and broken palm stems. In captivity: 2 eggs; nestling period 76 days.

Movements. No information.

Status and Conservation. **VULNERABLE.** CITES II. A BirdLife "restricted-range" species. Population estimates for 1991 were: nominate *garrulus* 31,220-220,009; *flavopalliatius* 11,292-48,411 birds, with 4546-32,267 in Bacan group and 6746-16,144 in Obi group; *morotaianus* 3848-27,120. However, survey work in 1990's gave figures of 56,600-105,900 birds (nominate) for proposed Lalobata reserve alone, indicating that species might be more secure than was feared. Nevertheless, this species, reputedly a good talker, is one of the most important in domestic trade in Indonesia, and trapping pressure is very high: a minimum 9600 birds were estimated caught in 1991, a total which needs to be reduced by a factor of 10 to ensure sustainability. Habitat destruction in the Moluccas is still not a major concern, but logging will duly occur throughout the islands.

Bibliography. Andrew (1992), Anon. (1993), Bräutigam & Humphreys (1992), Coates & Bishop (1997), Collar *et al.* (1994), Collard (1965), Hartert (1903a), Lambert (1993a, 1993c), Lendon (1946), Linsley (1995), MacKinnon *et al.* (1995), Milton (1988), Pagel & Greven (1990), Robson (1994), Smiet (1985), Sujatnika & Jepson (1995), Sujatnika *et al.* (1995), Waugh (1996a, 1996b), Wheatley (1996), White & Bruce (1986).

23. Purple-naped Lory

Lorius domicella

French: Lori des dames

German: Erzlori

Spanish: Lori Damisela

Other common names: Purple-capped Lory

Taxonomy. *Psittacus Domicella* Linnaeus, 1758, Ambon.

Genus name formerly given as *Domicella* Wagler, 1832, since *Lorius* Boddaert, 1783, applicable to *Eclectus*, had priority; however, Boddaert's name was officially suppressed in 1970, leaving *Lorius* Vigors, 1825, as the correct name for present species and congeners. Forms a superspecies with *L. garrulus*, *L. lory* and *L. hypoinchrous*. Proposed species "*L. tibialis*" (Blue-thighed/Jamrach's Lory) was probably described from an aberrant specimen of present species. Species name sometimes erroneously spelt *domicellus*, but is a diminutive feminine noun. Monotypic.

Distribution. Seram and Ambon (S Moluccas). Feral population established on Buru, but probably now extinct.

Descriptive notes. 28 cm. Mainly red; bill orange; crown above line through eye to nape black, shading at rear to violet; variable yellow band across upper breast; thighs purplish blue; wings green with pale whitish blue at bend; underwing-coverts blue with broad yellow band across underside of flight-feathers; tail red tipped brownish red. Immature has deeper violet on nape, broader yellow band on breast, brownish bill.

Habitat. Hill forest, with a restricted altitudinal range from 400 m up to at least 1050 m; densities apparently highest in upper parts of this range, particularly above 800 m.

Food and Feeding. Recorded feeding acrobatically on pendant seeds of rattan and other plants. No further information available.

Breeding. No information from wild. In captivity: 2 eggs; incubation c. 24 days; nestling period c. 3 months.

Movements. No information; apparently sedentary.

Status and Conservation. **VULNERABLE.** CITES II. A BirdLife "restricted-range" species. Apparently a naturally low-density bird, uncommon to rare on Seram, with no recent reports from Ambon or Buru. Fair numbers trapped and kept by local villagers at Manusela National Park, Seram. **Bibliography.** Andrew (1992), Anon. (1994, 1997), Bowler & Taylor (1989, 1993), Coates & Bishop (1997), Collar & Andrew (1988), Collar *et al.* (1994), Inskipp *et al.* (1996), Kuah (1993), Robson (1988), Siebers (1930), Smiet (1985), Spence (1955), Stresemann (1914), Sujatnika *et al.* (1995), Wheatley (1996), White & Bruce (1986).

24. Black-capped Lory

Lorius lory

French: Lori tricolore

German: Frauenlori

Spanish: Lori Tricolor

Other common names: Western Black-capped/Tricoloured Lory

Taxonomy. *Psittacus Lory* Linnaeus, 1758, East Indies = north-western New Guinea.

Genus name formerly given as *Domicella* Wagler, 1832, since *Lorius* Boddaert, 1783, applicable to *Eclectus*, had priority; however, Boddaert's name was officially suppressed in 1970, leaving *Lorius* Vigors, 1825, as the correct name for present species and congeners. Forms a superspecies with *L. garrulus*, *L. domicella* and *L. hypoinchrous*. Seven subspecies recognized.

Subspecies and Distribution.

L. l. lory (Linnaeus, 1758) - W Papuan Is and Vogelkop (NW New Guinea).

L. l. cyanauchen (S. Müller, 1841) - Biak in Geelvink Bay.

L. l. jobiensis (A. B. Meyer, 1874) - Yapen and Mios Num in Geelvink Bay.

L. l. viridicrissalis de Beaufort, 1909 - N New Guinea from Humboldt Bay to Mamberano R.

L. l. salvadorii A. B. Meyer, 1891 - NE New Guinea from Aitape area to Astrolabe Bay.

L. l. erythrothorax Salvadori, 1877 - throughout S & E New Guinea except where replaced by *somu*.

L. l. somu (Diamond, 1967) - Papua New Guinea, in area between R Fly and R Purari.

Descriptive notes. 29-33 cm; 163-260 g. Bill orange, cere black; crown above line through eye purplish black; rest of head and throat red, shading to pink on narrow hindneck collar; upper mantle blackish with dark blue tinge, extending down sides of neck to join irregular blackish markings on breast, shading to purplish on belly, thighs and vent; sides of breast and flanks red; underwing-coverts red bordered by broad yellow band across base of flight-feathers, tips blackish; wings green above; tail above red, distally blue-black, below dull olive yellow. Immature has underwing-coverts blue. Race *erythrothorax* has breast red, less blue on nape; *somu* similar without any blue on nape; *cyanauchen* similar but blackish crown merges with blue nape; *salvadorii* like nominate but underwing-coverts dark blue; *viridicrissalis* similar but darker on nape, underwing-coverts mainly black; *jobiensis* like *salvadorii* but rosier breast, nape lighter blue.

Status and Conservation. Not globally threatened. CITES II. Generally a common though not abundant bird throughout its range, with 40 birds/km² estimated in on area of SE New Guinea.

Bibliography. Andrew (1992), Beehler (1978b), Beehler *et al.* (1986), Bell (1970c, 1982), Burgess (1921), Coates (1985), Courtney (1997b), Diamond (1967, 1972a), Gregory (1995a, 1995b), Hicks (1992), Hoogerwerf (1971), Mack & Wright (1996), Mayr & Meyer de Schauensee (1939a), Mayr & Rand (1937), Pearson (1975b), Peckover & Filewood (1976), Rand (1942a), Rand & Gilliard (1967), Ripley (1964), Rothschild (1931), Schodde & Hitchcock (1968), Watson *et al.* (1962).

25. Purple-bellied Lory

Lorius hypoinchrous

French: Lori à ventre violet

German: SchwarzsteiBlori

Spanish: Lori Ventrivinoso

Other common names: Eastern Black-capped Lory

Taxonomy. *Lorius hypoinchrous* G. R. Gray, 1859, Louisiade Archipelago = Sudest (Tagula) Island.

Genus name formerly given as *Domicella* Wagler, 1832, since *Lorius* Boddaert, 1783, applicable to *Eclectus*, had priority; however, Boddaert's name was officially suppressed in 1970, leaving *Lorius* Vigors, 1825, as the correct name for present species and congeners. Forms a superspecies with *L. garrulus*, *L. domicella* and *L. lory*. Proposed species "*L. amabilis*" (Stresemann's Lory) probably described from an aberrant individual of present species. Three subspecies recognized.

Subspecies and Distribution.

L. h. devittatus Hartert, 1898 - Bismarck Archipelago, SE New Guinea, Trobriand Is, D'Entrecasteaux Archipelago and Woodlark I.

L. h. hypoinchrous G. R. Gray, 1859 - Misima I and Tagula I (C Louisiade Archipelago).

L. h. rossellianus Rothschild & Hartert, 1918 - Rossel I (E Louisiade Archipelago).

Descriptive notes. 26-27 cm; 137-240 g. Similar to *L. lory somu* but with cere white, no black on belly, tail distally deep blue-green. Immature has brownish bill. Race *rossellianus* pinker red below, streaked violet; *devittatus* slightly larger, lacks black tips found on greater coverts of underwing in nominate.

Habitat. Coconuts apparently favoured, but also makes full use of original rain forest, mangroves, forest margins, tall secondary growth and partially cleared areas, up to 750 m in Bismarcks and up to 1600 m in D'Entrecasteaux Is. Where overlaps with *L. lory*, more a bird of coastal non-forest vegetation.

Food and Feeding. Fruit of the characteristic savanna tree *Antidesma gaisambulla*, flowers of *Plerandra*, blossoms or very tiny fruits of coconut trees.

Breeding. Reputedly mid-year, with nest placed high in huge tree.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Common to abundant throughout its range.

Bibliography. Beehler (1978a), Beehler *et al.* (1986), Bell (1970a, 1970d), Clapp (1987b), Coates (1985), Diamond (1972a), Eastwood (1995c), Finch & McKean (1987), Gilliard & LeCroy (1967a), Hartert (1926b), LeCroy & Peckover (1983), LeCroy *et al.* (1984), Mayr & Rand (1937), Mayr & Van Deusen (1956), Orenstein (1976), Peckover & Filewood (1976), Rand & Gilliard (1967).

26. White-naped Lory

Lorius albidinuchus

French: Lori à nuque blanche

German: Weißnacktenlori

Spanish: Lori Nuquiblanco

Taxonomy. *Domicella albidinucha* Rothschild and Hartert, 1924, hills on south-east coast of New Ireland.

Genus name formerly given as *Domicella* Wagler, 1832, since *Lorius* Boddaert, 1783, applicable to *Eclectus*, had priority; however, Boddaert's name was officially suppressed in 1970, leaving *Lorius* Vigors, 1825, as the correct name for present species and congeners. Monotypic.

Distribution. SE New Ireland.

Descriptive notes. 26-28 cm; 120-146 g. Mainly red, including underwing-coverts; bill reddish orange; crown above line through eye black, bordered by white inverted triangular nuchal patch; indistinct narrow yellow band across breast; wings green, with broad yellow band across underside of flight-feathers; tail broadly tipped dull green above, dusky yellow below. Immature undescribed.

Habitat. Forest from 500-2000 m.

Food and Feeding. Fruits and flowers of a wild oil palm; seen feeding acrobatically in understorey.

Breeding. No information available.

Movements. No information available.
Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife “restricted-range” species. Common locally throughout its altitudinal range.
Bibliography. Beehler (1978a), Coates (1985), Collar *et al.* (1994), Dahl (1986), Finch & McKean (1987).

27. Yellow-bibbed Lory

Lorius chlorocercus

French: Lori à collier jaune **German:** Grünschwanzlori **Spanish:** Lori Acollarado

Taxonomy. *Lorius chlorocercus* Gould, 1856, San Cristobal, Solomon Islands.
Genus name formerly given as *Domicella* Wagler, 1832, since *Lorius* Boddaert, 1783, applicable to *Eclectus*, had priority; however, Boddaert's name was officially suppressed in 1970, leaving *Lorius* Vigors, 1825, as the correct name for present species and congeners. Monotypic.
Distribution. E Solomon Is.
Descriptive notes. 28 cm; 153-225 g. Mainly red; bill orange; crown to nape above line through eye black; blackish markings on sides of neck linked by narrow yellow line across lower throat; wings green above with white at bend, below blackish with broad red patch across underside of

Status and Conservation. Not globally threatened. CITES II. A BirdLife “restricted-range” species. Generally fairly common, and the commonest large parrot on Guadalcanal and San Cristobal. A popular local cagebird and occasionally shot for food. Rare on Rennell.
Bibliography. Buckingham *et al.* (1995), Cain & Galbraith (1956), Dahl (1986), Harrison & Holyoak (1970), Mayr (1931, 1945b), Sweeney (1993b), Tiskens (1996).

primaries; underwing-coverts, flanks and thighs purplish blue; tail tipped green above, dusky yellow below. Immature lacks black and yellow on neck and throat.
Habitat. Canopy of primary forest, second growth and sometimes coconut plantations, at all altitudes; commoner in hills, especially mist forest, than lowlands, and in primary habitats than disturbed areas.
Food and Feeding. Pollen, nectar, fruits, small seeds and caterpillars recorded.
Breeding. No information except gonads undeveloped in Jun, Jul and Nov.
Movements. No information.

PLATE 31

inches 3
cm 8

Genus *PHIGYS* G. R. Gray, 1870

28. Collared Lory

Phigys solitarius

French: Lori des Fidji **German:** Einsiedlerlori **Spanish:** Lori Solitario
Other common names: Collared Lorikeet, Solitary Lory/Lorikeet

Taxonomy. *Psittacus solitarius* Suckow, 1800, Fiji Islands.

Genus is osteologically very similar to *Vini* and may not merit recognition. Monotypic.

Distribution. Fiji, occurring on the larger islands and on Makogai in Lomaiviti group.

Descriptive notes. 20 cm; 71–92 g. Bill orange; crown above line through eye glossy purplish black, bordered on nape by elongated bright yellowish green feathers; back, wings and tail green; face below eye, upper back and undersides down to mid-belly red; lower belly blackish purple, green on vent and undertail-coverts; legs orange. Female has paler, bluish fore-crown, more green on collar. Immature duller green and non-elongate on nape, with darker bill and legs.

Habitat. Forested areas up to 1200 m or more, being plentiful in wetter windward areas, less so in leeward coastal farmlands; also plantations and tree-lined streets in villages and towns.

Food and Feeding. Blossoms of coconut palms, *Erythrina indica* and *Spathodea campanulata*; also fruits of cultivated mango (*Mangifera indica*) and soursop (*Annona muricata*).

Breeding. Jul, Nov–Dec. Nest in hole in tree or stump, sometimes in rotting coconut still attached to tree. Eggs 2; in captivity, incubation c. 30 days, nestling period c. 9 weeks.

Movements. Seasonal movements reported in some areas, in response to annual availability of food, e.g. birds move into the Sigatoka valley, Viti Levu, when *Erythrina* trees bloom in Aug–Sept.

Status and Conservation. Not globally threatened. CITES II. A BirdLife “restricted-range” species. Common in forests and wetter areas on Viti Levu and Vanua Levu; also common on 10 km² Makogai I; rare on Ngau possibly owing to nest-site competition from the common *Prosopaea tabuensis*.

Bibliography. Bahr (1912), Clunie (1984), Courtney (1997b), Dahl (1986), Gorman (1972, 1975), Holyoak (1979), Lever (1987), Low (1994b), Mayr (1945b), Patten (1941), Pratt *et al.* (1987), Schroeder (1993), Steadman & Zariello (1987), Watling (1982a, 1982b, 1985).

Genus *VINI* Lesson, 1831

29. Blue-crowned Lorikeet

Vini australis

French: Lori fringillaire **German:** Blaukäppchen **Spanish:** Lori de Samoa
Other common names: Blue-crowned Lory

Taxonomy. *Psittacus australis* J. F. Gmelin, 1788, Sandwich Islands; error = Samoa Islands.

Monotypic.

Distribution. Lau Archipelago (E Fiji), Futuna and Wallis Is to Samoa and Tonga and on to Niue.

Descriptive notes. 19 cm; 47–52 g. Orange bill, grass green forehead backed by pale bright purplish blue mid- to hindcrown with slightly elongate feathers; patch from lores and below eye to upper breast red; rest of body green except for a red belly patch that shades purple between and onto thighs, underside of tail yellowish, legs orange. Immature has less colour on undersides.

Habitat. Forest, scrub, gardens and plantations, wherever flowering trees are present; commoner or more easily detected in cultivated areas than in forest, but much rarer in cleared forest or urban land.

Food and Feeding. Nectar, pollen and soft fruit, with a preference for coconut, mango, *Erythrina*, *Elaeocarpus angustifolius* and *Calophyllum inophyllum*. However, on Niuafo’ou flowering *Casuarina* is a key food source, others being *Sterculia fanaiho*, *Kleinhovia hospita*, *Musa paradisiaca*, *Alphitonia ziziphoides*, *Pueraria lobata*, *Barringtonia asiatica*, *Hibiscus tiliaceus* and *Pometia pinnata*; elsewhere flowers of thatching palm *Metroxylon* noted. Use of unripe mangoes and flowers of a woody weed *Stachytarpheta urticifolia* was probably the result of food shortage following a hurricane.

Breeding. Possibly throughout year as records are for Mar, Jun, Aug & Dec (nestlings). Nest a hole in a tree, once a *Hibiscus*; records of using holes in earth banks probably involved takeovers of old kingfisher nests. Eggs 1–2; incubation in captivity 23 days.

Movements. Birds are highly mobile, moving about within islands in search of foods as they become available, and apparently a well-known inter-island nomad.

Status and Conservation. Not globally threatened. CITES II. A BirdLife “restricted-range” species. Common throughout much of range, including Lau Archipelago, Samoa and Futuna, with numbers estimated between several 100’s and several 1000’s; but on Wallis, extinct for unknown reasons, though probably due to black rats (*Rattus rattus*). Declining in Tonga, but abundant on Niuafo’ou (several thousand pairs) and, by 1974 report, Niuaotuputu, while uncommon on Late, probably owing to scarcity of flowering trees. A population of around 60 survives on ‘Eue’iki in the Tongatapu group, 1990, where isolated for probably 100 years. The extinction of the species on ‘Eua occurred within 50 years of the island’s colonization by *R. rattus*. The steady spread of the Jungle Myna (*Acridotheres fuscus*) through the Fijian, Tongan and Samoan archipelagos is viewed with concern, given its aggressive ability to compete for nest-holes.

Bibliography. Amerson *et al.* (1982), Armstrong (1932), Banks (1984), Campbell (1993), Clunie (1984), Courtney (1997b), Dhondt (1976), Engbring & Ramsey (1989), Evans, S.M. *et al.* (1992), Gill (1995), Guyot & Thibault (1987, 1988), Hay (1986), Low (1994b), Mayr (1945b), Muse & Muse (1982), Pratt *et al.* (1987), Reed (1980b), Rinke (1985, 1986a, 1986b, 1991), Rinke *et al.* (1992), Watling (1982a).

30. Rimatara Lorikeet

Vini kuhlii

French: Lori de Kuhl **German:** Rubinlori **Spanish:** Lori de Rimatara
Other common names: Scarlet-breasted/Kuhl’s/Ruby Lorikeet/Lory

Taxonomy. *Psittacula Kuhlhi* Vigors, 1824, Toohooteterooha Island, a day’s sail from Otaheite. Monotypic.

Distribution. Rimatara in Cook Is: Kiritimati (Christmas), Tabuaeran (Fanning) and Teraina (Washington) in N Line Is. Kiribati.

Descriptive notes. 19 cm. Bill orange; crown above line through eye green and nape purplish blue, all with slightly elongate feathers; underparts red; thighs purple; mantle green shading darker on wings and to yellowish on back, rump, upper- and undertail-coverts and vent; tail above dark reddish centrally with dark outer feathers, greyish below; legs orange-brown. Immature barred purple below, less red in tail.

Habitat. On Rimatara birds appear to favour the mixed horticultural belt (61% of the population in 32% of its available area), being uncommon in coastal coconut plantations and rare in makatea forest. On Teraina birds use all terrestrial habitats including coconut-dominated forest, stands of *Pisonia grandis*, *Pandanus* areas and a coastal fringe of *Messerschmidia argentea*, *Scaevola taccada* and *Cordia subcordata*.

Food and Feeding. On Rimatara 12 recorded foodplants (flowers) in Aug, in descending order of importance, were: *Inga ynga*, *Casuarina equisetifolia* (seeds), *Paraserianthes falcata*, *Musa*, *Mangifera*, *Ceiba pentandra*, *Cocos nucifera*, *Hibiscus rosa-sinensis*, *Erythrina variegata*, *Adenanthera pavonina*, *Syzygium jambos*, *Albizia lebbek*; at other seasons flowers of *Coffea arabica* and *Hibiscus tiliaceus* and rotting leaf borders of *Barringtonia asiatica*. On Teraina *Terminalia catappa* and *Premna obtusifolia* noted.

Breeding. Jan–Apr. Nests in coconut palms, once reportedly in the rotten trunk of a *Pandanus*. In captivity: 2 eggs; nestling period c. 7 weeks.

Movements. Sedentary.

Status and Conservation. ENDANGERED. CITES II. A BirdLife “restricted-range” species. This species was almost certainly introduced to Tabuaeran and Teraina, and is known to have been to Kiritimati. It is not common on Rimatara, its one remaining native island, with a total population of 900 estimated in Aug 1992. Fewer than 50 were judged present on Tabuaeran in Feb 1993, apparently having declined in response to colonization by the black rat *Rattus rattus*. On Teraina 1000–1600 birds were estimated present in Feb 1993. On Kiritimati a few birds survive from several small releases since 1959, but conditions on the island are unfavourable. Extinction on other islands in the Cooks appears to be the result of over-exploitation for use of feathers by native peoples. Introduction to ‘Atiu, free of black rats, should be undertaken. There is a clear need for greater awareness of the international significance of Teraina’s population. Keeping black rats off both Rimatara and Teraina is essential.

Bibliography. Bruner (1972), Collar & Andrew (1988), Collar *et al.* (1994), Gallagher (1960), Garnett (1983), Hay (1986), Holyoak & Thibault (1984), King (1973), Kirby (1925), Lee (1935), Lever (1987), Low (1994b), McCormack (1997), McCormack & Künzle (1996), Patten (1947), Pratt *et al.* (1987), Seitre, J. & Seitre (1991), Seitre, R. & Seitre (1992), Steadman (1985), Thibault (1973b), Watling (1995).

31. Henderson Lorikeet

Vini stepheni

French: Lori de Stephen **German:** Hendersonlori **Spanish:** Lori de Stephen
Other common names: Stephen’s Lorikeet/Lory

Taxonomy. *Calliptilus ? stepheni* North, 1908, Henderson Island. Monotypic.

Distribution. Henderson I, in the Pitcairn Group.

Descriptive notes. 19 cm; 42–55 g. Similar to *V. kuhlii* but lacks purplish blue nape and has broken green breastband, less bright rump and longer, wedge-shaped all-yellowish tail. Immature has mostly green underparts.

Habitat. Native forest, which covers the island.

Food and Feeding. A variety of food types, including nectar, pollen, fruit and insect larvae, from canopy level in coconut palms to ground-level shrubs, species involved being: nectar and/or pollen

On following pages: 32. Blue Lorikeet (*Vini peruviana*); 33. Ultramarine Lorikeet (*Vini ultramarina*); 34. Musk Lorikeet (*Glossopsitta concinna*); 35. Little Lorikeet (*Glossopsitta pusilla*); 36. Purple-crowned Lorikeet (*Glossopsitta porphyrocephala*); 37. Palm Lorikeet (*Charmosyna palmarum*); 38. Red-chinned Lorikeet (*Charmosyna rubrigularis*); 39. Meek’s Lorikeet (*Charmosyna meeki*); 40. Blue-fronted Lorikeet (*Charmosyna toxopei*); 41. Striated Lorikeet (*Charmosyna multistriata*); 42. Pygmy Lorikeet (*Charmosyna wilhelminae*); 43. Red-fronted Lorikeet (*Charmosyna rubronotata*); 44. Red-flanked Lorikeet (*Charmosyna placentis*); 45. New Caledonian Lorikeet (*Charmosyna diadema*); 46. Red-throated Lorikeet (*Charmosyna amabilis*).

Status and Conservation. VULNERABLE. CITES II. A BirdLife "restricted-range" species. Numbers were estimated in 1987 at 720-1820 birds and in 1992 at 2400 birds. Population essentially secure so long as no settlement of its 37 km² sole home is attempted, bringing with it the increased chance of colonization by black rats *Rattus rattus*; one such attempt was headed off in 1983.

Bibliography. Amadon (1942), Benton & Spencer (1995), Bourne & David (1983), Collar & Andrew (1988), Collar *et al.* (1994), Dahl (1986), Fosberg *et al.* (1983), Graves (1992), Holyoak & Thibault (1984), Pratt *et al.* (1987), Serpell *et al.* (1983), Trevelyan (1995), Williams (1960).

32. Blue Lorikeet

Vini peruviana

French: Lori nonnette **German:** Saphirlori

Spanish: Lori Monjita

Other common names: Tahitian Lorikeet/Lory

Taxonomy. *Psittacus peruvianus* P. L. S. Müller, 1776, Peru; error = Tahiti. Monotypic.

Distribution. Aitutaki in Cook Is; Motu One and Manuae in Society Is; and Rangiroa, Arutua, Apataki and Tikehau in Tuamotu Archipelago.

Descriptive notes. 18 cm; 31-34 g. Orange bill and legs, white from line through eye to ear-coverts down to breast, otherwise deep purplish blue, with feathers of crown somewhat elongate. Immature below greyish blue with whitish markings on chin, bill black.

Habitat. Birds occupy any wooded habitats, with a possible preference, perhaps only seasonal, for coconut and banana plantations, but mixed stands of native and cultivated trees seem generally favoured. On low sandy islets (*motus*) of atolls, found in flowering plants, e.g. *Scaevola*.

Food and Feeding. Flowers, and/or their products, of coconut, banana, hibiscus, mango and

Tournefortia, leaf shoots of mango, fruit of *Morinda citrifolia* and banana.

Breeding. May-Jul claimed, but Oct and Dec-Jan recorded. An Aitutaki nest was 11 m up in hole at base of broken branch of Java plum (*Syzygium cumini*); one on Manuae was in a hole high in a dead *Pandanus*. Eggs 2; incubation in captivity 25 days, nestling period c. 60 days.

Movements. Occupation of areas may be related to food availability; few birds were present in S of Aitutaki, Feb 1991, but birds were common there in Oct 1995.

Status and Conservation. VULNERABLE. CITES II. A BirdLife "restricted-range" species. Extinctions have occurred on many islands within this species's range, only partly compensated by one spectacular introduction (to Aitutaki). Populations judged as follows: Motu One 500 birds, Manuae 600-800, Rangiroa possibly several hundred, Arutua unknown, Apataki at least 300 on one *motu*, Tikehau 60, Aitutaki c. 1200. Survival of this species is related to the absence of black rats (*Rattus rattus*), and conservation awareness relating to the prevention of the introduction of this animal is essential. Also important will be the checking of some still unexplored islands in case they hold populations, and the translocation of birds to rat-free islands. Although trade is illegal, birds are still captured and sold on Rangiroa.

Bibliography. Amadon (1942), Bruner (1972), Child (1981), Collar & Andrew (1988), Collar *et al.* (1994), Courtney (1997b), Gill (1996), Harrison & Holyoak (1970), Hay (1986), Holyoak (1973b, 1974b, 1980), Holyoak & Thibault (1984), King (1978/79), Lever (1987), Low (1985, 1994b), McCormack (1997), Poulsen *et al.* (1985), Pratt *et al.* (1987), Seitre, J. & Seitre (1991), Seitre, R. & Seitre (1992), Taylor (1984), Thibault, B. & Thibault (1973), Thibault, J.C. (1974, 1988), Voisin *et al.* (1996), Wilson, K.J. (1993), Yealland (1940).

33. Ultramarine Lorikeet

Vini ultramarina

French: Lori ultramarin **German:** Ultramarinlori

Spanish: Lori Ultramar

Other common names: Ultramarine Lory

Taxonomy. *Psittacus ultramarinus* Kuhl, 1820, New Holland?; error = Marquesas Islands. Monotypic.

Distribution. Ua Pou and Ua Huka, and possibly still Nuku Hiva, in Marquesas Is, with a small new population on Fatu Hiva. Pre-historically on Ua Huka and Tahuata.

Descriptive notes. 18 cm. Bill orange; forehead cobalt blue, rest of crown purple-blue with slightly elongate feathers; rest of upperparts dull, slightly turquoise blue, increasingly pale through rump to tail which shades white at tip; front of face white, chin, ear-coverts, throat and breast mottled white and dark purple; belly purple, with extensive white lower flank patches; legs dull orange. Immature mostly lacks breast mottling.

Habitat. Wooded vegetation wherever flowering trees occur, from native forest in hills to coconut plantations and *Erythrina* trees near coasts.

Food and Feeding. Flowers, and/or their products, of coconut and banana, buds, fruits of breadfruit (*Artocarpus altilis*) and mango (*Mangifera indica*), and hemipteran adults and grubs.

Breeding. Reportedly Jun-Aug, but bird in breeding condition in Sept. Nest in hollow in tree, a still-hanging old coconut, or old nests made by finches and other birds. In captivity: 2 eggs; nestling period c. 8 weeks.

Movements. Sedentary.

Status and Conservation. ENDANGERED. CITES II. A BirdLife "restricted-range" species. Almost certainly black rats (*Rattus rattus*) are responsible for the decline of this species, which was formerly widespread. It declined from 500-600 birds on Ua Pou in 1975 to be rare by 1990, probably owing to the advent of rats around 1980. On Nuku Hiva an estimated 70 birds in 1975 declined possibly to extinction by 1990. On Ua Huka the species was introduced or reintroduced around 1940, and by 1991 some 1000-1500 birds were present. In attempt to establish viable population on another less disturbed island of former range, total of 29 birds relocated on Fatu Hiva in period 1992-1994; subsequent survey work indicates birds surviving and possibly breeding, with intensive survey planned for 1997.

Bibliography. Anon. (1997d), Collar & Andrew (1988), Collar *et al.* (1994), Harrison & Holyoak (1970), Hay (1986), Holyoak (1975), Holyoak & Thibault (1984), King (1978/79), Kuehler & Lieberman (1993a, 1993b), Kuehler *et al.* (1997), Lever (1987), Lieberman *et al.* (1997), Low (1994b), Montgomery *et al.* (1980), Pratt *et al.* (1987), Seitre, J. & Seitre (1991), Seitre, R. & Seitre (1992), Steadman (1989a), Steadman & Zarriello (1987), Tavistock (1939), Thibault, B. & Thibault (1973), Thibault, J.C. (1973a, 1988).

Genus GLOSSOPSITTA Bonaparte, 1854

34. Musk Lorikeet

Glossopsitta concinna

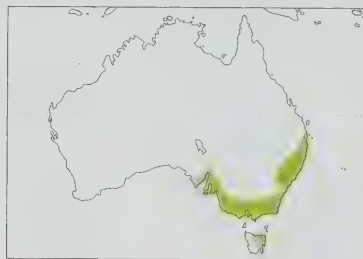

French: Lori à bandeau rouge

German: Moschuslori

Spanish: Lori Almiclero

Taxonomy. *Psittacus concinnus* Shaw, 1791, New South Wales. Monotypic.

Distribution. E & SE Australia, Kangaroo I and Tasmania.

Descriptive notes. 22 cm; 52-65 g. Bill blackish tipped orange; forecrown and ear-coverts red, with light blue streaking below eye; mid-crown dull blue shading to green on hindcrown and to olive-yellow on nape and mantle; back and wings green; tail green, with basal red on underside of lateral feathers; underparts and underwing-coverts yellowish green, yellow along upper flanks; legs greyish. Female has less extensive blue on crown. Immature duller, with dull red head markings.

Habitat. Wooded country, preferring more open habitats such as eucalypt woodland, riparian growth and farmland groves, penetrat-

ing suburban areas and parks.

Food and Feeding. Nectar, pollen and blossoms, especially of eucalypts, flowers, young shoots and buds of *Callistemon citrinus*, *Grevillea robusta* and *Angophora*; also berries, fruits, seeds and insects, sometimes becoming a pest in orchards and on maize and sorghum crops.

Breeding. Aug-Jan. Nest in hollow limb or hole in tree, usually high in a living eucalypt near water. Eggs usually only 2; in captivity, incubation 21-22 days (28-30 days also recorded), nestling period 45-50 days.

Movements. Nomadic. Birds move about in response to flowering of trees, but apparently in a more predictable pattern than other lorikeets, birds tending to visit a particular area at regular intervals over a number of years. However, in some fruit-growing areas of Tasmania the birds' presence is difficult to predict, with large flocks often forming.

Status and Conservation. Not globally threatened. CITES II. Very common throughout mainland Australian range except in alpine region.

Bibliography. Blakers *et al.* (1984), Courtney (1997b), Emison *et al.* (1987), Forshaw (1981b), Lea & Gray (1935), Lindsey, T.R. (1992), Macdonald (1988), McCulloch (1981), Pizzey & Doyle (1980), Rose (1997b), Schodde & Tidemann (1986), Simpson & Day (1996), Traill *et al.* (1996), Trounson & Trounson (1987), Wilkinson *et al.* (1993), Wood, K.A. (1992).

35. Little Lorikeet

Glossopsitta pusilla

French: Lori à masque rouge

German: Zwergmoschuslori

Spanish: Lori Carirrojo

Taxonomy. *Psittacus Pusillus* Shaw, 1790, New South Wales.

Forms a parapatric species pair with *G. porphyrocephala*. Monotypic.

Distribution. E & SE Australia; also reported to occur in Tasmania.

Descriptive notes. 15 cm; 34-53 g. Generally green, more yellowish below; black bill; front of head around bill, from forehead through eye to chin, red; pale green streaking on ear-coverts; light bronze tinge to nape and mantle; tail below red basally, shading to yellow with grey tips. Immature has duller red face.

Habitat. Canopy of trees in open wooded country, particularly in riparian stands of *E. camaldulensis* and associated box-ironbark forests, but possibly also in denser forest, where less easily detected; occurs at all altitudes within range.

Food and Feeding. Pollen, nectar, blossoms of *Eucalyptus* (in winter *E. sideroxylon* and *E. leucoxylon*), *Melaleuca* and *Xanthorrhoea* trees,

flowers and juice of mistletoe *Amyema cambagei* and *A. gaudichaudi*, berries of *Loranthus* and fruit of *Eriobotrya japonica*; birds visit orchards but are not serious pests.

Breeding. Jun-Jan, as early as May in N. Nest in hollow limb or hole in tree, usually a living eucalypt near water, 7-12 m up. Eggs 3-5; in captivity, incubation lasts 22 days, nestling period c. 6 weeks.

Movements. Nomadic, following flowering events in different areas.

Status and Conservation. Not globally threatened. CITES II. Common to abundant in centre of range in S Queensland and New South Wales, becoming moderately common to uncommon at the extremities. Of several records from Tasmania only one involved positive identification, and there is no recent evidence.

Bibliography. Barnicoat (1976), Blakers *et al.* (1984), Courtney (1997b), Emison *et al.* (1987), Forshaw (1981b), Haines (1946), Lendon (1951), Lindsey, T.R. (1992), Macdonald (1988), Pizzey & Doyle (1980), Schodde & Tidemann (1986), Simpson & Day (1996), Troupson & Troupson (1987).

36. Purple-crowned Lorikeet

Glossopsitta porphyrocephala

French: Lori à couronne pourpre **German:** Blauscheitellori **Spanish:** Lori Coronipúrpura

Taxonomy. *Trichoglossus porphyrocephalus* Dietrichsen, 1837, South Australia.

Forms a parapatric species pair with *G. pusilla*. Monotypic.

Distribution. SW & SE Australia including Kangaroo I. with vagrant flocks recorded as far N as SE Queensland.

Descriptive notes. 15 cm; 37-50 g. Bill black; frontal band and lores fiery red; crown deep purple; upper cheek to nape light green, except ear-coverts orange-yellow; chin and lower cheek to mid-belly pale blue, shading on flanks, thighs and lower belly to light green; mantle stained olive brown; rest of upperparts rich green; leading edge of wing blue; underwing-coverts red, underside of flight-feathers brown. Immature has reduced head colour.

Habitat. Lightly wooded inland country, notably dry mallee areas and open savanna, but also heavy *Eucalyptus* forest and coastal scrublands, often plentiful in suburbs.

Food and Feeding. Nectar and pollen from blossoms of various *Eucalyptus* (at least 13 species identified), *Melaleuca* and *Myoporum insulare* trees, sometimes moving to heathland for *Banksia* flowers in winter; fruits may also be taken, and the species may cause damage in orchards.

Breeding. Aug-Dec. Nest in hollow limb or hole in tree, usually a living or dead eucalypt near water. Often loosely colonial. Eggs 3-4; in captivity, incubation 22 days, nestling period c. 6 weeks.

Movements. Partly nomadic, some birds seemingly sedentary but others forming large flocks, and in Victoria (except extreme W) its presence in any area being related to the flowering of eucalypts. Birds regularly penetrate far SW New South Wales, and vagrants have reached SE Queensland.

Status and Conservation. Not globally threatened. CITES II. Common in most of range, becoming less frequent in Victoria; however, a substantial chronic decline in numbers documented in SW Australia.

Bibliography. Blakers *et al.* (1984), Carter (1923), Churchill & Christensen (1970), Emison *et al.* (1987), Forshaw (1981b), Hopper (1980), Hopper & Burbidge (1979), Lindsey, T.R. (1992), Macdonald (1988), Masters & Milhinch (1974), Pizzey & Doyle (1980), Richardson & Wooller (1990), Saunders & Ingram (1995), Schodde & Tidemann (1986), Simpson & Day (1996), Troupson & Troupson (1987), Wooller *et al.* (1988).

Genus CHARMOSYNA Wagler, 1832

37. Palm Lorikeet

Charmosyna palmarum

French: Lori des palmiers **German:** Palmenlori **Spanish:** Lori Palmero

Taxonomy. *Psittacus palmarum* J. F. Gmelin, 1788, Tanna Island.

Monotypic.

Distribution. Vanuatu, Banks Is, Santa Cruz Is and Duff Is.

Descriptive notes. 15-17 cm. Green, with rather small red patch around bill from lores to chin; mantle washed pale brown; underwing-coverts greyish green; tail tipped yellow; bill and legs orange. Female has red reduced or lacking, no brown. Immature like female.

Habitat. Montane and lowland forest, but seemingly intolerant of disturbed areas at lower levels.

Food and Feeding. Nectar and pollen of various trees, palms, lianas and shrubs, notably from flowers of sago palms (*Metroxylon rumphii*) and *Erythrina*; also takes fruit of figs (*Ficus*) and berries.

Breeding. One nest on Vanuatu in Dec, was in hollow limb of tree c. 6 m up, in cloud forest (at 1600 m), with two half-grown young.

Movements. Apparently nomadic, travelling widely between feeding areas and appearing unpredictably in coastal areas, sometimes in large numbers.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. Commoner in hills above 1000 m than in lowlands.

Bibliography. Amadon (1942), Bregulla (1992), Collar *et al.* (1994), Diamond (1975b), Diamond & Marshall (1976), Mayr (1945b), Parker (1968).

38. Red-chinned Lorikeet

Charmosyna rubrigularis

French: Lori à menton rouge **German:** Rotkinnlori **Spanish:** Lori Barbirrojo

Taxonomy. *Trichoglossus rubrigularis* P. L. Sclater, 1881, New Britain.

Monotypic.

Distribution. New Britain and New Ireland, and also Karkar I off NE coast of New Guinea.

Descriptive notes. 17 cm; 31-40 g. Green, brighter below, with reddish orange bill and red chin, orange-red legs; ear-coverts slightly bluish with pale green streaks; underside of flight-feathers greyish brown with broad yellow mid-stripe; underside of tail greyish brown but red basally and broadly tipped yellow. Immature has less red on chin, shorter tail.

Habitat. Canopy of hill and montane forest above 500 m, although generally much commoner from 1000-1500 m, and on Karkar rare below 2000 m.

Food and Feeding. Noted feeding on inflorescences of a native palm; paste in stomachs ap-

parently composed of nectar and macerated flowers.

Breeding. No clear information; evidence from Karkar suggests no activity May-Jun.

Movements. Apparently sedentary.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Common to abundant.

Bibliography. Beehler (1978a), Beehler *et al.* (1986), Coates (1985), Diamond & LeCroy (1979), Eastwood (1995c), Finch (1981), Finch & McKean (1987), Gilliard & LeCroy (1967a), Greensmith (1975), Rand & Gilliard (1967).

39. Meek's Lorikeet

Charmosyna meeki

French: Lori de Meek **German:** Salomonenlori **Spanish:** Lori de Meek

Taxonomy. *Hypocharmosyna meeki* Rothschild and Hartert, 1901, Kolombangara, Solomon Islands.

Monotypic.

Distribution. Elevated Solomon Is, including Bougainville.

Descriptive notes. 16 cm; 21-32 g. Green, bright below, duller olive on wings and tail; bill and legs orange; crown faintly tinged greyish; ear-coverts and sides of neck show light green streaking on dark; mantle tinged brown; yellowish white band on underside of secondaries; tail yellow below. Immature has shorter tail, paler bill with brownish markings near base.

Habitat. Canopy of foothill and montane mist forest, 300-1500 m, even extending into stunted cloud forest at 1700 m; on Santa Isabel present at 900-1000 m, on Kolombangara only common from 1300 m, and on Guadalcanal not

found below 1000 m. Birds on Kolombangara observed to move downslope in day to forage, sometimes to coast.

Food and Feeding. Blossoms of *Syzygium*, *Metrosideros*, *Mearnsia* and coconuts recorded; also soft fruit and berries.

Breeding. Only nest known, containing small young, was in a large clump of moss on tree trunk 6 m above ground in stunted moss forest at 1550 m on Kolombangara, in Aug.

Movements. Described as rather nomadic on Bougainville; possibly so at higher altitudes on all islands.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. On summit of Kolombangara, one of three most abundant bird species. Although generally in small parties, birds congregate in larger numbers at blossoming trees.

Bibliography. Buckingham *et al.* (1995), Cain & Galbraith (1956), Coates (1985), Dahl (1986), Hadden (1981), Mayr (1945b), Schodde (1977), Webb (1992).

40. Blue-fronted Lorikeet

Charmosyna toxopei

French: Lori de Buru **German:** Burulori **Spanish:** Lori de Buru

Other common names: Buru Lorikeet

Taxonomy. *Hypocharmosyna toxopei* Siebers, 1930, Buru.

Monotypic.

Distribution. Buru in S Moluccas.

Descriptive notes. 16 cm. Green above, yellowish green on breast; bill and legs orange; forehead green, forecrown pale blue; yellow band across underside of secondaries; underside of tail yellowish, red basally. Female has reduced blue on crown, stronger band on secondaries. Immature darker and duller.

Habitat. Probably the canopy of montane forest, the type series coming from 850-1000 m; however, it may in fact be a lowland forest bird.

Food and Feeding. Unrecorded but certainly nectar and pollen.

Breeding. No information.

Movements. No information.

Status and Conservation. **VULNERABLE.** CITES II. A BirdLife "restricted-range" species. Extremely poorly known. Originally described from snared birds brought to camp, the species has not certainly been recorded since: observations in 1980 suggesting the species was fairly common have been ascribed instead to *C. placensis*, although it now appears that the latter does not occur on Buru. Four lorikeets seen in 1989 could not be unequivocally identified, but were probably *toxopei*. If it is a lowland or nomadic bird it could be highly threatened by deforestation.

Bibliography. Andrew (1992), Anon. (1996e), Coates & Bishop (1997), Collar & Andrew (1988), Collar *et al.* (1994), Jepson (1993), Marsden *et al.* (1997), Poulsen & Purniassa (1996), Robson (1990a), Siebers (1930), Smiet (1985), Sujatnika & Jepson (1995), Sujatnika *et al.* (1995), Wheatley (1996), White & Bruce (1986).

41. Striated Lorikeet

Charmosyna multistriata

French: Lori strié

German: Streifenlori

Spanish: Lori Estriado

Other common names: Streaked/Yellow-streaked Lorikeet

Taxonomy. *Charmosynopsis multistriata* Rothschild, 1911, upper Setekwa River, New Guinea. Monotypic.

Distribution. C New Guinea on S slope of Central Ranges, from Snow Mts E into Chimbu Province.

Descriptive notes. 18 cm. Green, darker and plain above, paler and with fine yellow streaking below, this being lighter and somewhat whiter on face, becoming heavier and yellower on breast to belly; small vent patch red; hindcrown mid-brown with paler and darker flecks; eye red to brown, bill bluish above, yellowish orange below and on tip; legs grey. Immature has darker head, duller streaking.

Habitat. Foothill and lower montane forest, from lowlands at 80 m up to 1800 m.

Food and Feeding. Flowers of canopy trees and epiphytes, including inflorescences of *Dimorphanthera* and *Poikilospermum*.

Breeding. No information.

Movements. Possibly nomadic: birds in E of range appeared in mixed nectarivore flocks at peak of flowering usually Mar-Jul.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. Little known and poorly recorded but, although described as rare, evidently still secure. Fairly common in Ok Tedi area in WC Papua New Guinea.

Bibliography. Andrew (1992), Anon. (1994a, 1994b), Beehler *et al.* (1986), Coates (1985), Coates & Lindgren (1978), Collar *et al.* (1994), Gregory (1995a, 1995b), Mack & Wright (1996), Paulik & Kruszona (1991), Rand (1938, 1942a), Rand & Gilliard (1967), Sujatnika *et al.* (1995).

42. Pygmy Lorikeet

Charmosyna wilhelminae

French: Lori de Wilhelmina

German: Elfenlori

Spanish: Lori Pigmeo

Other common names: Wilhelmina's/Pygmy Streaked Lorikeet

Taxonomy. *Trichoglossus wilhelminae* A. B. Meyer, 1874, west coast of Geelvink Bay. Monotypic.

Distribution. W, C & E New Guinea from Vogelkop E to Owen Stanley Range.

Descriptive notes. 13 cm. Green above, yellowish green below; mid- to hindcrown purple with blue streaks; hindneck stained brownish; thin yellow streaks on breast; underwing-coverts and broad band on underside of flight-feathers red; lower back red, rump cobalt; underside of tail red basally; bill yellowish orange; legs grey. Female lacks red on rump. Immature lacks crown and breast streaks.

Habitat. Canopy of mountain forest and edges, moss forest, adjacent savanna woodlands, generally 1000-2200 m although often lower.

Food and Feeding. Pollen and nectar; re-

corded trees include eucalypts and *Castanopsis* oaks, and inflorescences of *Elaeocarpus*.

Breeding. No information.

Movements. Appears to show some nomadism in response to flowering of certain trees, and regular appearance in the period May-Nov occurs at 220 m near Port Moresby. In one upland area, only recorded at peak flowering times.

Status and Conservation. Not globally threatened. CITES II. Generally uncommon but easily overlooked; usually singly or in pairs.

Bibliography. Andrew (1992), Anon. (1994a), Beehler (1978b), Beehler, Burg *et al.* (1994), Beehler, Pratt & Zimmerman (1986), Clapp (1979a), Coates (1985), Diamond (1972a), Gregory (1995a, 1995b), Mayr & Rand (1937), Rand & Gilliard (1967).

43. Red-fronted Lorikeet

Charmosyna rubronotata

French: Lori à front rouge

German: Rotstirnlori

Spanish: Lori Frentirrojo

Other common names: Red-spotted/Red-fronted Blue-eared Lorikeet

Taxonomy. *Coriphilus rubronotatus* Wallace, 1862, Salawati and the north-western extremity of New Guinea.

Two subspecies recognized.

Subspecies and Distribution.

C. r. rubronotata (Wallace, 1862) - Salawati I and N New Guinea from Vogelkop to Adelbert Mts.
C. r. kordoana (A. B. Meyer, 1874) - Biak I.

Descriptive notes. 17 cm; 30-35 g. Green above, yellowish green below; forehead and sides of breast red, as are underwing-coverts, uppertail-coverts and base of underside of tail; ear-coverts violet streaked blue; flanks and variable band across underside of secondaries yellow; underside of tail dusky yellowish; bill and legs reddish. Female lacks red on forehead, breast and underwing-coverts; ear-coverts green streaked yellow. Immature undescribed. Race *kordoana* has more, paler red on crown, bluer ear-coverts.

Habitat. Canopy of secondary forest and coconut plantations along the coastline and inland hill forest up to 900 m, being confined to mid-montane forest where lowlands occupied by *C. placensis*.

Food and Feeding. No certain information, but feeding in tall flowering trees observed and reportedly at coconut blossoms.

Breeding. No information.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Common in places, but generally not as abundant as sympatric congeners.

Bibliography. Andrew (1992), Beehler *et al.* (1986), Buckell (1994), Coates (1985), Cooke (1991b, 1993), Greensmith (1975), Mayr & Meyer de Schauensee (1939a), Pearson (1975b), Rand & Gilliard (1967), Ripley (1964), Sweeney (1997c).

44. Red-flanked Lorikeet

Charmosyna placensis

French: Lori coquet

German: Schönlori

Spanish: Lori Flanquirojo

Other common names: Blue-eared/Yellow-fronted/Yellow-fronted Blue-eared/Lowland Lorikeet

Taxonomy. *Psittacus placensis* Temminck, 1834, Utanata River, New Guinea.

Proposed race *occidentalis* included in nominate. Five subspecies recognized.

Subspecies and Distribution.

C. p. intensior (Kinnear, 1928) - N Moluccas and Gebe (W Papuan Is).

C. p. placensis (Temminck, 1834) - S Moluccas and Aru Is, and through S New Guinea to Gulf of Papua.

C. p. ornata Mayr, 1940 - W Papuan Is except Gebe, and N side of W Irian Jaya.

C. p. subplacensis (P. L. Slater, 1876) - NC New Guinea eastwards.

C. p. pallidior (Rothschild & Hartert, 1905) - Bismarck Archipelago to Bougainville.

Descriptive notes. 15-17 cm; 25-48 g. Generally green, yellowish on forehead; facial patch red, ear-coverts blue, sides of breast, flanks and underwing-coverts red, with yellow band across underside of flight-feathers; rump patch dark blue; tail green above, broadly tipped yellow and with subterminal red area in centre, yellow below; bill red, legs orange-red. Female lacks red and blue, and has ear-coverts bluish black streaked yellow, and green forehead. Immature like female, but male has some red. Race *intensior* slightly larger, darker blue on rump; *ornata* has more extensive red on throat, and is slightly darker green, with larger blue rump;

subplacensis without blue rump; *pallidior* like previous race but paler and perhaps brighter.

Habitat. Forest, especially mangroves; also savanna woodland, tall secondary growth, coastal *Casuarina* groves, coconut and sago plantations, riverside palm and eucalypts, and open cultivated areas. Generally reported from lowlands, below 250 m in Halmahera and Kai Is, with some records up to 1400 m; however, recently found up to 800 m on Halmahera, with highest densities above 700 m.

Food and Feeding. Apparently mainly or exclusively flowers and their nectar and pollen, including *Erythrina indica*, *Schefflera*, *Syzygium*, *Melicope*, *Poikilospermum*, *Dimorphanthera* and *Cocos nucifera*. One observation of birds apparently ingesting lichen and moss off trunks, branches and epiphytes.

Breeding. Jun-Nov, possibly much more extended, with birds seen at nest cavities in Feb and Apr. Nest in hole excavated by birds usually in arboreal termitarium or, sometimes, staghorn fern or moss clump. Eggs 2 (once), and 2 fledglings observed.

Movements. Observations on Halmahera suggest birds apparently travelling long distances in search of flowers.

Status and Conservation. Not globally threatened. CITES II. Generally common, and sometimes abundant e.g. in Bismarck Archipelago. Not a popular target of traders, mainly because most of the birds taken die before reaching the traders! Density of 30 birds/km² estimated in one area of SE New Guinea, and likewise on Halmahera.

Bibliography. Andrew (1992), Beehler (1978b), Beehler *et al.* (1986), Bell (1982), Bowler & Taylor (1989), Campbell (1981), Coates (1985), Coates & Bishop (1997), Cooke (1991a), Diamond (1972a), Finch & McKean (1987), Gilliard & LeCroy (1967a), Gregory (1995a, 1995b), Hadden (1981), Heron (1975), Hoogerwerf (1964a), Linsley (1995), Mack & Wright (1996), MacKinnon *et al.* (1995), Mayr & Rand (1937), Mees (1982a), Rand (1942b), Rand & Gilliard (1967), Ripley (1964), Schodde (1977), Smiet (1985), White & Bruce (1986).

45. New Caledonian Lorikeet

Charmosyna diadema

French: Lori à diadème

German: Diademlori

Spanish: Lori Diadema

Taxonomy. *Psitteuteles diadema* J. Verreaux and Des Murs, 1860, New Caledonia.

Monotypic.

Distribution. New Caledonia.

Descriptive notes. 19 cm. Only known from females, which are green with orange bill and legs, blue crown and yellow face; vague bluish tinge to lower thighs; red vent and base of lateral tail feathers, yellow underside of tail.

there is no explanation for the species's rarity.

Bibliography. Bregulla (1993), Collar & Andrew (1988), Collar *et al.* (1994), Dahl (1986), Greenway, J.C. (1967), Hannecart (1988), Hannecart & Létocart (1983), Low (1994b), Mayr (1945b), Sarasin (1913), Stokes (1980).

46. Red-throated Lorikeet

Charmosyna amabilis

French: Lori à gorge rouge

German: Rothörschen

Spanish: Lori Gorgirrojo

Taxonomy. *Trichoglossus (Glossopsitta) amabilis* E.P. Ramsay, 1877. Ovalau, Fiji Group, S. S. Islands.

Habitat. Forest, including by report the rain-forest—open *Melaleuca* woodland ecotone, also scrubland and perhaps cloud forest.

Food and Feeding. No information.

Breeding. No information.

Movements. No information.

Status and Conservation. ENDANGERED. CITES II. A BirdLife "restricted-range" species. The species is known from two specimens collected in 1859, reports published in 1913, and local albeit tenuous evidence in 1976. Cloud forest on Mt Panié, Mt Humboldt and the Massif de Kouakoué have been suggested as places worth searching for survivors, but

Formerly listed as *C. aureicincta*, a name described in the same year but now relegated to a synonym. Monotypic.

Distribution. Fiji, on Viti Levu, Vanua Levu, Ovalau and Taveuni.

Descriptive notes. 18 cm. Bright green, with orange bill and red area from lores to upper breast, latter thinly bordered yellow; thighs red, legs orange; tail tipped yellow, and yellowish below. Immature has only faint yellow on breast, and thighs greyish.

Habitat. In Habits upland rain forest at 120-1000 m, usually above 500 m, keeping to the canopy.

Food and Feeding. Known to take nectar, pollen and fruit.

Breeding. No information.

Movements. Presumably resident, but described as nomadic in search of flowering

trees.

Status and Conservation. VULNERABLE. CITES II. A BirdLife "restricted-range" species. Fairly common in at least one area of interior Viti Levu and widespread on Taveuni, 1973, though possibly extinct on Ovalau. Recently, however, it is reported as rare, and that the only confirmed records this century have been from Viti Levu, where recently only small flocks of up to six birds have been seen. The cause of the decline on or loss from other islands is not known but may be predation by black rats (*Rattus rattus*).

Bibliography. Clunie (1984), Collar *et al.* (1994), Dahl (1986), Fisher & Longmore (1995), Forshaw (1971a), Gorman (1975), Holyoak (1979), Low (1994b), Mayr (1945b), Pratt *et al.* (1987), Watling (1982a).

47. Duchess Lorikeet

Charmosyna margarethae

French: Lori de Margaret

German: Margarethenlori

Spanish: Lori de Margarita

Taxonomy. *Charmosyna margarethae* Tristram, 1879, Makira Harbour, San Cristobal, Solomon Islands. Monotypic.

Distribution. Solomon Is, including Bougainville.

Descriptive notes. 20 cm; 40-60 g. Mid- to hindcrown blackish, rest of head, throat and nape red; complete yellow ring, bordered on both sides by dull black, from breast onto sides of neck and upper back; vent green; tail red tipped yellow; upper back and wings green; lower back and rump olive green, red at sides; bill and legs orange. Female has yellow at sides of rump. Immature has less defined yellow ring, unbordered above, with dark scaling to body feathers.

Habitat. Forests, second growth and coconut plantations from sea-level into lower mountains up to 1350 m, apparently more numerous away

from lowlands though considered most frequent at 100-600 m. On Kolombangara and San Cristobal lower densities found in all lowland habitats including primary forest, highest numbers on San Cristobal being at 500-700 m.

Food and Feeding. Pollen, nectar and blossoms, and soft fruit, especially epiphytic *Schefflera*.

Breeding. Display by male to female observed, Jan; gonads of collected birds inactive in Jul, although locals report breeding at that time.

Movements. No information, but fluctuations in abundance would seem likely in response to phenology of flowering trees.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. Widespread and fairly common at least on Kolombangara, Guadalcanal and Bougainville; uncommon on Santa Isabel; common on San Cristobal, possibly owing to absence of *C. meeki*.

Bibliography. Buckingham *et al.* (1995), Cain & Galbraith (1956), Coates (1985), Collar *et al.* (1994), Dahl (1986), Diamond (1975a), Greensmith (1975), Hadden (1981), Mayr (1945b), Rothschild & Hartert (1901), Schodde (1977), Webb (1992, 1997).

48. Fairy Lorikeet

Charmosyna pulchella

French: Lori féérique

German: Goldstrichellori

Spanish: Lori Lindo

Other common names: Little Red Lorikeet

Taxonomy. *Charmosyna pulchella* G. R. Gray, 1859, Manokwari, New Guinea.

Populations of C and E formerly considered separate race, *bella*. Two subspecies recognized.

Subspecies and Distribution.

C. p. rothschildi (Hartert, 1930) - Cyclops Mts and adjacent ranges, N Irian Jaya.

C. p. pulchella G. R. Gray, 1859 - mountains of New Guinea from Vogelkop to Huon Peninsula and E Papua New Guinea.

Descriptive notes. 18-19 cm; 24-35 g. Red on head, nape and underparts except for purplish black patch on mid- to hindcrown, thin yellow streaks on breast, dusky thighs; wings green with red and green underwing-coverts and dark flight-feathers; rump patch dull blue, sometimes washed green; uppertail-coverts and proximal half of uppertail green, distal half red becoming yellow, underside yellow; bill and legs orange-red. Female has yellow patches on sides of rump. Immature has green in dark crown patch and thighs, and on breast, yellow band across underside of flight-feathers. Race *rothschildi* has crown patch joined to rear edge

of dark supercilium, large green breast patch, dull purplish belly, no blue rump; female more extensively green below.

Habitat. Forest, forest edge and secondary areas in lower hills and mid-montane areas, variably occurring at altitudes of 500-1800 m, sometimes in lowlands.

Food and Feeding. Feeds at canopy flowers presumably on pollen and nectar; large *Melicope* trees appear important, and inflorescences of *Elaeocarpus* and *Syzygium*.

Breeding. Dec-Jan, Apr. Nest a hole excavated in the base of an epiphyte. In captivity: 1-2 eggs; incubation apparently 25 days; nestling period 2 months.

Movements. Birds wander nomadically into lowlands at times, and presence in one area of uplands directly related to flowering of *Melicope*.

Status and Conservation. Not globally threatened. CITES II. Scarce in some areas, common in others, and locally abundant. Levels of trade, almost all out of Indonesia, generally low.

Bibliography. Andrew (1992), Beehler (1978b), Beehler *et al.* (1986), Brook (1914), Coates (1985), Diamond (1972a), Finch (1979b), Gilliard (1950a), Gilliard & LeCroy (1961), Greenway (1935), Gregory (1995a, 1995b), Harrison & Holyoak (1970), Inskipp *et al.* (1988), Mack & Wright (1996), Majnep & Bulmer (1977), Mayr & Rand (1937), Pratt (1982), Rand (1942b), Rand & Gilliard (1967), Ripley (1964).

49. Josephine's Lorikeet

Charmosyna josefinae

French: Lori de Joséphine

German: Josefinenlori

Spanish: Lori de Josefina

Other common names: Josephine's Lory

Taxonomy. *Trichoglossus josefinae* Finsch, 1873, Arfak Mountains.

Three subspecies recognized.

Subspecies and Distribution.

C. j. josefinae (Finsch, 1873) - W New Guinea from Vogelkop to Snow Mts.

C. j. cyclopum Hartert, 1930 - NC New Guinea in Cyclops Mts.

C. j. sepikiana Neumann, 1922 - C New Guinea from R Sepik and Western Highlands E to Mt Bosavi.

Descriptive notes. 23-25 cm. Plumage extensively red, with orange bill and legs, blue-streaked black patch from behind eye over rear crown and nape; black lower belly, flanks and thighs; olive green mantle and wings, but red underwing-coverts; small dull blue rump patch; outer tail feathers proximally green, distally yellow, tail tipped yellow and underside all yellow. Female has yellow patch on upper rump. Immature has green or blue tinge in black. Race *sepikiana* has grey instead of blue in crown, more black on belly; *cyclopum* largely lacks any blue crown streaking, and is only faintly dusky on belly.

Habitat. In habits forest, forest edge and partly cultivated land, generally at middle elevations, 760-1770 m.

Food and Feeding. Nectar, pollen and flower buds, taken in canopy trees and mid-storey epiphytes; a climbing vine with large white flowers noted to be important.

Breeding. Bird in breeding condition taken in Feb; no other information.

Movements. No information, but possibly nomadic.

Status and Conservation. Not globally threatened. CITES II. Considered to be generally sparse and local throughout most parts of range, although assessments may be biased by unobtrusive behaviour. Forest habitat not threatened at present, but likely to be affected in future; trade probably not a threat, although 697 were exported in 1986, mostly from Indonesia, and 459 in 1987, thereafter becoming much lower.

Bibliography. Andrew (1992), Anon. (1993, 1994a), Beehler *et al.* (1986), Campbell (1981), Clayton (1993), Coates (1985), Coates & Lindgren (1978), Gregory (1995a, 1995b), Low (1991g), Pagel & Greven (1990), Rand (1942b), Rand & Gilliard (1967), Ripley (1964), Rothschild (1931), de Ruiter (1993b).

50. Papuan Lorikeet

Charmosyna papou

French: Lori papou

German: Papualori

Spanish: Lori Rabilargo

Other common names: Fairy/Stella's Lorikeet, Papuan Lory

Taxonomy. *Psittacus Papou* Scopoli, 1786, Arfak.

Four subspecies recognized.

Subspecies and Distribution.

C. p. papou (Scopoli, 1786) - Vogelkop (W New Guinea).

C. p. goliathina Rothschild & Hartert, 1911 - Weyland Mts (Irian Jaya) E to Eastern Highlands of Papua New Guinea.

C. p. wahnesei Rothschild, 1906 - Huon Peninsula.

C. p. stellae A. B. Meyer, 1886 - Herzog Mts to Owen Stanley Range.

Descriptive notes. 36-42 cm; 74-113 g. Upper body and underparts red with blue band across mid-crown bordered black on hindcrown, black line on hindneck, broad black band on belly and thighs, yellow patch on side of breast and flank behind thigh; mantle, wings and tail dark green, with primary tips somewhat elongate and very long (20-25 cm) central tail streamers, tipped yellow; underwing-coverts red, underside of flight-feathers blackish; lower back and sides of rump red, central rump blue shading to green on uppertail-coverts; bill and legs orange. Female has yellow patch on lower back.

Immature duller, with less elongate wing and tail feathers. Race *goliathina* replaces yellow patch on breast with red, on flank with black, central tail feathers yellow for most of extended length; *stellae* similar but tail tips more orange; *wahnesei* has yellow breastband and green tinge to black on belly. All forms except nominate said to have a common (generally higher-altitude) melanistic morph, in which red is replaced by black and dark green; mixed red/black forms also occur.

Habitat. Montane forest at altitudes of 1500-3500 m, including disturbed *Nothofagus*-*Podocarpus* forest.

Food and Feeding. Recorded feeding on blossoms, flower buds, pollen, soft fruit of *Schefflera* and other trees, and also small seeds; has also been reported to consume insects (possibly ingested accidentally).

Breeding. Pair with enlarged gonads in Aug; young birds seen Oct-Nov. In captivity: 2 eggs; incubation lasting 3 weeks; nestling period around 7 weeks.

Movements. Numbers appear to build up and decline with local food supply, suggesting a degree of local nomadism.

Status and Conservation. Not globally threatened. CITES II. Reported to be fairly common throughout wide range; skins greatly prized as head decorations by highland people and are much traded.

Bibliography. Andrew (1992), Beehler (1978b), Beehler *et al.* (1986), Brook (1910), Coates (1985), Cooke (1995a), Diamond (1972a), Frith & Frith (1992), Gilliard & LeCroy (1961), Gregory (1995a, 1995b), Hadden (1975), Low (1973), Mayr & Gilliard (1954), Mayr & Rand (1937), Pratt (1982), Rand (1942b), Rand & Gilliard (1967), Ripley (1964), Rothschild (1931), Russell (1981a), Sims (1956).

Genus *OREOPSITTACUS* Salvadori, 1877

51. Plum-faced Lorikeet

Oreopsittacus arfaki

French: Lori bridé **German:** Arfaklori **Spanish:** Lori Bigotudo
Other common names: Whiskered Lorikeet

Taxonomy. *Trichoglossus (Charmosyna) Arfaki* A. B. Meyer, 1874, Arfak Mountains, 3500 feet (c. 1060 m), New Guinea.

Three subspecies recognized.

Subspecies and Distribution.

O. a. arfaki (A. B. Meyer, 1874) - Vogelkop (W Irian Jaya).

O. a. major Ogilvie-Grant, 1914 - Snow Mts (C Irian Jaya).

O. a. grandis Ogilvie-Grant, 1895 - C mountain ridge of Papua New Guinea.

Descriptive notes. 15-17 cm; 16-26 g. Bill black, entire crown above line through eye red; face below eye plum purple, with double string of white flecks from lores under eye to ear-coverts; postocular area adjoining sides of neck, nape, upperparts and tail dark green; primaries blue; underparts yellowish green, but sides of breast and underwing-coverts red, belly and lower flanks orange-red, yellow on sides of undertail-coverts; yellow band across undersides of secondaries; tail tipped reddish pink, underside all reddish. Female has no red on head. Immature similar, with black edges on upperparts, facial pattern less obvious. Race *major* larger,

with more extensive red tip to tail; *grandis* similar but lacks orange-red on belly and flanks.

Habitat. Montane mist forest at 2000-3750 m, including disturbed *Nothofagus-Podocarpus* forest. Occasionally found as low as 1000 m.

Food and Feeding. Nectar and perhaps pollen of *Dimorphanthera cf. cornuta*, flowers and fruits of *Schefflera*, berries; noted to feed not only in the crowns of trees but also on small fruits on lower growth inside forest; usually in pairs.

Breeding. Mating display observed in Jun, and breeding condition birds in Aug-Oct. No other information.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Fairly common but difficult to observe. Regular around Tari Gap, Papua New Guinea.

Bibliography. Andrew (1992), Anon. (1994a), Beehler (1978b), Beehler *et al.* (1986), Coates (1985), Diamond (1972a), Frith & Frith (1992), Gilliard & LeCroy (1961), Gregory (1995a, 1995b), Hopkins (1992), Low (1997c), Majnep & Bulmer (1977), Mayr & Rand (1937), Rand (1942b), Rand & Gilliard (1967), Ripley (1964).

Descriptive notes. 21-23 cm; 41-62 g. Bill yellow; head olive green, shading to russet on hindcrown, with light yellow streaks on crown and dense pale greenish streaks on face below eye; back and wings green, but wings mostly red below; throat and centre of both breast and belly red; sides of breast to lower belly and vent light green; tail green above with outer feathers basally red, yellow-orange below and at tips. Immature duller with less red on underparts. Race *major* larger and paler, facial streaks yellow.

Habitat. Mid-montane (e.g. *Nothofagus-Podocarpus*) forest, edge, secondary growth

and clearings, chiefly 1560-2660 m; seems to prefer disturbed areas and groves of casuarinas in garden areas.

Food and Feeding. *Schefflera* fruits recorded, also other fruits, berries, small hard seeds, caterpillars and lerps; also flowers of tall eucalypts and of weeds at ground level.

Breeding. Sept-Jan on circumstantial basis; however, evidence for around Jun, with juvenile and post-breeding male in late Aug. Nest reportedly in hole in tree, with 2 eggs (2 eggs in captivity).

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Common; one of few mid-montane birds to have profited from human clearance of forest, being numerous in cleared areas around villages.

Bibliography. Andrew (1992), Beehler (1978b), Beehler *et al.* (1986), Bell (1984b), Campbell (1979, 1981), Coates (1985), Diamond, J.M. (1972a, 1985), Gilliard & LeCroy (1961), Gregory (1995a, 1995b), Majnep & Bulmer (1977), Mayr & Gilliard (1954), Mayr & Rand (1937), Peckover & Filewood (1976), Rand & Gilliard (1967), Ripley (1964), Rothschild (1931), Sims (1956), Tavistock (1950), Thurlow (1989).

53. Orange-billed Lorikeet

Neopsittacus pullicauda

French: Lori émeraude **German:** Orangeschnabel-Berglori **Spanish:** Lori Montano Chico
Other common names: Emerald Lorikeet

Taxonomy. *Neopsittacus pullicauda* Hartert, 1896, Victoria District, Owen Stanley Range, New Guinea.

Three subspecies recognized.

Subspecies and Distribution.

N. p. alpinus Ogilvie-Grant, 1914 - WC New Guinea from Snow Mts to area around Mt Capella.

N. p. socialis Mayr, 1931 - Huon Peninsula and Herzog Mts, EC Papua New Guinea.

N. p. pullicauda Hartert, 1896 - E New Guinea from area around Mt Capella to Owen Stanley Range.

Descriptive notes. 18 cm; 25-40 g. Very similar to *N. musschenbroekii* but smaller, bill orange, no olive tinge and narrower yellow streaking on crown; red more continuous on underparts. Immature duller, with reduced red, brownish bill. Race *socialis* like nominate but darker; *alpinus* has orange breast.

Habitat. Canopy of mossy cloud forest and adjacent cleared areas on high mountains up to 3800 m, descending, albeit rarely, as low as 1600 m.

Food and Feeding. Somewhat more nectarivorous than congener (although both may consume flowers more than sympatric *Oreo-*

psittacus arfaki and *Charmosyna papou*), but also takes seed cones of gymnosperm *Papuacedrus papuanus*, and fleshy berries of *Sericolea pullei*.

Breeding. Oct. Nest reportedly in hole in tall tree, with 2 eggs.

Movements. No information, but record from as low as 800 m indicates occasional vagrancy from high elevations, and regular or irregular vertical movements may be usual.

Status and Conservation. Not globally threatened. CITES II. Generally common and little affected by habitat loss or trade.

Bibliography. Andrew (1992), Beehler (1978b), Beehler *et al.* (1986), Bell (1984b), Clear (1993), Coates (1985), Diamond (1972a), Gilliard & LeCroy (1961), Gregory (1995a, 1995b), Hopkins (1992), Junge (1953), Majnep & Bulmer (1977), Mayr & Gilliard (1954), Mayr & Rand (1937), Peckover & Filewood (1976), Rand (1942b), Rand & Gilliard (1967), Ripley (1964).

Genus *NEOPSITTACUS* Salvadori, 1875

52. Yellow-billed Lorikeet

Neopsittacus musschenbroekii

French: Lori de Musschenbroek **German:** Gelbschnabel-Berglori **Spanish:** Lori Montano Grande
Other common names: Musschenbroek's Lorikeet

Taxonomy. *Nanodes Musschenbroekii* Schlegel, 1873, Hatam, Arfak, New Guinea.

Two subspecies recognized.

Subspecies and Distribution.

N. m. musschenbroekii (Schlegel, 1873) - Vogelkop (Irian Jaya).

N. m. major Neumann, 1924 - C New Guinea from Snow Mts E to Huon Peninsula and Owen Stanley Range.

Subfamily PSITTACINAE

Tribe PSITTRICHADINI

Genus *PSITTRICHAS* Lesson, 1831

54. Pesquet's Parrot

Psittrichas fulgidus

French: Psittrichas de Pesquet **German:** Borstenkopf **Spanish:** Loro Aguileño
Other common names: Vulturine/Bare-headed Parrot

Taxonomy. *Banksianus fulgidus* Lesson, 1830, New Guinea. Relationships uncertain and taxonomic position remains somewhat controversial; has been associated with Loriinae, but also shows affinities with Nestorini (see page 282). Monotypic.

Distribution. Mountains of New Guinea.

Descriptive notes. 46 cm; 690-800 g. Bill, bare face to behind eye and head and upperparts black, with vague red patch behind eye, dull red uppertail-coverts, and red median and greater wing-coverts and outer secondaries; throat to upper belly black with greyish edging, making scaled effect; belly to undertail-coverts red; tail black. Female lacks red patch behind eye. Immature is duller red.

Habitat. Primary and tall secondary forest in foothills and lower mountains from 600 to 1200 m, occasionally ranging into lowlands and almost to 2000 m.

Food and Feeding. Appears to be a specialist on fruits of certain figs (*Ficus*), in particular an unidentified species with a hard pericarp, but other soft fruit also taken, including mangoes and climbing pandans. Blossoms and nectar, and flowers of *Freyinetia*, also reported.

Breeding. Breeding condition birds in Feb. Apr, May; fledged juveniles in Dec. Nest apparently unreported. Usual brood size appears

to be 2. In captivity: 2 eggs; incubation lasting 27 or 31 days.

Movements. No information.

Status and Conservation. **VULNERABLE.** CITES II. Marked variations in local abundance, with flocks of up to 20 recorded. Although still not uncommon in remote areas, numbers have declined drastically on account of hunting pressure, and the species has disappeared from forest near human habitation. Skins are used as "bride" price in the highlands, costing around K20 in markets, and are even more valuable than bird-of-paradise plumes; however, birds are also used for food. Deforestation is also afflicting the species and to some extent trapping for the bird trade.

Bibliography. Andrew (1992), Beehler (1978b), Beehler *et al.* (1986), Bell (1969a), Bishop (1987), Cher (1994), Coates (1985), Collar *et al.* (1994), Courtney (1997a), Cunningham (1990), Diamond (1972a), Dyck (1977), Gregory (1995a, 1995b), Homberger (1981), de Jager (1976a, 1976b), Low (1990b, 1991i, 1992e, 1994b), Mack & Wright (1996), Mayr (1937), Ogilvie-Grant (1915), Rand (1942a, 1942b), Rand & Gilliard (1967), Schmid (1993), Schodde & Hitchcock (1968), Thurslund & Paul (1987).

Tribe NESTORINI

Genus *NESTOR* Lesson, 1830

55. Kea

Nestor notabilis

French: Nestor kéa

German: Kea

Spanish: Kea

Taxonomy. *Nestor notabilis* Gould, 1856, Murihiku District, South Island, New Zealand. Monotypic.
Distribution. Mountains of South I, New Zealand.

Descriptive notes. 48 cm; adult mean 922 g. Brown head and underparts with indistinct blackish edges to feathers, shading to dull bronze green on back and wings with stronger black scaling; outer webs of primaries dull blue; underwing-coverts reddish orange with yellow barring and notching to bases of undersides of flight-feathers; lower back to uppertail-coverts dull reddish, scaled black; tail above bronze green with dark subterminal bar, below dull yellow with dark subterminal bar and buffy tips. Female slightly smaller, with shorter, less curved bill. Immature has yellowish crown, yellow cere.

Habitat. Wooded valleys and *Nothofagus* forests bordering subalpine scrublands at 600-2000 m, occupying the upper scrub and grassland zones in summer, moving higher for berries in autumn before descending below the timberline in winter.

Food and Feeding. Changes through year. In Jan birds feed on flowering mountain flax (*Phormium colensoi*), rata (*Metrosideros*) and other trees and shrubs, then berries of snow totara (*Podocarpus nivalis*) from late Jan to coming of snow. Other non-seasonally grouped foods include fruits of *Coprosma ciliata*, *Cyathodes fraseri*, *Muehlenbeckia axillaris*, *Pentachondra pumila* and *Astelia nervosa*, and leaves of *Senecio scorzonoides*. Birds also take flesh and bone-marrow from carcasses and scavenge on rubbish dumps.

Breeding. Chiefly Jul-Jan, although recorded at all times of year except late autumn. Nest in crevice under rocks or in tree roots, or in hollow log. Eggs 2-4; incubation lasts 3-4 weeks; nestling period 13 weeks. Young males appear to disperse from natal area, while young females remain; however, mortality in male birds appears to be very much higher, since despite polygynous mating system there generally appears to be a surplus of females, not males. As few as 10% of adult males may breed in any given year, this in part due to polygyny by dominant male birds.

Movements. Juveniles form wandering flocks in autumn.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. Total population estimated very crudely at 1000-5000 birds around 1985, based on an assumed and unsupported density of 2-10 birds/84 km², but other evidence suggesting 30-5 birds/84 km² indicates possibly 15,000 birds, 1992; however, if Keas show higher densities around car-parks, refuse dumps and ski resorts then this figure may be far too high. Once seriously persecuted in the belief that birds kill sheep, with 6819 killed in the years 1943-1946; now established that attacks on living sheep are extremely rare and only involve already injured or diseased animals.

Bibliography. Anderson (1986), Bolton (1997), Bond & Diamond (1992), Bond *et al.* (1991), Chambers (1989), Clarke (1970), Cunningham, A. (1974), Cunningham, J.M. (1948), Dawson (1959), Diamond & Bond (1991), Falla *et al.* (1981), Fingland (1994), Jackson (1960, 1962a, 1962b, 1963b, 1969), Keller (1975), Kinsky (1970), Kirk *et al.* (1993), Liedek (1995), McCaskill (1954), Peat (1994), Potts (1976, 1977), Riney *et al.* (1959), Robertson (1985), Schmidt (1971), Smith, G.A. (1996), Soper (1976), Tebbich *et al.* (1996), Williams (1975), Zeigler (1975).

56. Kaka

Nestor meridionalis

French: Nestor superbe

German: Kaka

Spanish: Kaka

Taxonomy. *Psittacus meridionalis* J. F. Gmelin, 1788, Dusky Sound, South Island, New Zealand. Probably formed superspecies with *N. productus*, formerly of Norfolk I and nearby Philip I, a species which became extinct in mid-19th century. Two subspecies recognized.

Subspecies and Distribution.

N. m. septentrionalis Lorenz, 1896 - North I and some offshore islands.

N. m. meridionalis (J. F. Gmelin, 1788) - South I, Stewart I and larger offshore islands.

Descriptive notes. 45 cm; average 550 g. Forehead to nape whitish, lightly edged buff; face brown with broad pinkish flecks that become yellow on ear-coverts; colours of head shade to olive-grey on nape and dull rust-red, lightly scaled black, on upper mantle, latter colour extending onto lower neck, flanks, belly, undertail-coverts, rump and uppertail-coverts; throat and breast, lower mantle, upper back and wings scaled brownish grey. Female has shorter and less curved bill. Immature similar to adult with pale eye-ring. Race *septentrionalis* duller, darker and smaller.

Habitat. Remaining areas of lowland and mid-altitude native forest.

Food and Feeding. Fruits, including *Podocarpus ferrugineus*, *Beilschmiedia tarairi*, berries, seeds (notably of *Agathis australis*), flowers, buds, nectar and invertebrates. Sap of *Pseudopanax colensoi*, *Griselinia littoralis*, *Nothofagus solandri*, *Metrosideros umbellata* and, on Stewart I, *Dacrydium cupressinum* important in winter, along with winter-flowering puriri (*Vitex lucens*) and kohekohe (*Dysoxylum spectabile*). Honeydew from the scale insect *Ultracoelostoma assimile* is critically important in *Nothofagus* forest in summer and autumn, while larvae of the longhorn beetle *Ochrocydus huttoni* are protein-rich but expensive in energy to obtain. Recorded feeding in kiwifruit orchard, Sept, and on flax flowers, Jan.

Breeding. Sept-Mar. Nest in large hollow in limb or trunk, also in hollow base of cabbage tree; on Kapiti commonly below 3 m, and the preferred trees being *Melictytus ramiflorus* and *Dysoxylum spectabile*. Eggs 2-5; incubation c. 3 weeks; nestling period 9-10 weeks; young dependent on food provision by parents for 4-5 months. Hatching success fairly low (56% on Kapiti in successive seasons 1988-1989); reproductive rate apparently very low, with low numbers of breeding attempts per year.

Movements. Birds are partly nomadic, sometimes appearing in areas from which they have been absent for some time. In winter birds appear to wander into more open country.

Status and Conservation. VULNERABLE. CITES II. The species has suffered chronic decline owing to habitat clearance, and mainland populations face further declines owing to predation by introduced stoats and rats, competition for honeydew from introduced wasps and possums (which appears to have a disastrous impact on breeding performance), and continuing habitat clearance. Its numbers remain high only on offshore islands such as Little Barrier, Codfish and Kapiti.

Bibliography. Beggs & Wilson (1987, 1988, 1991), Chambers (1989), Collar *et al.* (1994), Dawson (1959), Falla *et al.* (1981), Fingland (1994), Imber (1967), Jackson (1963a, 1971), Kinsky (1970), Kirk *et al.* (1993), Liedek (1997), Matthews (1980), Moorhouse (1991), Moorhouse & Greene (1995), O'Donnell (1993), O'Donnell & Dilks (1989, 1993), O'Donnell & Rasch (1991), Roberts (1953), Robertson (1985), Sibson (1947), Skipworth (1965), St. Paul (1977), Turbott (1952, 1990), Williams (1975).

Tribe STRIGOPINI

Genus *STRIGOPS* G. R. Gray, 1845

57. Kakapo

Strigops habroptilus

French: Strigops kakapo

German: Kakapo

Spanish: Kakapo

Taxonomy. *Strigops habroptilus* G. R. Gray, 1845, Dusky Sound, South Island. Monotypic.

Distribution. New Zealand, formerly on North I, South I and Stewart I, with subfossil remains from Chatham Is; persisted until 1989 in Milford District of Fiordland in South I, and until 1992 on SE Stewart I. Now survives as introduced populations on Codfish I, Maud I and Little Barrier I.

Descriptive notes. 64 cm; 950-3000 g. Green above, mottled with blackish chevrons and brownish blotches, tail patterned greenish yellow, brown and black; yellowish below, with notches and bars of buff and green; superciliary stripe lemon yellow; forehead, face and ear-coverts yellowish brown with elongate rictal bristles. Female no different in size but less heavy. Immature duller, face browner.

Habitat. Primarily mossy *Nothofagus* forests, particularly where adjacent to open ground along river flats or the subalpine scrub belt bordering snow tussock *Danthonia* meadows. Birds shelter by day in low trees, rock crevices, burrows amidst roots or under shrubs, becoming active at night.

Food and Feeding. Versatile and opportunistic vegetarians with different seasonal diets: fruits, berries, nuts, seeds, green shoots, leaf buds, roots, rhizomes, tubers, bark, stems, moss, fungi. On Stewart I main food plants are *Blechnum* fern fronds, followed by *Dracophyllum*, *Gahnia* and *Astelia*, plus *Lycopodium*, *Schizaea*, *Cyathodes*, *Olearia*, *Thelymitra*, *Oreobolus* and *Carex*, with new growth and developing foliage targeted in spring and summer, and subterranean parts of plants from autumn through to early spring; fruit of *Fuchsia* reportedly important, and crops of some birds were filled with moss. Absence of reproductive behaviour in certain years is linked to erratic availability of certain food, once thought to be tussock and grass seed, but apparently (on Stewart I and Codfish I) autumn mast production of podocarps. Even chicks in first weeks of life are not fed animal food, but *Agathis australis* leaves apparently important and fruits and leaves of rimu (*Dacrydium cupressinum*).

Breeding. Dec-Feb, once as late as May. Birds form no pair-bond and males lek vocally to attract females at night, but in some years all activity is suspended. Nest is a burrow in large crevice between rocks or tree roots. Eggs 1-2, rarely 3, evidently with long intervals between laying of first and second eggs; incubation c. 30 days; nestling period c. 3½ months. Females have been known to breed at 9 and 11 years old, but may be able to do so earlier.

Movements. Sedentary (flightless).

Status and Conservation. CRITICALLY ENDANGERED. CITES I. In steady retreat since human occupation of New Zealand, present species appears to have begun its catastrophic decline when European settlement resulted in the establishment of alien predators, notably the stoat (*Mustela erminea*) and black rat (*Rattus rattus*), although on Stewart I the principal cause of decline was feral cats, and it is now judged that even Polynesian rats (*R. exulans*) are serious threats to nesting birds. From 1987 to 1992 all 37 remaining birds on Stewart I were translocated to the predator-free islands of Codfish, Maud and Mana (failing to establish on Mana), so that with a population already transferred to Little Barrier I the species is now extinct throughout its natural range. Supplementary feeding induced breeding in four out of five years on Little Barrier, and by Mar 1994 the total population was a minimum 47 birds, 30 males and 17 females; however, only eight of latter were proven breeders, some 87% of remaining birds were then over 14 years old, and there was continuing high chick mortality due to starvation and predation. By Jan 1997 total population was up to 50 birds, including 19 females. First breeding on Codfish I in 1992, but of six chicks hatched only one survived, largely due to failure of rimu crop; surviving chick was hand-reared, and might shortly be old enough to breed. Total of four chicks hatched on Codfish I in early 1997, the first breeding anywhere since 1993.

Bibliography. Tribe MICROPSITTINI

Genus *MICROPSITTA* Lesson, 1831

58. Yellow-capped Pygmy-parrot

Micropsitta keiensis

French: Micropsitte pygmée

Spanish: Microloro de las Kai

German: Gelbkappen-Spechtpapagei

Taxonomy. *Nasiterna keiensis* Salvadori, 1875. Kai Islands.

Forms a superspecies with *M. geelvinkiana* and *M. pusio*. Three subspecies recognized.

Subspecies and Distribution.

M. k. keiensis (Salvadori, 1875) - Kai Is and Aru Is.

M. k. chloroxantha Oberholser, 1917 - W Papuan Is, Vogelkop and Onin Peninsula, W Irian Jaya.

M. k. viridipectus (Rothschild, 1911) - S New Guinea.

Descriptive notes. 9 cm; 11-14 g. Most of plumage green, but crown dusky yellow, shading to green at rear, and upper face ochre, shading to green below. No apparent sex or age differences. Race *viridipectus* supposedly darker than nominate; *chloroxantha* has variable orange-red midline down lower breast and belly.

Habitat. Lowland and hill forest, coconut plantations, mangroves, nypa forest, even visiting trees in villages; usually in understorey. On Kai Is ranges to 250 m.

Food and Feeding. Presumably fungus and lichen taken by bark-gleaning on trunks of flowering trees, particularly figs; most stomach contents are an indeterminate paste, but small seeds found.

Breeding. Sept-Mar on basis of nestling in Oct, breeding condition male in Nov, nest with young in Mar. Nest in hollow excavated in arboreal termitarium 3-4 m from ground. In one nest there were 6 adults as well as 2 nestlings, since the nest was also used for roosting by young from previous broods.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Very common on Kai Is, scarce on Aru Is (apparently naturally), moderately common throughout W Papuan Is.

Bibliography. Andrew (1992), Beehler *et al.* (1986), Bergman (1960), Coates (1985), Coates & Bishop (1997), Erftemeijer *et al.* (1991), Hartert (1901), Hoogerwerf (1971), Mayr & Rand (1937), Rand & Gilliard (1967), Ripley (1964), White & Bruce (1986).

59. Geelvink Pygmy-parrot

Micropsitta geelvinkiana

French: Micropsitte de Geelvink

Spanish: Microloro de Geelvink

German: Geelvinkspechtpapagei

Taxonomy. *Nasiterna pygmaea geelvinkiana* Schlegel, 1873. Mafor.

Forms a superspecies with *M. keiensis* and *M. pusio*. Two subspecies recognized.

Subspecies and Distribution.

M. g. geelvinkiana (Schlegel, 1873) - Numfor I, Geelvink Bay.

M. g. misoriensis (Salvadori, 1875) - Biak I, Geelvink Bay.

Descriptive notes. 9 cm; 13-17 g. Most of plumage green, but crown and face dark brownish blue, bluer on throat, with yellow arc on hindcrown, broad orange yellow centre to underparts from breast to undertail-coverts. Female has green underparts and duller face; lacks yellow on crown. Immature undescribed. Race *misoriensis* has head brown.

Habitat. Primary and secondary forest, including regrowth as low as 4 m high, woodland edge adjacent native gardens. Recorded only up to 150 m.

Food and Feeding. Probably lichen and fungus off bark, as in other *Micropsitta*; crushed

seeds were in the stomach of a collected bird.

Breeding. Bird with slightly developed gonads in Dec; nest construction in Jun, and 2 nestlings also in Jun. Nest in arboreal termitarium.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. Well distributed in good numbers in lowland secondary and remnant primary forest patches on Biak, and throughout adjacent Supiori (off NW Biak).

Bibliography. Andrew (1992), Beehler *et al.* (1986), Collar *et al.* (1994), Mayr & Meyer de Schauensee (1939a), Rand & Gilliard (1967), Rothschild *et al.* (1932), Sujatnika *et al.* (1995).

60. Buff-faced Pygmy-parrot

Micropsitta pusio

French: Micropsitte à tête fauve

German: Braunstirn-Spechtpapagei

Spanish: Microloro Pusio

Taxonomy. *Nasiterna pusio* P. L. Slater, 1866, Solomon Islands; error = Duke of York Island.

Forms a superspecies with *M. keiensis* and *M. geelvinkiana*. All races very similar and validity has been questioned, as characters are not obvious and provenance of some material currently in doubt; species may be better considered monotypic. Four subspecies tentatively recognized.

Subspecies and Distribution.

M. p. beccarii (Salvadori, 1876) - N New Guinea from W Geelvink Bay to Kumusi R, and islands of Manam, Karkar, Bagabag and Rook.

M. p. pusio (P. L. Slater, 1866) - SE New Guinea and Bismarck Archipelago.

M. p. harterti Mayr, 1940 - Fergusson I (D'Entrecasteaux Is).

M. p. stresemanni Hartert, 1926 - Misima I and Tagula I (Louisiade Archipelago).

Descriptive notes. 8 cm; 10-15 g. Generally green, more yellowish on underparts; forehead and face buff-ochre, sometimes with yellowish superciliary stripe; central crown to nape deep blue; back and wings green, with black spotting on median wing-coverts; undertail-coverts yellow; tail blue centrally, black laterally with small yellow spots at tips. Female has paler face and crown. Immature has green crown. Race *harterti* greener below, throat washed blue; *stresemanni* like *harterti* but yellower below; *beccarii* darker, with duller brown face.

Habitat. Lowland and floodplain gallery forest, tall secondary growth and trees in clearings, sometimes dense savanna and coconut stands, up to 800 m, although only common up to 400 m.

Food and Feeding. Lichen, bark fungus, and probably termites; insect remains, tiny black seeds, yellow fruit flesh and flowers in stomachs.

Breeding. Dec-May. Nest in hole excavated in arboreal termitarium, in one case that of *Microcerotermes biro* about 2 m above ground on the trunk of a small tree in secondary forest. Eggs 2-3.

Movements. Wandering groups noted in extreme E of range, but whether there is true nomadism or birds simply range over large home ranges over several weeks is not known.

Status and Conservation. Not globally threatened. CITES II. Very uncommon or local on Sepik R, but common in Owen Stanley Range foothills, SE Papua New Guinea, where density estimated at 20 birds/km². Common, Bismarcks and Bagabag. Abundance may be underestimated owing to unobtrusive habits, e.g. infrequently seen near Port Moresby yet calls suggest it to be most abundant parrot in area.

Bibliography. Andrew (1992), Bailey (1992a), Baptista (1990), Beehler (1978b), Beehler *et al.* (1986), Bell (1982, 1984b), Coates (1985), Diamond & LeCroy (1979), Finch & McKean (1987), Gilliard & LeCroy (1966, 1967a), Mack & Wright (1996), Mayr & Rand (1937), Pearson (1975b), Rand & Gilliard (1967), Ripley (1964), Shanahan (1969).

61. Yellow-breasted Pygmy-parrot

Micropsitta meeki

French: Micropsitte de Meek

German: Meekspechtpapagei

Spanish: Microloro de Meek

Other common names: Meek's Pygmy-parrot

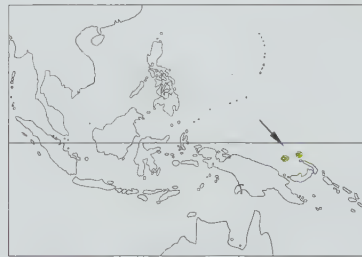

Taxonomy. *Micropsitta meeki* Rothschild and Hartert, 1914, Manus, Admiralty Islands.

Two subspecies recognized.

Subspecies and Distribution.

M. m. meeki Rothschild & Hartert, 1914 - Admiralty Is.

M. m. proxima Rothschild & Hartert, 1924 - St Matthias and Squally Is.

Descriptive notes. 10 cm. Head dusky grey-brown with light barring, usually with indistinct yellow superciliary; nape and underparts yellow with weak brown edging, giving vague scaled effect; back and wings green, with black spotting on median wing-coverts; tail green above, grey and yellow below. Immature undescribed. Race *proxima* has paler head with distinct yellow superciliary.

Habitat. Primary and degraded forest, apparently commoner in latter.

Food and Feeding. Seen pecking at small warty protuberances, apparently fungi, on smooth-barked tree; also seen nibbling lichen

off tree-trunk.

Breeding. One nest reported to have been found in arboreal termitarium, only 25 cm above ground; however, the source of this record is unclear. No further information available.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Common on Manus and Lou.

Bibliography. Coates (1985), Dutton & Newman (1991), Eastwood (1995a), Greensmith (1975), Gregory (1995c), Hartert (1926b), Sibley (1951).

62. Green Pygmy-parrot

Micropsitta finschii

French: Micropsitte de Finsch

German: Salomonenspechtpapagei

Spanish: Microloro de Finsch

Other common names: Finsch's Pygmy-parrot

Taxonomy. *Nasiterna finschii* E. P. Ramsay, 1881, San Cristobal, Solomon Islands.

Five subspecies recognized.

Subspecies and Distribution.

M. f. viridifrons (Rothschild & Hartert, 1899) - New Hanover, New Ireland and Lihir Is.

M. f. nanina (Tristram, 1891) - N Solomon Is of Bougainville, Choiseul and Santa Isabel.
M. f. tristrami (Rothschild & Hartert, 1902) - W Solomon Is of Vella Lavella, Gizo, Kolombangara, New Georgia, Rubiana and Rendova.
M. f. aolae (Ogilvie-Grant, 1888) - EC Solomon Is in Russell Is, Guadalcanal and Malaita.
M. f. finschii (E. P. Ramsay, 1881) - SE Solomon Is of Uki, San Cristóbal and Rennell.

Descriptive notes. 8-9 cm; 12-18 g. Green throughout, paler on underparts; vague blue around base of lower mandible; black spotting on median wing-coverts; belly spot orange-red; undertail-coverts yellow; tail greenish blue centrally, black laterally. Female has pink around base of lower mandible, no belly spot. Immature similar. Race *aolae* darker above, with blue patch on crown and no belly spot; *tristrami* like nominate without belly spot; *nanina* like *aolae* but with less blue on crown; *viridifrons* like *aolae* with more blue on crown extending onto sides of head, sometimes also with red belly spot.

Habitat. Chiefly primary forest but also second growth, shade trees and trees in clearings between 500-1000 m, possibly lower, but in S Bougainville largely confined to subcanopy and substage of unmosed primary forest with an open understorey at 600-750 m; in E Solomons generally occurs up to cloud forest where replaced by *M. bruijnii*, but different altitude limits at which birds become rare noted for Kolombangara (490 m) and San Cristóbal (900 m). Occasionally frequents coconut groves and casuarinas.

Food and Feeding. Birds feed on relatively clear trunks and limbs of trees, pecking off bark and pieces of fungus and lichen; remains of small scaled insects found alongside indeterminate vegetable matter in stomachs. Some birds noted apparently following slow-moving mixed bird flocks.

Breeding. Mar-Apr. Guadalcanal. Reported to nest in low arboreal or terrestrial termite mound.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Fairly common. Bismarcks, and throughout most of Solomons although affected by forest loss on Guadalcanal. Abundant within narrow elevation range, S Bougainville. On Kolombangara densities much higher in lowland primary forest than secondary growth.

Bibliography. Bradley & Wolff (1956), Bregulla (1976), Buckingham *et al.* (1995), Cain & Galbraith (1956), Coates (1985), Finch & McKean (1987), Greensmith (1975), Hadden (1981), Hindwood (1959), Mayr (1945b), Nicholson (1974), Schodde (1977), Sibley (1951), Webb (1992, 1997).

63. Red-breasted Pygmy-parrot

Micropsitta bruijnii

French: Micropsitte de Bruijn **German:** Rotbrust-Spechtpapagei **Spanish:** Microloro Pechirrojo
Other common names: Rose-breasted/Mountain Pygmy-parrot

Taxonomy. *Nasiterna bruijnii* Salvadori, 1875. Mount Arfak.

A distinct yellow-crowned form has been noted in Ok Tedi region of Papua New Guinea. Race *pileata* known in museums from only three male skins, none of which shows great differences from the variation present in nominate race. Four subspecies currently recognized.

Subspecies and Distribution.

M. b. pileata Mayr, 1940 - Buru and Seram, in S Moluccas.

M. b. bruijnii (Salvadori, 1875) - mountains of New Guinea from Vogelkop in W to Owen Stanley Range in E.

M. b. necopinata Hartert, 1925 - New Britain and New Ireland.

M. b. rosea Mayr, 1940 - Bougainville, Guadalcanal and Kolombangara, in Solomon Is.

Descriptive notes. 8-9 cm; 12-16 g. Forehead rusty shading to dull blue on hind-crown, nape, sides of neck and frontal half-collar; face yellow shading redder on ear-coverts; breast to undertail-coverts orange-red; back and flanks green; wings green with black spotting on median wing-coverts; tail blue centrally, black laterally. Female has whitish buff forehead and face, blue crown, rest green with yellow underparts. Immature like female with whitish forehead and face. Race *pileata* claimed to have deeper and more extended rust-red on crown, although this is not readily apparent on the only skins; *necopinata* has deep brown

crown, yellowish in centre, with red-orange face and yellow undertail-coverts; *rosea* has crown reddish pink, face pinker than nominate.

Habitat. Canopy of dense hill forest at 700 m, cloud forest at 1300 m, moss forest at 2000 m; range generally 500-2300 m although seen in lowlands on Buru; also forest edge and *Albizia* shade trees in coffee plantations, occasionally in coffee plantations and riparian growth. Not found in moss forest. Kolombangara, although common in tall montane forest up to 1300 m.

Food and Feeding. Food gleaned methodically from on or under bark in upper branches of trees, sometimes with regular mechanical pecking action, but stomach contents usually indeterminate; fungus, lichen and moss have been observed being taken; white paste found in stomachs may be corollas of white-flowered *Schefflera*, which contain a great deal of nectar. Has been seen feeding on fruit and possibly also flowers and lichen in canopy of *Syzygium* tree.

Breeding. Dec-Apr. Nest is hole in dead stump or tree, 3-4 m from ground; one was apparently attended by a male and two females.

Movements. Probably nomadic, although in places possibly a regular migrant, e.g. reportedly an annual visitor to lowlands of Buru at the start of the dry season in Oct/Nov; thought nomadic on New Britain.

Status and Conservation. Not globally threatened. CITES II. Usually considered uncommon to rare on Seram and Buru, but easily overlooked. Widespread but local in New Guinea; undescribed form at Ok Tedi common, with 650 counted flying NE in Nov 1992. Common locally in Bismarck Archipelago; common on Kolombangara.

Bibliography. Andrew (1992), Beehler (1978a, 1978b), Beehler *et al.* (1986), Bishop (1987), Buckingham *et al.* (1995), Coates (1985), Coates & Bishop (1997), Diamond (1972a), Finch & McKean (1987), Gilliard & LeCroy (1961, 1967a), Gregory (1994, 1995a, 1995b), Hadden (1981), Hyndman & Frodin (1980), Jepsen (1993), Mayr (1945b), Mayr & Rand (1937), Pratt (1982), Rand (1942b), Rand & Gilliard (1967), Schodde (1977), Siebers (1930), White & Bruce (1986).

Tribe CYCLOPSITTACINI

Genus *CYCLOPSITTA* Reichenbach, 1850

64. Orange-breasted Fig-parrot

Cyclopsitta gulelmitertii

French: Psittacule à poitrine orange

German: Orangebrust-Zwergpapagei

Spanish: Lorito Pechinaranja

Other common names: William's Fig-parrot

Taxonomy. *Psittacula gulelmi* III Schlegel, 1866. Salawati and New Guinea. Controversy concerning application of correct genus name; junior synonym *Opopsitta* sometimes erroneously used. Seven subspecies recognized.

Subspecies and Distribution.

C. g. melanogenia (Schlegel, 1866) - Aru Is.

C. g. gulelmitertii (Schlegel, 1866) - Salawati and W Vogelkop, New Guinea.

C. g. nigrifrons (Reichenow, 1891) - N New Guinea.

C. g. ramuensis (Neumann, 1915) - NE New Guinea around R Ramu.

C. g. fuscifrons (Salvadori, 1876) - S New Guinea.

C. g. amabilis (Reichenow, 1891) - Huon Peninsula eastwards, Papua New Guinea.

C. g. suavisissima P. L. Sclater, 1876 - SE Papua New Guinea.

Descriptive notes. 13 cm; 27-34 g. Dark green above; forehead to below and behind eye dark blackish blue; lores, throat and sides of head pale yellow; breast and upper belly orange; lower belly to vent yellowish green; flight-feathers dark blue. Female has orange ear-coverts, dark border to yellow cheeks, and greenish breast. Immature not clearly described. Race *nigrifrons* replaces blue with black; *ramuensis* has variable mixture of blue and black in crown; *amabilis* has blue suffusion in black crown, male having orange breast and upper belly, female with face to upper belly pale cream; *suavisissima* like nominate but forehead darker, yellow area whitish with large black patch from chin to ear-coverts; *fuscifrons* like *suavisissima* but forehead brown; *melanogenia* female has more greenish breast.

Habitat. Rain- and monsoon forest, gallery and savanna woodland, *Melaleuca* swamp forest, partly cleared areas, in lowlands and hills up to 1100 m.

Food and Feeding. Seeds of figs (*Ficus*) probably main staple, but also seeds of *Glochidion*, whose fruits are broken apart, and *Acacia auriculaeformis*; also apparently the inflorescences of *Poikilospermum*.

Breeding. Dec-Jun, but nest cavity visits and advertisement in Sept-Oct, when begging juveniles also noted. Nest in hole excavated in arboreal termitarium, with two or more active nests found in the same mound.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Common at Crater Mountain and other parts of S of range, where at one site density estimated at 30 birds/km², and at Ok Tedi in WC Papua New Guinea (subspecies unknown), but local in N of range, and some subspecies appear to be very rare.

Bibliography. Andrew (1992), Beehler *et al.* (1986), Bell (1982, 1984b), Bell & Coates (1979), Bellchambers *et al.* (1994), Coates (1985), Diamond (1972a), Gregory (1995a, 1995b), Mack & Wright (1996), Mayr & Rand (1937), Rand (1938), Rand & Gilliard (1967), Sweeney (1994e).

65. Double-eyed Fig-parrot

Cyclopsitta diophthalma

French: Psittacule double-œil

German: Rotwangen-Zwergpapagei

Spanish: Lorito Doblejojo

Other common names: Dwarf/Blue-faced/Red-faced/Two-eyed Fig-parrot

Taxonomy. *Psittacula diophthalma* Hombron and Jacquinot, 1841, southern coast of New Guinea = Triton Bay.

Controversy concerning application of correct genus name; junior synonym *Opopsitta* sometimes erroneously used. Race *coxeni* may be an incipient species. Eight subspecies recognized.

Subspecies and Distribution.

C. d. diophthalma (Hombron & Jacquinot, 1841) - W Papuan Is and W New Guinea.

C. d. aruensis (Schlegel, 1874) - Aru Is and extreme S New Guinea.

C. d. coccineifrons (Sharpe, 1882) - E New Guinea.

C. d. virago (Hartert, 1895) - Goodenough I and Fergusson I (D'Entrecasteaux Is).

C. d. inseparabilis (Hartert, 1898) - Tagula I (Louisiade Archipelago).

C. d. marshalli (Iredale, 1946) - extreme N Queensland.

C. d. nucleayana E. P. Ramsay, 1874 - NE Queensland.

C. d. coxeni Gould, 1867 - SE Queensland and NE New South Wales.

Descriptive notes. 13-16 cm; 25-56 g. Green above, yellowish green below; crown red shading to orange then green on hindcrown; area in front of eye pale blue shading above it to green; area from base of bill and chin back to ear-coverts red, bordered dark blue on lower ear-coverts; sides of breast and flanks yellow; some red on inner part of wing; flight-feathers dark bluish, with yellowish white band on underside of secondaries. Female has lower cheeks buffy pink. Immature like female. Race *coccineifrons* darker, more orange on crown; *aruensis* with blue on ear-coverts to chin, greenish tinge to blue in front of eye, little or

ange on crown; *virago* little blue on face; *inseparabilis* no blue or buff on cheeks; *marshalli* similar to *aruensis* but lacks green tinge; *macleayana* lacks red on lores, crown green; *coxeni* has virtually no red on crown, just a blue forehead, and broken orange-red-green facial pattern.

Habitat. Lowland and montane forest and edge, riverine and more open woodland, tall second growth, partly cleared areas with clumps of trees, mangroves, sometimes entering parks and gardens. Generally up to 1600 m, occasionally as high as 2000 m.

Food and Feeding. Fruits, particularly figs such as *Ficus eugenioides*, *F. destruans*, *F. hispida*, *F. ehretii*, *F. macrophylla* and *F. watkinsiana* (seeds rather than flesh being taken), but also e.g. *Croton*, *Elaeocarpus grandis*, *Trema orientalis*, *Alphitonia whitei*, berries, seeds, nectar (e.g. *Grevillea robusta*), bark or fungal growths, and insects.

Breeding. Variably recorded: Mar-May in New Guinea, but extending, e.g. breeding condition female at hole in Jun, or recurring later, e.g. Nov; Aug-Nov in Australia. Nest in hollow of high,

often emergent tree, or in rotten tree-trunk or dead limb. Eggs 2; in captivity, incubation period 18 days, nestling period 52 days or more.

Movements. Apparently nomadic at least in parts of range.

Status and Conservation. Not globally threatened. Race *coxeni* on CITES I; other forms on CITES II. Locally common, especially in lower reaches of altitudinal range; general sense of rarity probably related to difficulty of detection. Only race *coxeni* gives cause for concern owing to loss and fragmentation of habitat, although much of its breeding habitat is now in reserves.

Bibliography. Beehler *et al.* (1986), Blakers *et al.* (1984), Bourke & Austin (1947), Coates (1985), Diamond (1972a), Forshaw (1967, 1979, 1981a, 1981b), Garnett (1993), Gill (1970), Hiaso *et al.* (1994), Holmes (1990), Low (1994b), Mack & Wright (1996), Martindale (1985), Mayr & Gilliard (1954), McWhirter (1986a), Neufeld (1995), Rand & Gilliard (1967), Ripley (1964), Romer (1994), Spittall (1991), Symons (1993).

Genus *PSITTACULIROSTRIS*

J. E. & G. R. Gray, 1859

66. Large Fig-parrot

Psittaculirostris desmarestii

French: Psittacule de Desmarest **Spanish:** Lorito de Desmarest
German: Buntbrust-Zwergpapagei
Other common names: Golden-headed Fig-parrot, Desmarest's Fig-parrot

Taxonomy. *Psittacus Desmarestii* Desmarest, 1826. Manokwari, New Guinea.
Genus sometimes lumped into *Cyclopsitta* (or *Opopsitta*). Six subspecies recognized.
Subspecies and Distribution.

P. d. blythii (Wallace, 1864) - Misool, W Papuan Is.
P. d. occidentalis (Salvadori, 1875) - Batanta, Salawati and W Vogelkop.
P. d. desmarestii (Desmarest, 1826) - E Vogelkop.
P. d. intermedia (van Oort, 1909) - Onin Peninsula, Irian Jaya.
P. d. godmani (Ogilvie-Grant, 1911) - S New Guinea from SE Irian Jaya to R Fly.
P. d. cervicalis (Salvadori & D'Albertis, 1875) - R Fly E to extreme E New Guinea.

Descriptive notes. 18 cm; 108-126 g. Forehead red shading to orange on crown and nape; lores to below eye blue; face light green bordered by light blue breastband and broken orange-brown band; underparts yellowish green; back, wings and tail dull green, with innermost tertials edged orange; underwing bar pale yellow. Immature has crown dull yellow. Race *intermedia* has more orange crown; *occidentalis* deep yellow face; *blythii* like *occidentalis* but face brighter with no blue; *godmani* like *blythii* with yellow ear-covert feathers elongated, crown and nape orange-red with yellow band on hindneck; *cervicalis* similar with blue band on hindneck, darker blue band across breast.

Habitat. Lowland and low hill forest, partly cleared areas, groves of casuarinas, occasionally open savanna, extending rarely up to 1650 m.

Food and Feeding. Seeds of figs and partial consumption of hard pericarp of fig noted; and use of a fig species in which the fruit grows in clusters from the trunk.

Breeding. Female in breeding condition in Jul, male in Aug, and colony of nests being attended in Sept. Nest in cavity high in trunk or branch of large old tree.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Conflicting reports exist of its general abundance, but it is generally uncommon and apparently local, and intolerant of serious habitat degradation. A total of 4475 birds were exported from Indonesia in the years 1985-1990, a level of trade which has been judged possibly to place the Irian Jaya populations at risk; commercial importation of the species into the EC from Indonesia was prohibited in Nov 1987.

Bibliography. Andrew (1992), Anon. (1993, 1994a), Beehler (1982), Beehler *et al.* (1986), Coates (1985), Diamond (1972a), Gregory (1995a, 1995b), Hoogerwerf (1971), Mayr & Meyer de Schauensee (1939a), Neufeld (1995), Rand (1942a), Rand & Gilliard (1967), Rothschild (1920), Sweeney (1993c), Tubb (1945), Wiseman (1988).

67. Edwards's Fig-parrot

Psittaculirostris edwardsii

French: Psittacule d'Edwards **German:** Edwardszwergpapagei **Spanish:** Lorito de Edwards

Taxonomy. *Cyclopsittacus Edwardsii* Oustalet, 1885, Kafu, New Guinea.
Genus sometimes lumped into *Cyclopsitta* (or *Opopsitta*). Monotypic.

Distribution. NC & NE New Guinea from Humboldt Bay E to Huon Peninsula.

Descriptive notes. 18 cm; 105 g. Forehead and mid-crown bright green, isolated by broad black line through eye to hindcrown and nape; elongated feathers of anterior face red, posterior (ear-coverts) yellow with some pale blue; broad band on upper breast blue-black; lower breast to belly red, with green flanks, thighs, vent and undertail-coverts; back, wings and tail dull green, with innermost tertials edged orange-red; underwing bar yellow. Female lacks red on breast. Immature like female with anterior face yellow.

Habitat. Lowland and hill forest and edge, also partly cleared land.

Food and Feeding. Figs are the only certainly recorded food; other reports are of fruits of casuarinas and other trees; birds sometimes feeding in large flocks.

Breeding. Apparent nest-site occupation observed, Jan-May; juvenile collected in Jul; courtship and nest prospecting in Oct. Presumed nest-sites were small holes high in tall trees.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Locally common to very common, with as many as 400 recorded in a foraging flock. A total of 2851 birds were exported by Indonesia in the period 1985-1990, a level of trade not judged to be

prejudicial to the security of this species; however, its commercial importation into the EC from Indonesia was prohibited in Nov 1987.

Bibliography. Andrew (1992), Anon. (1993), Bailey (1992a), Barnicoat (1995a), Beehler *et al.* (1986), Coates (1985), Diamond (1972a), Draffan (1977), Greensmith (1975), Neufeld (1995), Pearson (1975b), Rand & Gilliard (1967), Ripley (1964), Sujatnika *et al.* (1995).

68. Salvadori's Fig-parrot

Psittaculirostris salvadorii

French: Psittacule de Salvadori **German:** Salvadorizwergpapagei **Spanish:** Lorito de Salvadori
Other common names: Whiskered Fig-parrot

Taxonomy. *Cyclopsittacus Salvadorii* Oustalet, 1880, north coast of New Guinea between long. 136°30' and 137° E.

Genus sometimes lumped into *Cyclopsitta* (or *Opopsitta*). Monotypic.

Distribution. NW New Guinea from E shores of Geelvink Bay E to Cyclops Mts.

Descriptive notes. 19 cm; 118 g. Forehead bluish green shading to bright green crown, yellow on nape; elongated facial feathers golden yellow, blue behind eye; undersides yellowish green except for broad orange-red patch on breast; back, wings and tail dull green, with innermost tertials edged orange. Female has bluish crown, greenish yellow face, pale blue patch on breast. Immature duller than female.

Habitat. Lowland forest and edge, up to 400 m.

Food and Feeding. Seen attending a fruiting fig tree.

Breeding. Record of possible nest-site prospecting in hole in tree.

Movements. No information.

Status and Conservation. **VULNERABLE.** CITES II. A BirdLife "restricted-range" species. Locally common and parts of range are remote and inaccessible, but extensive logging and land clearance in the region, owing to Indonesia's transmigration policy, coupled with extensive trapping for the cagebird trade, are judged to be causing a rapid and substantial decline in numbers. However, a total of only 1582 birds was exported from Indonesia in the period 1985-1990, which was not judged to prejudice the security of the species; nevertheless, its commercial importation into the EC from Indonesia was prohibited in Jul 1987.

Bibliography. Andrew (1992), Anon. (1993), Beehler *et al.* (1986), Collar & Andrew (1988), Collar *et al.* (1994), Courtney (1997b), Diamond, J.M. (1985), Leli (1991), Neufeld (1995), Rand & Gilliard (1967), Smith (1977c), Sujatnika *et al.* (1995), Sweeney (1997c).

Genus *BOLBOPSITTACUS* Salvadori, 1891

69. Guaiabero

Bolbopsittacus lunulatus

French: Perruche lunulée **German:** Stummelschwanzpapagei **Spanish:** Lorito Guaiabero

Taxonomy. *Psittacus lunulatus* Scopoli, 1786, Luzon.
Four subspecies recognized.

Subspecies and Distribution.

B. l. lunulatus (Scopoli, 1786) - Luzon, N Philippines.
B. l. callainipictus Parkes, 1971 - Samar, EC Philippines.
B. l. intermedius Salvadori, 1891 - Leyte and Panaon, EC Philippines.
B. l. mindanensis (Steere, 1890) - Mindanao, SE Philippines.

Descriptive notes. 15 cm; 62-77 g. Green above, yellowish green below and on rump and uppertail-coverts; bill bluish grey; face and throat pale blue; narrow pale blue collar; bend of wing blue; pale yellow band across undersides of secondaries. Female has pale blue only on throat, lores and cheeks; has yellow collar and yellowish rump, both with small but noticeable black crescent markings. Immature like female, bill paler. Races differ mainly in general tone of coloration, and in tone and extent of blue on head and narrow collar.

Habitat. Forest and forest edge, secondary growth, clearings with scattered trees, orchards

and mangroves.

Food and Feeding. Fig seeds and fruit, fruits of vines and cultivated trees including guava, from which its name derives; forages along vines and limbs of trees. Generally found feeding below 1000 m.

Breeding. Starting to reach breeding condition in Mar.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Usually considered fairly common throughout fairly limited range; regularly recorded at Angat Watershed Forest, in area of reservoir to serve Manila.

Bibliography. Amadon & Jewett (1946), Danielsen *et al.* (1994), Delacour & Mayr (1946), Dickinson *et al.* (1991), DuPont (1971), Gilliard (1950b), Goodman & Gonzales (1990), Hachisuka (1934), McGregor (1909-1910), Parkes (1971b), Rand & Rabor (1960), Sargeant (1992), Smith, G.A. (1981), Sweeney (1994a, 1995c), Wheatley (1996).

Tribe PLATYCERCINI

Genus *PROSOPEIA* Bonaparte, 1854

70. Crimson Shining-parrot

Prosopeia splendens

French: Perruche écarlate **German:** Fidschisittich **Spanish:** Papagayo Escarlata
Other common names: Crimson Musk-parrot

Taxonomy. *Platycercus splendens* Peale, 1848, Peale's River, Viti Levu, Fiji Islands. Usually considered conspecific with *P. tabuensis*, but may be closer to *P. personata*. Monotypic.
Distribution. SW Fiji, on Kadavu and Ono. Introduced to Viti Levu.

Descriptive notes. 45 cm. Very similar to *P. tabuensis* but head and underparts bright crimson, with broad blue collar across upper mantle. Female has smaller bill. Immature similar to adult.

Habitat. Mangrove, forest at all elevations, edges of villages.

Food and Feeding. No information.

Breeding. No information.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. On Kadavu numerous in 1970 in

Gasele Forest, and elsewhere widespread; but apparently very scarce and declining on Viti Levu, where only found near villages.

Bibliography. Blackburn (1971), Clunie (1984), Collar *et al.* (1994), Holyoak (1979), Low (1994b), Mayr (1945b), Pratt *et al.* (1987), Rinke (1989a), Watling (1982a).

71. Masked Shining-parrot

Prosopeia personata

French: Perruche masquée **German:** Maskensittich **Spanish:** Papagayo Enmascarado
Other common names: Yellow-breasted Shining-parrot, Masked Musk-parrot

Taxonomy. *Coracopsis ? personata* G. R. Gray, 1848, New Guinea? Monotypic.

Distribution. SW Fiji, on Viti Levu; also early reports from adjacent Ovalau and Mbau.

Descriptive notes. 47 cm. Bright green, with black forehead and area on face round eye to chin, broad yellow rough-edged patch from upper breast to vent, where turns to red; outer webs of primaries deep blue; tail below brownish black. Female has smaller bill. Immature has paler bill.

Habitat. Mature forest, secondary growth, edges of villages, mangroves, subsistence gardens, from coasts up to 1200 m.

Food and Feeding. Seeds and fruits including wild figs; also cultivated fruits such as *Inocarpus fagiferus*, guavas and mangoes; flowers of banana palms; caterpillars; and rip-

ening grain.

Breeding. Jul-Sept. Nest in hole in tree. Eggs 2, although locals have reported 3-4 young in family parties.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. Fairly common, and very frequent in the Nausori Highlands in 1970, but some concern remains over the impact of fragmentation of habitat with continuing forest clearance.

Bibliography. Blackburn (1971), Clunie (1984), Collar *et al.* (1994), Dahl (1986), Holyoak (1979), Low (1994b), Mayr (1945b), Pratt *et al.* (1987), Rinke (1989a), Watling (1982a), Wood & Wetmore (1926).

72. Red Shining-parrot

Prosopeia tabuensis

French: Perruche pompadour **German:** Pompadoursittich **Spanish:** Papagayo Granate
Other common names: Red-breasted Shining-parrot, Red Musk-parrot

Taxonomy. *Psittacus tabuensis* J. F. Gmelin, 1788, Tonga Tabu, Tonga Islands.

Sometimes considered conspecific with *P. splendens*, but latter may be closer to *P. personata*. Nominate race often restricted to birds of Gau (Fiji) and Tonga, with those of Koro placed in *koroensis* and remainder in *atrogularis*, on basis of presence and extent of blue nuchal collar and maroon feather fringes on rump and uppertail-coverts, but these characters now known to be variable within populations; situation somewhat confused, especially due to probable mixtures resulting from introductions. Two subspecies currently recognized.

Subspecies and Distribution.

P. t. tabuensis (J. F. Gmelin, 1788) - Vanua Levu, Kioa, Koro and Gau in Fiji, and 'Eua in Tonga; formerly Tongatapu in Tonga, where the few birds now present are escapes.

P. t. taviunensis (E. L. Layard, 1876) - Taveuni and Ngamea (Qamea), Fiji.

Descriptive notes. 45 cm; mean 280 g. Forehead and lores black shading to deep maroon on mid-crown, nape and face, and to dull red on underparts; blue nuchal collar varies from broad to narrow to absent; outer wing-coverts, primaries and edges of tail deep blue; rest of uppersides and upper tail oil green, sometimes with varying amounts of dark maroon edging to feathers of rump and upper row of uppertail-coverts; tail below blackish brown. Female has smaller bill. Immature has paler bill. Race *taviunensis* invariably lacks blue hindneck and has shorter wings.

Habitat. Chiefly forest (with *Myristica hypargyrea* dominant, 'Eua) including mangroves and secondary scrub, but also commonly in village gardens and outskirts, and on Ngau throughout agricultural areas; altitudinal restriction mainly to above 380 m, Taveuni, presumably only owing to conversion of lower areas to coconuts, etc. On 'Eua, distribution exactly coincident with forest and forest patches, with only occasional records from plantations and low secondary growth.

Food and Feeding. Over 30 foodplants identified, 'Eua, where top ten food-plants in descending order are *Myristica hypargyrea*, *Psidium guajava*, *Inocarpus fagiferus*, *Calophyllum neo-eudicum*, *Rhus taitensis*, *Elattostachys falcata*, *Carica papaya*, *Malisia*, *Pleignium timoriense* and *Melodinus vitense*; elsewhere small wild bananas seen taken, also apparently insect larvae extracted from rotting wood. On 'Eua about 20% of feeding observations have involved introduced plants, but claims of crop damage have been exaggerated.

Breeding. May-Oct. Nest in hollow branch or hole in tree, once in the branch of large kau (*Burckellia richii*), once at 1750 m; on 'Eua the chief tree used is *Rhus taitensis* followed by *Elattostachys falcata* and *Laportea harveyi*. Eggs 2-3; incubation period 24 days; fledging c. 7 weeks.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Common (but not flock-forming) in remaining forest, 'Eua (Tonga), with 500-1500 birds estimated, but habitat loss is rapid and a major decline towards extinction is predicted there; introduction to Tofua has been proposed. Habitat loss was the factor that caused its disappearance from Tongatapu, the type locality. Common on Taveuni, 1973. Apparently thriving, Ngau.

Bibliography. Blackburn (1971), Clunie (1984), Dahl (1986), Hay (1986), Holyoak (1979), Lever (1987), Low (1994b), Mayr (1945b), Pratt *et al.* (1987), Rinke (1986a, 1986b, 1987, 1988a, 1988b, 1989a, 1989b, 1993), Stevens (1996), Watling (1982a, 1985).

Genus *EUNYMPHICUS* J. L. Peters, 1937

73. Horned Parakeet

Eunymphicus cornutus

French: Perruche cornue **German:** Hornsittich **Spanish:** Perico Cornudo

Taxonomy. *Psittacus cornutus* J. F. Gmelin, 1788, New Caledonia.

On occasions has been lumped into genus *Cyanoramphus*. Races may merit treatment as two distinct species. Two subspecies recognized.

Subspecies and Distribution.

E. c. cornutus (J. F. Gmelin, 1788) - New Caledonia.

E. c. uvaensis (E. L. & E. L. C. Layard, 1882) - Ouvea (Loyalty Is).

Descriptive notes. 32 cm. Generally green, more yellowish on underparts, with rump, ear-coverts and nape greenish yellow; forehead to mid-crown red with several red-tipped black crest-feathers; front of face around eye to chin smudgily black; outer webs of primaries violet blue; tail distally shaded violet, lateral feathers violet tipped whitish. Immature greener, with crown mostly black. Race *uvaensis* lacks yellow tinging on head, with more crest feathers, all green, and red more restricted on crown.

Habitat. Forests, notably *Agathis-Araucaria* dominated, and general wooded areas, but avoiding coconut plantations and coastal areas.

Food and Feeding. Berries of vines, seeds of various trees and shrubs, notably "penubree tree", *Agathis lanceolata* and *Lantana camara*. On Ouvea, food includes flowers and fruits of "forest" trees such as *Syzygium*, *Ficus* and *Mimusops*, and adjacent trees and plants of cultivated areas such as *Carica papaya*, *Capsicum*, *Passiflora*, *Psidium*, *Solanum* and *Muesia novo-caledonica*; bark of *Hibiscus tiliaceus* also eaten.

Breeding. Sept-Mar. Nest in hole in dead or living tree, species including (on New Caledonia) *Metrosideros* and (Ouvea) *Syzygium*, *Mimusops*, *Dysoxylum*, *Intsia* and *Ficus*. Eggs 2-4, although usually only 2 young are reared; in captivity, incubation lasts 21-22 days, nestling period 5-6 weeks.

Movements. Sedentary; when birds from Ouvea were introduced to island of Lifou in an attempt to establish a new population, they reportedly flew back.

Status and Conservation. **VULNERABLE.** CITES II. A BirdLife "restricted-range" species. Nominate *cornutus* has declined substantially since the 1880's owing to habitat loss and the cagebird trade and may now number several thousand individuals. Following habitat conversion to plantations and the effects of overtrapping, race *uvaensis* was believed to number 100-200 birds in the early 1990's, but numbers were estimated at 617±379 birds in Dec 1993; possibly the most important factor here is the absence of predatory rats on the island, but 30-50 birds are captured annually for the pet trade, and this must be brought under control.

Bibliography. Bregulla (1993), Bruce (1978), Collar *et al.* (1994), Delacour (1966), Hahn (1993), Hannecart (1988), Hannecart & Létocart (1983), Hay (1986), King (1978/79), Low (1994b), Mayr (1945b), Quinque (1980),

Rinke (1997a), Robinet (1996), Robinet, Barre & Silas (1996), Robinet, Beugnet *et al.* (1995), Vincent (1967), Vriends (1979), Warner (1947).

Genus *CYANORAMPHUS* Bonaparte, 1854

74. Antipodes Parakeet

Cyanoramphus unicolor

French: Perruche des Antipodes **German:** Einfarbsittich **Spanish:** Perico de las Antipodas
Other common names: Antipodes Green Parakeet

Taxonomy. *Platyercus unicolor* Lear, 1831, Antipodes Island. Monotypic.

Distribution. Antipodes Is.

Descriptive notes. 30 cm. Green, bright emerald on forehead and face, olive on rest of plumage, yellow below; outer webs of primaries purplish blue, tail margined yellow. Immature undescribed.

Habitat. Tall dense *Poa litorosa* tussocks, especially on coastal slopes and along watercourses, whereas sympatric *C. novaezelandiae* tended to occupy more open terrain.

Food and Feeding. *Poa* and *Carex* leaves comprised 70% of records, with seeds (13%), berries, flowers and other vegetation (10%), and carrion of penguins and petrels (6%).

Breeding. Oct-Jan. Nest in well-drained bur-

row, 1 m or more long, excavated in fibrous peat beneath vegetation or in thick matted bases of tall tussocks. Clutch size unknown, but 1-3 fledged young recorded.

Movements. Sedentary.

Status and Conservation. VULNERABLE. CITES II. A BirdLife "restricted-range" species. Generally common, with a total population estimated at 2000-3000 birds. The only threat to this species is the accidental introduction of some predator (rats or cats) from a fishing or other passing vessel; although once a remote possibility, increased fishing pressure in waters around the (uninhabited) Antipodes has greatly heightened the chances of such an event.

Bibliography. Anon. (1996a), Chambers (1989), Collar & Andrew (1988), Collar *et al.* (1994), Falla *et al.* (1981), Fingland (1994), Goudswaard (1988), Greenway, J.C. (1967), Oliver (1974), Robertson (1985), Taylor (1975, 1985), Warham & Bell (1979), Williams & Given (1981).

75. Red-fronted Parakeet

Cyanoramphus novaezelandiae

French: Perruche de Sparman **German:** Ziegensittich **Spanish:** Perico Maorí Cabecirrojo
Other common names: Red-crowned Parakeet; Norfolk Parakeet (*cookii*); New Caledonian Parakeet (*saisseti*)

Taxonomy. *Psittacus Novae Zelandiae* Sparman, 1787, Dusky Sound, South Island.

Races *cookii* and *saisseti* sometimes considered separate species. Races *erythrotis* of Macquarie I and *subflavescens* of Lord Howe I extinct. Six extant subspecies recognized.

Subspecies and Distribution.

C. n. saisseti J. Verreaux & Des Murs, 1860 - New Caledonia.

C. n. cookii (G. R. Gray, 1859) - Norfolk I.

C. n. cyanurus Salvadori, 1891 - Kermadec Is.

C. n. novaezelandiae (Sparman, 1787) - New Zealand, on North I, South I, Stewart I, Auckland Is and many offshore islands.

C. n. chathamensis Oliver, 1930 - Chatham Is.

C. n. hochstetteri (Reischek, 1889) - Antipodes Is.

Descriptive notes. 27 cm; 50-113 g. Green, more yellowish below; frontal band through and behind eye, and forehead to mid-crown, red; patch each side of rump red; outer webs of primaries dark blue. Immature has less red on head, shorter tail. Race *cyanurus* bluer on flight-feathers with greenish blue tail; *chathamensis* like nominate but face bright emerald; *hochstetteri* larger and more yellowish, red markings more orange; *cookii* like nominate but larger; *saisseti* like nominate but more yellowish, and red lighter and brighter.

Habitat. Originally throughout native forests at all altitudes, now chiefly in remaining forest at low altitudes than *C. auriceps*, but in forest, scrubland and open areas on smaller islands. On the treeless Antipodes birds are terrestrial, occupying more open areas and low coastal vegetation than sympatric *C. unicolor*.

Food and Feeding. Much seasonal variation in diet, with buds and blossoms being consumed in spring, fruit in summer and seeds in autumn, with seeds and fruit together in winter. On Poor Knights Is birds took flowers of *Metrosideros excelsa* in Oct-Nov, seeds of *Leptocarpus*, *Cortaderia richardii*, *Coprosma macrocarpa* and *Macropiper exulans* in Jan, seeds of *Pittosporum crassifolium* in Feb-May and Aug. On Antipodes Is the main food was seeds of *Poa litorosa* grass and *Carex appressa* sedge (55% of records), with flowers (20%), berries (9%), leaves and buds (8%) and invertebrates (5%). On Norfolk I seeds and blossoms of *Baloghia lucida* and blossoms of *Lagunaria patersonia* preferred, supplemented by fruits of various exotic shrubs and trees, and leaf shoots and seeds of Norfolk Island pines (*Araucaria heterophylla*). In autumn on Rangitira (South-east) I, Chathams, seeds of *Plagianthus regius* and *Hebe dieffenbachii* and fruits of *Myoporum laetum* were most important (60% records). Seeds of casuarinas important in New Caledonia.

Breeding. Nov-Jan in New Caledonia, but any time of year elsewhere in N; Oct-Dec in S. Nest in hole in tree or cliff bank, in natural fissure in rock, in burrow in ground or matted vegetation; in Antipodes, birds make tunnels in the crowns of tall tussocks or clumps of ferns. Eggs 5-9; incubation lasts c. 20 days; nestling period 5-6 weeks. Males may have higher survival rate than females.

Movements. In early days of human settlement irruptive behaviour was noted at certain localities, and there still may be some seasonal wandering. Birds regularly commute between islands, whether mainland to offshore or offshore to offshore; dispersers from Macaulay in the Kermadecs occasionally cover the 40 km to Curtis I.

Status and Conservation. Not globally threatened. Race *cookii* has been treated as a full species and accorded Critically Endangered status. CITES I. Greatly reduced from historical levels on two main islands, but still common on Stewart and many offshore islands. Antipodes (an estimated 4000-5000 individuals in 1978) and Auckland Is. On Chathams numbers greatly reduced by habitat loss and predation on two main islands, but abundant on the small Rangitira, and numbers controlled on Mangere and Little Mangere as part of conservation efforts for *C. forbesi*. On Kermadec Is introduced predators wiped out Raoul I population 150 years ago, but over 10,000 birds survived in 1980 on Macaulay following goat eradication in 1960's, with small numbers on other islands. The species is uncommon on New Caledonia. Norfolk I population (race *cookii*) numbered 40 birds (with 13 in captivity) in 1991, having suffered from hunting, habitat destruction, predation by rats and nest-site competition from introduced *Platyercus elegans*, European Starlings (*Sturnus vulgaris*) and honeybees, but now starting to recoup following years of active management. Translocation of birds from Norfolk to Lord Howe I has been urged, given that fewer threats exist there and extinction was reputedly caused by human persecution; translocation at least to Philip I likely. Extinction on Macquarie attributed to predation by feral cats following the reduction of habitat by rabbits.

Bibliography. Bellingham (1987), Bregulla (1993), Butler (1986), Chambers (1989), Christidis & Boles (1994), Collar *et al.* (1994), Dawe (1979), Falla *et al.* (1981), Fingland (1994), Forshaw (1981a, 1981b, 1981c), Freeman (1994), Garnett (1993), Greene (1989a), Greenway, J.C. (1967), Greenwood (1991), Hannecart & Létocart (1980), Hay (1986), Hermes (1985), Hicks & Greenwood (1990), King (1978/79), Kinsky (1970), Low (1994b), MacMillan (1990), Merton (1970), Nilsson *et al.* (1994), Nixon (1982, 1994), O'Donnell & Dilks (1993), Porter (1939), Remington (1987), Robertson (1985), Sagar (1988), Schmidt (1997), Schodde *et al.* (1983), Soper (1976), Taylor (1975, 1979, 1985), Triggs & Daugherty (1996), Veitch (1979), Vriends (1979), Warham & Bell (1979), Williams (1975).

76. Yellow-fronted Parakeet

Cyanoramphus auriceps

French: Perruche à tête d'or **German:** Springsittich **Spanish:** Perico Maorí Cabecigualdo
Other common names: Yellow-crowned Parakeet, Yellow-fronted Kakariki

Taxonomy. *Psittacus auriceps* Kuhl, 1820, New Holland = South Island, New Zealand.

Normally considered to include *C. forbesi* and *C. malherbi* as a race and a variant respectively, but these forms perhaps better treated as separate species. Monotypic.

Distribution. New Zealand area, on North I, South I, Stewart I and Auckland Is, and several small offshore islands.

Descriptive notes. 23 cm. Very similar to *C. novaezelandiae* but head simply with red frontal band extending to eyes, backed by yellow crown.

Habitat. Prefers mixed *Nothofagus*-*Podocarpus* forest, usually at higher altitudes than *C. novaezelandiae*, and, where the two occur together on small islands, prefers taller unbroken forest and scrub, with *C. novaezelandiae* occupying more open areas and lower vegetation.

Food and Feeding. Seeds including grass seeds, many kinds of berry, shoots, buds, flowers and invertebrates, on main islands taken in

trees, but on predator-free islands often from the ground; seeds of *Pseudopanax*, *Leptospermum*, thistles and flowers of *Senecio*, *Hymenanthera*, *Phormium* and *Coprosma*; seeds of *Ixerbia* and fruit of *Dysoxylum* also noted. Invertebrates important in diet, including scale insects *Ultracoelostoma assimile* and caterpillars of *Heliothis vibratrix*.

Breeding. Main period Oct-Dec, but nesting recorded in all months except May and Jun. Nest in hollow limbs or holes in trunks, often dead or decaying stumps. Eggs 5-9.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. Formerly widespread and common, now confined to larger tracts of remaining native forest, with numbers varying from rare to locally fairly common, but essentially now stable following steady increases since 1950. However, felling of native lowland forest for exotic pine plantations continues to pose a threat. Common on Stewart, the Auckland and other islands, where introduced predators, in particular rats, are absent.

Bibliography. Butler (1986), Chambers (1989), Falla *et al.* (1981), Fingland (1994), Greene (1989a), Greenway, J.C. (1967), Kinsky (1970), Low (1994b), Ogle (1981), Oliver (1974), Palser (1991), Robertson (1985), Soper (1976), St. Paul (1977), Taylor (1975, 1985), Triggs & Daugherty (1996), Veitch (1979), Vriends (1979).

77. Chatham Parakeet

Cyanoramphus forbesi

French: Perruche des Chatham **German:** Chathamsittich **Spanish:** Perico de las Chatham
Other common names: Chatham Yellow-fronted/Forbe's Parakeet

Taxonomy. *Cyanoramphus* [sic] *forbesi* Rothschild, 1893, Chatham Islands.

Since 1930 commonly treated as a race of *C. auriceps*, but genetic differences considerable; clearly, however, the two are very closely related. Monotypic.

Distribution. Chatham Is, on Mangere I and Little Mangere I, and formerly also Pitt I.

Descriptive notes. 26 cm. Extremely similar to *C. auriceps*, but larger and brighter, with more yellowish underparts, red frontal band not extending to eyes, sides of face emerald green and outer webs of flight-feathers greenish blue.

Habitat. Dense unbroken forest or scrub.

Food and Feeding. In spring, Oct-Nov, main foods are invertebrates, flowers and seeds, while in autumn, Mar-May, more leaves and seeds are eaten.

Breeding. Oct-Mar. Nest in hollow limbs or holes in trunks, often dead or decaying stumps.

Movements. Sedentary, with pairs generally occupying territories year-round.

Status and Conservation. ENDANGERED. CITES I (where treated as *C. auriceps forbesi*). Highly threatened, although the population is slowly increasing through a habitat management and competitor control programme. In 1938 there were over 100 birds, in 1968 20-30, and a decade later the species was confined to 4 ha of bush at the summit of Little Mangere I; however, reforestation of Mangere has allowed a slow recolonization. Native *C. novaezelandiae* benefited from forest clearance and began hybridizing with

present species, but with intervention there were 40 pure individuals of present species on Mangere in 1982, when about 16 were judged to survive in still-deteriorating habitat on Little Mangere. In 1970's and 1980's evidence for either a remnant population on or a recolonization of the main Chatham I emerged, but may have only involved one or two birds.

Bibliography. Ellis (1975), Erritzoe (1993), Flack (1976), Fleming (1939), Freeman (1994), Greene (1989b), Johnstone (1985), King (1978/79), Kinsky (1970), Low (1994b), Melville (1984), Nixon (1982, 1994), Taylor (1975, 1985), Triggs & Daugherty (1996).

78. Malherbe's Parakeet

Cyanoramphus malherbi

French: Perruche de Malherbe **German:** Malherbesittich **Spanish:** Perico Maorí Montano
Other common names: Orange-fronted Parakeet(!)

Taxonomy. *Cyanoramphus Malherbi* Souancé, 1857, South Island, New Zealand.

Since 1974 the view that this is a colour morph of *C. auriceps* has gained wide acceptance, but very recent evidence suggests assortative mating among the few surviving wild birds, so specific status should perhaps be retained. Monotypic.

Distribution. Formerly scattered through most of New Zealand; now confined to N South I.

Descriptive notes. 20 cm. Very similar to *C. auriceps* but frontal band orange, crown pale yellow, patches either side of rump orange. Immature almost lacks frontal band.

Habitat. Fringes of *Nothofagus* forest, in one area being found breeding only at 600-900 m in forest of *N. fusca*, but with preference for areas bordering stands of *N. solandri*; in past reported from sea-level to subalpine scrublands.

Food and Feeding. Scale insects, flower and leaf buds, flowers, young leaves, berries and seeds.

Breeding. Oct. Nest in hole in living or dead tree. Eggs 3.

Movements. No information.

Status and Conservation. CRITICALLY ENDANGERED. CITES II (where included in *C. auriceps*). Species at great risk of extinction, given that its population could well be under 250 individuals and declining. Captive breeding involving mixed pairs of present species and *C. auriceps* needs to be reconsidered.

Bibliography. Chambers (1989), Ellis (1975), Falla *et al.* (1981), Fleming (1980), Greene (1989a), Greenway, J.C. (1967), Harrison (1970), Heatherbell (1992), Holyoak (1974a), King (1978/79), Kinsky (1970), Low (1994b), Nixon (1981), Oliver (1974), Read & McClelland (1984), Robertson (1985), Sibson (1982), Taylor (1975, 1985), Taylor *et al.* (1986), Triggs & Daugherty (1996).

Genus *PURPUREICEPHALUS*

Bonaparte, 1854

79. Red-capped Parrot

Purpureicephalus spurius

French: Perruche à tête pourpre **German:** Kappensittich **Spanish:** Perico Capelo
Other common names: Pileated Parakeet

Taxonomy. *Psittacus spurius* Kuhl, 1820, Albany, south-western Australia. Sometimes placed in genus *Platycercus*. Monotypic.

Distribution. Extreme SW Australia, mostly within 100 km of coast.

Descriptive notes. 36 cm; 98-156 g. Entire crown crimson, face and ear-coverts yellowish green; underparts purple, with flanks, thighs and undertail-coverts red; nape, mantle and wing-coverts green, flight-feathers dark, with underwing-coverts and outer webs of primaries dull blue; rump and uppertail-coverts yellowish green; tail green, distally darker, lateral feathers pale blue tipped whitish. Female duller, with wing stripe on underwing; flanks and undertail-coverts with green. Immature has green head, dull russet breast and belly.

Habitat. Marri *Eucalyptus calophylla* forest

and trees in pristine and altered landscapes including farmland, roadsides and watercourses, also visiting parkland and orchards.

Food and Feeding. Seeds of marri and other eucalypts, notably jarra *E. marginata* and *E. cornuta*, also those of *Grevillea*, *Hakea*, *Casuarina*, *Xylomelum*, *Agonis* and grasses, especially *Avena fatua*; plus blossoms (several eucalypts), leaf buds and insects and their larvae, in particular psyllid lerps. Sometimes damages apples, pears and citrus fruits.

Breeding. Aug-Dec. Nest in hollow limb or hole in tree, commonly high in jarra, marri or wandoo (*E. wandoo*). Eggs 4-7; incubation lasts c. 20 days; nestling period c. 5 weeks.

Movements. Adults are mainly sedentary but fluctuations in local numbers of immatures occur according to food availability; also nomadism at dry edges of range.

Status and Conservation. Not globally threatened, CITES II. Fairly common, sometimes entering suburbs of Perth. While marri, regarded as a weed species, may actually have spread following human occupation of SW Australia, thus benefiting this parrot, poor regeneration of nest-trees is a long-term cause for concern, and the restricted range of the species compounds the situation. In two shires of Western Australia there are open seasons when birds may be killed to reduce orchard damage.

Bibliography. Blakers *et al.* (1984), Cain (1955), Cook (1980), Forshaw (1981b), Jenkins (1969), Lindsey, T.R. (1992), Long (1984, 1985), Macdonald (1988), Mawson & Long (1994), Pizzey & Doyle (1980), Saunders & Ingram (1995), Schodde & Tidemann (1986), Simpson & Day (1996), Stoneman *et al.* (1997), Tronson & Tronson (1987), Vriends (1979).

Genus *BARNARDIUS* Bonaparte, 1854

80. Port Lincoln Ringneck

Barnardius zonarius

French: Perruche à collier jaune **German:** Ringsittich **Spanish:** Perico de Port Lincoln
Other common names: Ringneck Parrot, Australian/Western Ringneck; Twenty-eight Parrot (*semitorquatus*)

Taxonomy. *Psittacus zonarius* Shaw, 1805, Port Lincoln, South Australia.

Genus sometimes combined into *Platycercus*. Forms a parapatric species pair with *B. barnardi*, with which often considered conspecific. Three subspecies recognized.

Subspecies and Distribution.

B. z. semitorquatus (Quoy & Gaimard, 1830) - extreme W Western Australia.

B. z. occidentalis (North, 1893) - SW Western Australia.

B. z. zonarius (Shaw, 1805) - Western Australia E to SC Northern Territory and SC South Australia.

Feral (presumably race *zonarius*) around Melbourne, Victoria.

Descriptive notes. 38 cm; 121-200 g. Head dull blue-black sometimes with red frontal band; yellow collar broken at throat; breast, mantle, back and wings green hazed pale blue, with fuller pale blue edging on median and outer secondary coverts, primaries blackish; belly yellow shading to yellowish green on vent and undertail-coverts; rump and tail blue-green, latter darker distally and with outer feathers pale blue shading to white at tips. Female similar but generally greener with head browner. Immature duller. Race *semitorquatus* larger, with strong red frontal band, green belly; *occidentalis* smaller, with pale blue lower ear-coverts and yellow of belly extending to undertail-coverts.

Habitat. Wide variety used, including dense coastal forests, wheatbelt farmlands, mallee and semi-arid *Eucalyptus* woodlands, arid *Acacia* or *Casuarina* interior scrublands and even sparsely vegetated country as long as tree-lined watercourses penetrate them to provide nest-sites.

Food and Feeding. In forest areas, fruits and sometimes nectar of *Eucalyptus*, especially marri (*E. calophylla*), and other species, including exotic ornamentals such as *Melia azedarach*; in

more arid country, seeds of grasses and herbaceous plants, with birds seen digging up corms of onion grass (*Romulea longifolia*), eating small leaves of capeweed (*Cryptotemma calandula*) and taking grain spilt by lorries along roads. Stomachs held seeds of *Lysiana exocarpi*, *Solanum* and mistletoe, *Eremophila* buds, and wood-boring larvae. Birds pull back eucalypt bark to obtain lerps, and eat sawfly *Perga* larvae from eucalypt seedlings and *Macrobathra* moth larvae from galls on *Cassia*; and can damage cereal crops and cultivated fruit.

Breeding. Aug-Feb in C and S of range, sometimes with two broods; Jun-Sept in N of range. Nest in hole in tree, commonly in salmon gum (*Eucalyptus salmonophloia*) and wandoo (*E. wandoo*). Eggs 4-7, usually 5; incubation lasts 19 days; nestling period c. 5 weeks.

Movements. Normally sedentary in more wooded parts of range, but in arid country nomadic movements recorded, e.g. many thousands appeared on NW edge of Nullarbor Plain, Jan 1975, and are probably common in response to water availability.

Status and Conservation. Not globally threatened, CITES II. A fairly common species throughout one-third of Australian continent, and abundant in Western Australian wheatbelt (considered perhaps the commonest bird species) where in two shires an open season has existed to control crop depredations; the creation of reservoirs for livestock has benefited populations in pasturelands. However, poor regeneration of nest-trees, which are many hundreds of years old, is a long-term cause for concern.

Bibliography. Baumgarten (1990), Blakers *et al.* (1984), Brooker (1973), Brooker *et al.* (1979), Cain (1955), Christidis & Boles (1994), Emison *et al.* (1987), Fisher (1970), Forshaw (1981b), Hall (1974), Jenkins (1969), Laubscher (1997b), Lindsey, T.R. (1992), Long (1984, 1985), Macdonald (1988), Mawson & Long (1994), Nichols (1978), Pizzey & Doyle (1980), Richardson & Wooller (1990), Robinson (1960), Saunders & Ingram (1995), Schodde & Tidemann (1986), Simpson & Day (1996), Stoneman *et al.* (1997), Storr (1977), Tronson & Tronson (1987), Vriends (1979).

81. Mallee Ringneck

Barnardius barnardi

French: Perruche de Barnard **German:** Barnardsittich **Spanish:** Perico de Barnard
Other common names: Barnard's Parakeet, Eastern Ringneck; Cloncurry Parrot (*macgillivrayi*)

Taxonomy. *Platycercus Barnardi* Vigors and Horsfield, 1827, New South Wales.

Genus sometimes combined into *Platycercus*. Forms a parapatric species pair with *B. zonarius*, with which often considered conspecific. Race *macgillivrayi* may be closer to *B. zonarius*, and may be separate species; race *whitei* apparently hybridizes sometimes with *B. zonarius*. Three subspecies recognized.

Subspecies and Distribution.

B. b. macgillivrayi (North, 1900) - E Northern Territory and NW Queensland.

B. b. whitei (Mathews, 1912) - Flinders Ranges, South Australia.

B. b. barnardi (Vigors & Horsfield, 1827) - SE Australia.

Descriptive notes. 33 cm; 105-143 g. Head and undersides mainly green, but with red frontal band, dark green hindcrown joined to postocular stripe, and pale blue tinge at base of bill; yellow half-collar across nape; mantle and back blackish blue; scapulars and secondaries dark green; lesser wing-coverts dark blue; primary and outermost secondary coverts pale blue; median and other secondary coverts green; primaries blackish; rump mid-green; tail dark green with blue outer feathers that shade to white at tips. Female duller, with paler mantle and evidence of wing stripe. Immature like female with brownish

green head. Race *whitei* has dark grey-green mantle, brownish crown; *macgillivrayi* lacks red forehead and replaces dark green of crown, mantle and tail with paler green, as well as having more blue on face, and belly yellow.

Habitat. Mallee (low *Eucalyptus* scrubland), open woodland and trees along watercourses. *Callitris* woodland and *Acacia* scrub; race *macgillivrayi* prefers woodland savanna and riverside forest, especially in hilly country.

Food and Feeding. Seeds of paddy melons (*Cucumis myriocarpus*), bitter melons (*Citrullus lanatus*), fruits of the introduced tobacco tree (*Nicotiana glauca*), and blossoms and seeds of various *Eucalyptus* species, including *E. camaldulensis*, *E. gracilis* and *E. cladocalyx*, are known to be favoured. Commonly feeds on ground, and grass seeds, plus those of Portulacaceae and *Solanum*, have been found in stomachs.

Breeding. Aug-Jan, if not delayed or even prevented by drought, but occasionally with two broods reared; Feb-Jun for *macgillivrayi*. Nest in hollow limb or hole in tree; *macgillivrayi* selects *Eucalyptus camaldulensis*. Eggs 4-6; incubation lasts c. 20 days; nestling period c. 5 weeks.

Movements. Generally sedentary, although local movements may occur in response to climatic conditions.

Status and Conservation. Not globally threatened, CITES II. Still common in many areas, but apparently intolerant of human settlement of range, declining in face of mallee and woodland clearance for grazing and cultivation. Race *macgillivrayi*, often judged uncommon, is fairly plentiful and widespread.

Bibliography. Blakers *et al.* (1984), Cain (1955), Christidis & Boles (1994), Emison *et al.* (1987), Fisher (1970), Ford (1988), Ford & Parker (1974), Forshaw (1981b), Hall (1974), Horton (1975), Lindsey, T.R. (1992), Macdonald (1988), Pizzey & Doyle (1980), Schodde & Tidemann (1986), Simpson (1973), Simpson & Day (1996), Storr (1973), Tronson & Tronson (1987), Vriends (1979).

Genus *PLATYCERCUS* Vigors, 1825

82. Green Rosella

Platycercus caledonicus

French: Perruche à ventre jaune **German:** Gelbbauchsittich **Spanish:** Perico de Tasmania
Other common names: Tasmanian Rosella

Taxonomy. *Psittacus caledonicus* J. F. Gmelin, 1788, New Caledonia; error = Adventure Bay, Tasmania.

Monotypic.

Distribution. Tasmania and larger Bass Strait islands.

Descriptive notes. 36 cm; 90-165 g. Bill whitish, broad frontal band red, lower cheek and chin grey-blue; rest of head yellow, mottled black on nape; upperparts and tail dull green, with lighter edges on mantle and scapulars creating vague scaled effect, and with pale grey-blue on wing coverts, outer edges of primaries, and outer tail feathers; underparts yellow sometimes washed orange, and with orange flecks around vent. Female smaller, usually with orange around throat. Immature mostly dull green.

Habitat. All wooded habitats within range are used, birds penetrating urban areas and visiting orchards and gardens, but chief habitat is sclerophyll forest and savanna woodland; on Hunter I. apparently prefers rock-strewn gullies.

Food and Feeding. Seeds of eucalypts, myrtle, sassafras, *Acacia dealbata*, *Senecio linearifolius*, *Rumex*, *Solanum*, *Pimelea* and other trees, shrubs and grasses; berries of *Coprosma* and *Cyathodes* shrubs at higher altitudes, and of hawthorn *Crataegus* in winter; leaf-buds of *Salix viminalis*. *Schedorhiza* psyllids and insect larvae also taken.

Breeding. Sept-Feb. Nest in hollow limb or hole in tree, usually a eucalypt, but also in walls of remote decayed buildings and in one (failed) case when no suitable hollows available the disused nest of a passerine. Eggs 4-6; incubation lasts 19 days; nestling period c. 5 weeks.

Movements. Sedentary; birds in higher areas presumably descend to lower-lying areas in winter, although presence in winter near summits has been recorded. There is evidence of former wandering by flocks of immatures.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Common throughout small range, and only on King I. where much *Eucalyptus* has been cleared, has there been a significant reduction in numbers.

Bibliography. Blakers *et al.* (1984), Brothers (1979), Brown, P.B. (1977, 1984), Cain (1955), Forshaw (1981b), Green (1969, 1977a, 1977b), Green & McGarvie (1971), Green & Swift (1965), Lea & Gray (1935), Lindsey, T.R. (1992), Macdonald (1988), McColl (1957), Mollison (1974), Oviden *et al.* (1987), Pizzey & Doyle (1980), Ridpath & Moreau (1966), Schodde & Tidemann (1986), Sharland (1956), Simpson & Day (1996), Tronson & Tronson (1987), Vriends (1979).

83. Crimson Rosella

Platycercus elegans

French: Perruche de Pennant **German:** Pennantsittich **Spanish:** Perico Elegante
Other common names: Pennant's Parakeet, Pennant's/Blue-Cheeked Rosella

Taxonomy. *Psittacus elegans* J. F. Gmelin, 1788, New South Wales.

Forms a superspecies with *P. flaveolus*, with which often regarded as conspecific, due to extensive hybridization zone; *P. adelaidae* too commonly considered conspecific, and may also belong in the superspecies. Three subspecies recognized.

Subspecies and Distribution.

P. e. nigrescens E. P. Ramsay, 1888 - NE Queensland.

P. e. elegans (J. F. Gmelin, 1788) - SE Queensland to SE South Australia.

P. e. melanoptera North, 1906 - Kangaroo I (South Australia).

Introduced (probably *elegans*) to Norfolk I and New Zealand.

Descriptive notes. 36 cm; 112-169 g. Plumage predominantly red; bill whitish; dark red frontal band through eye, with broad grey-blue lower cheek; feathers of mantle, back and scapulars black edged red, giving scaled effect; lesser wing-coverts black, median and outer secondary coverts and outer secondaries pale grey-blue, flight-feathers blackish; tail above deep blue, lateral feathers tipped white, below pale grey-blue. Female similar to male. Immature largely green, retaining red and blue on crown and face, with red on vent. Race *nigrescens* darker and smaller; *melanoptera* has more black on

back.

Habitat. Coastal and adjacent mountain forests and clearings from sea-level to alpine woodlands at 1900 m, also penetrating outer suburbs of cities; most numerous in wet forests and wet woodlands.

Food and Feeding. Seeds of native pines *Callitris endlicheri*, blue fig (*Elaeocarpus grandis*), eucalypts and acacias, plus those of smaller introduced and native plants such as *Rosa rubiginosa*, *Rumex acetosella*, *Helichrysum scorpioides*, *Crataegus*, *Cotoneaster*, *Pyracantha*, *Danthonia*, *Stellaria media*, *Trifolium dubium*, *Onopordon acanthium*. At one site in S of range the seeds, fruits or blossoms of *Leptospermum*, *Melaleuca*, *Banksia*, *Casuarina*, *Pomaderris*, *Leucopogon*, *Kunzea*, *Spyridium* and most small shrubs, grasses and seaboard succulents were used. Stomachs have been found to hold Hemiptera and psyllid, termite, aphid and beetle larvae. Birds are sometimes a pest in apple, pear, plum and quince orchards.

Breeding. Aug-Feb or later. Nest in hollow limb or trunk of tree, usually a live or dead eucalypt; one record of repeat nesting in girder of operating crane. Eggs 4-7, rarely 8; incubation lasts 19 days; nestling period c. 5 weeks.

Movements. Nomadic movements reported in winter at edges of range, but otherwise sedentary.

Status and Conservation. Not globally threatened. CITES II. Generally common to abundant, but has lost ground to land clearance, when it is replaced by *P. eximius*.

Bibliography. Blakers *et al.* (1984), Cain (1955), Carter (1996), Chambers (1989), Christidis & Boles (1994), Cooper, R.P. (1975), Emison *et al.* (1987), Ford (1977), Forshaw (1981b), Hamel (1970), Hermes (1985), Lenz (1988), Lever (1987), Lindsey, T.R. (1992), Macdonald (1988), Oviden *et al.* (1987), Pizzey & Doyle (1980), Robertson (1985), Rose (1997b), Schodde & Tidemann (1986), Schodde *et al.* (1983), Simpson & Day (1996), Storr (1973), Tronson & Tronson (1987), Turner *et al.* (1968), Vriends (1979), Wyndham & Cannon (1985).

84. Yellow Rosella

Platycercus flaveolus

French: Perruche flavéole

German: Strohsittich

Spanish: Perico Gualda

Taxonomy. *Platycercus flaveolus* Gould, 1837, New South Wales.

Forms a superspecies with *P. elegans*, with which often regarded as conspecific, due to extensive hybridization zone; *P. adelaidae* too commonly considered conspecific, and may also belong in the superspecies. Monotypic.

Distribution. Interior SE Australia centred on the Murray-Murrumbidgee river systems.

Descriptive notes. 33-34 cm; 105-135 g. Similar to *P. elegans* but with pale yellow replacing all red, except for orange-red frontal band and lores, and with some orange-red markings on breast. Female usually has more orange-red breast markings, and often a pale underwing stripe. Immature has reduced frontal band, upperparts dull olive-green, underparts tinged greenish yellow; has underwing stripe.

Habitat. Stands of riverine red gums (*Eucalyptus camaldulensis*), especially where they form savanna woodland on floodplains, ranging out into adjacent mallee and farmland to

feed. Where sympatric, *P. elegans* uses box-ironbark and peppermint forests, not penetrating red gums.

Food and Feeding. Seeds and blossoms of *E. camaldulensis* and unspecified shrubs and grasses, and in autumn seeds of *Polygonum hydropiper* and *Onopordon acanthium*; seeds of paddy melon (*Cucumis myriocarpus*) and larvae of the cup moth (*Limacodes longerans*) also recorded.

Breeding. Aug-Jan. Nest high in large eucalypt. Eggs 4-5; incubation lasts 19 days; nestling period c. 5 weeks.

Movements. Formerly nomadic at edges of range, but now absent from these areas.

Status and Conservation. Not globally threatened. CITES II. Fairly common within restricted range, but has suffered some losses owing to large-scale irrigation schemes.

Bibliography. Blakers *et al.* (1984), Christidis & Boles (1994), Cole (1919), Emison *et al.* (1987), Ford (1977), Forshaw (1981b), Lindsey, T.R. (1992), Macdonald (1988), Oviden *et al.* (1987), Pizzey & Doyle (1980), Schodde & Tidemann (1986), Schrader (1979), Simpson (1973), Simpson & Day (1996), Tronson & Tronson (1987), Vriends (1979).

85. Adelaide Rosella

Platycercus adelaidae

French: Perruche d'Adélaïde

German: Adelaidesittich

Spanish: Perico de Adelaida

Taxonomy. *Platycercus Adelaidae* Gould, 1841, South Australia.

Often treated as conspecific with *P. elegans* and *P. flaveolus*, and has commonly been considered to represent a hybrid form of these two; alternatively, these three may form a superspecies; further investigation required. Two subspecies recognized.

Subspecies and Distribution.

P. a. subadelaidae Mathews, 1912 - S South Australia in S Flinders Ranges.

P. a. adelaidae Gould, 1841 - S South Australia from Mt Lofty Ranges to Fleurieu Peninsula.

Descriptive notes. 36 cm; 100-165 g. Very similar to *P. elegans* but individually variable: generally orange-red with narrow yellow edges to feathers of underparts and rump, amount of yellow increasing on flanks and sides of neck, with edges of mantle and back feathers yellow, those on wing-coverts orange-yellow. Female similar. Immature duller with breast and belly greyish green, upperparts olive-green, with underwing stripe. Race *subadelaidae* has orange-yellow underparts but head, flanks and rump far yellower.

Habitat. All types of wooded country, frequently penetrating suburban gardens and parks and regularly visiting farmyards to pick up spilt grain. Race *subadelaidae*, like *P. flaveola*, is largely confined to riverine red gum (*Eucalyptus camaldulensis*).

Food and Feeding. Diet consists of seeds of *Eucalyptus*, especially *E. camaldulensis*; also takes *Solanum nigrum*, *Xanthorrhoea spatha*, *Trifolium glomeratum*, *Acacia*, *Carduus tenuiflorus*; grains of cultivated cereals. Insect remains also found in stomachs, and berries witnessed being taken.

Breeding. Sept-Dec. Nest in hollow in live or dead eucalypt. Eggs 4-5, rarely 7; incubation lasts 19 days; nestling period c. 30 days.

Movements. Sedentary, but with local irregular movements at edges of range.

Status and Conservation. Not globally threatened. CITES II. Nominant race abundant within very small range, but *subadelaidae* local and uncommon.

Bibliography. Blakers *et al.* (1984), Boehm (1959), Cain (1955), Christidis & Boles (1994), Fisher (1993), Forshaw (1981b), Lea & Gray (1935), Lindsey, T.R. (1992), Macdonald (1988), Oviden *et al.* (1987), Pizzey

& Doyle (1980), Schodde & Tidemann (1986), Simpson & Day (1996), Tronson & Tronson (1987), Vriends (1979).

86. Northern Rosella

Platycercus venustus

French: Perruche gracieuse

German: Brownsittich

Spanish: Perico Gracioso

Taxonomy. *Psittacus venustus* Kuhl, 1820, Arnhem Bay, Northern Territory.

Forms a superspecies with *P. adscitus* and *P. eximius*, and sometimes considered conspecific with both. Monotypic.

Distribution. N Australia and offshore islands from Barkly Tableland to King Sound.

Descriptive notes. 28 cm; mean 85 g. Bill whitish; head black except for off-white lower cheek and chin; underparts, lower back and rump pale yellow lightly edged black, giving weak scaled effect; vent red; nape, mantle and scapulars black with broad pale yellow edges, giving strong scaled effect; lesser wing-coverts black, median coverts blue-grey, remaining wing-coverts black edged yellow (inner) and blue-grey (outer), primaries black; tail bronze green centrally, outer feathers dark blue shading paler to white tips. Female similar. Immature duller and dusker, with scattered red in head, less red on vent.

Habitat. *Eucalyptus* and *Melaleuca* woodland in hilly country where access to water greater, plateau woodlands including those dominated by *Callitris intratropica*, occasionally visiting mangroves, parks and gardens.

Food and Feeding. Seeds of eucalypts, *Melaleuca* and *Acacia*, also *C. intratropica*; grass seeds and nectar also recorded. Birds in coastal woods sometimes feed on shoreline and creek banks.

Breeding. Jun-Sept, sometimes earlier. Nest in hollow limb or hole in tree, usually a eucalypt near water. Eggs 2-4; incubation lasts c. 19 days; nestling period c. 7 weeks.

Movements. Probably mainly sedentary, although in dry season birds retreat to vicinity of water-courses.

Status and Conservation. Not globally threatened. CITES II. Considered to be relatively uncommon overall, and only locally common. Evidence of former abundance disputed, so not clear if any decline has actually occurred since mid-19th century, and in any case no clear cause discernible; possibly this species has always been limited by habitat, especially the availability of dry-season refuges.

Bibliography. Blakers *et al.* (1984), Cain (1955), Christidis & Boles (1994), Forshaw (1981b), Johnstone *et al.* (1977), Lindsey, T.R. (1992), Macdonald (1988), Ovenden *et al.* (1987), Pizzey & Doyle (1980), Schodde & Tidemann (1986), Simpson & Day (1996), Smith *et al.* (1978), Storr (1977, 1980), Storr *et al.* (1975), Tronson & Tronson (1987), Vriends (1979).

87. Pale-headed Rosella

Platycercus adscitus

French: Perruche à tête pâle

German: Blaßkopfsroella

Spanish: Perico Pálido

Other common names: Mealy Rosella

Taxonomy. *Psittacus adscitus* Latham, 1790, Cooktown, Queensland.

Forms a superspecies with *P. venustus* and *P. eximius*, and sometimes considered conspecific with both. Two subspecies recognized.

Subspecies and Distribution.

P. a. adscitus (Latham, 1790) - N Queensland.

P. a. palliceps Lear, 1832 - Queensland and N New South Wales.

Descriptive notes. 30 cm; 100-175 g. Bill and face white shading to yellow, lightly edged black, on nape and sides of neck; chin and lower cheeks grey-blue; mantle, back and scapulars black with broad yellow edges, making scaled effect, rump yellow; wing as in *P. venustus*; breast pale yellow shading to pale blue on belly; vent and undertail-coverts red; tail bluish green centrally, outer feathers blue tipped white. Female similar to male, but has pale underwing stripe. Immature like female but duller. Race *palliceps* lacks blue-grey on cheeks but usually has entire underparts grey-blue; rump pale blue to greenish blue.

Habitat. Occurs in variety of habitats, including savanna woodland, paperbark woodland, riverine and swamp growth, *Banksia*-dominated coastal heath, wet sclerophyll forest, fringes of lowland rain forest, farmland and clearings.

Food and Feeding. Wide range of plants utilized, with 47 species recorded; forages more arboreally than *P. eximius*. Seeds of *Eucalyptus camaldulensis*, *Casuarina cunninghamiana*, *Melaleuca linariifolia*, *Onopordon acanthium*, *Xanthium chinense*, *X. spinosum*, *Callitris* and *Acacia* recorded, also blossoms of *Melaleuca*, fruits of *Dodonaea triquetra*. Can be a pest in orchards and maize fields.

Breeding. Feb-Jun in N, though with some variation depending on rainfall, Sept-Dec in S. Nest in deep hollow in living or dead tree, preferably a eucalypt near a watercourse, but also in stump or hollow fence post. Eggs 3-5; incubation lasts 19 days; nestling period c. 5 weeks.

Movements. Sedentary; some local movements at the edges of range are related to climatic pressures.

Status and Conservation. Not globally threatened. CITES II. Abundant throughout most of range, benefiting from agriculture and cereal cultivation; only in S, where sympatric with closely related *P. eximius*, is it patchy in numbers.

Bibliography. Blakers *et al.* (1984), Bravery (1970), Cain (1955), Cannon (1979b, 1981, 1983, 1984b, 1984d), Christidis & Boles (1994), Forshaw (1981b), Gill (1970), Lindsey, T.R. (1992), Macdonald (1988), Ovenden *et al.* (1987), Pizzey & Doyle (1980), Roberts & Ingram (1976), Schodde & Tidemann (1986), Simpson & Day (1996), Tronson & Tronson (1987), Vriends (1979), Wyndham & Cannon (1985).

88. Eastern Rosella

Platycercus eximius

French: Perruche omnicolore

German: Rosella

Spanish: Perico Multicolor

Other common names: Golden-mantled/White-cheeked Rosella

Taxonomy. *Psittacus eximius* Shaw, 1792, New South Wales.

Forms a superspecies with *P. venustus* and *P. adscitus*, and sometimes considered conspecific with both. Three subspecies recognized.

Subspecies and Distribution.

P. e. ceciliae Mathews, 1911 - SE Queensland and NE New South Wales.

P. e. eximius (Shaw, 1792) - SE New South Wales, Victoria and SE South Australia.

P. e. diemenensis North, 1911 - Tasmania.

Introduced to New Zealand (probably *eximius*).

Descriptive notes. 30 cm; 90-120 g. Bill whitish, with white lower cheeks and chin; rest of head and breast red, upper belly yellow, lower belly pale green, undertail-coverts red; mantle, back and scapulars black edged yellow, creating scaled effect; median wing-coverts black, lesser wing-coverts, outer secondary coverts and flight-feathers edged grey-blue; tail bottle green centrally, with outer feathers blue-grey tipped white. Female has duller red head and pale underwing stripe. Immature like female with green to back of head. Race *ceciliae* has darker red head, richer yellow on back, blue-green rump; *diemenensis* has larger cheek patches, darker red head.

Habitat. Lightly wooded landscapes including savanna woodland, mallee, open forest, riverine growth, farmland, gardens and parks, up to 1250 m; preference in Victoria for *Banksia* woodlands and *Eucalyptus camaldulensis* associations.

Food and Feeding. Wide range of plant species used, with 82 recorded in one study. Seeds of *Eucalyptus* and *Acacia* are particularly favoured, with seeds of many shrubs and grasses also taken, e.g. *Capsella bursapastoris*, *Cerastium vulgatum*, *Melilotus alba*, *Onopordon acanthium*, *Carduus marianus*, *Hypochaeris radicata*, *Actinotus helianthi*, *Amaranthus* and *Oxalis*: sometimes extracts seeds from dung. Other food recorded includes berries of *Pyracantha* and *Crataegus*, eucalypt blossoms, *Populus* leaf-buds, *Gazania* leaves, insects and their eggs and larvae, *Schedorhiza* psyllids (animal material notably in Jul); commonly takes spilt grain in farmyards and at roadsides, and can be a pest in orchards.

Breeding. Aug-Feb, occasionally Apr-May. Nest in hollow limb or hole in tree, generally a eucalypt, or in stump, fence post, fallen log, rabbit burrow, enlarged tunnel of Rainbow Bee-eater (*Merops ornatus*), disused hole of Laughing Kookaburra (*Dacelo novaeguineae*) in an arboreal termitarium, elkhorn fern on side of house, rock face, buildings and even a deserted nest of a babbler (*Pomatostomus*). Eggs 4-9, usually 5; incubation lasts 19 days; nestling period c. 35 days.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Extremely common in most of range, but only locally numerous in Tasmania. Has benefited from clearance of forested areas for pasture and cereal cultivation.

Bibliography. Baldwin (1976), Blakers *et al.* (1984), Brereton & Pidgeon (1966), Cain (1955), Cannon (1979b, 1981, 1983, 1984b, 1984d), Carter (1996), Chambers (1989), Christidis & Boles (1994), Cooper, R.P. (1975), Emison & Porter (1978), Emison, Beardsell *et al.* (1987), Emison, Norris & Apps (1978), Forshaw (1981b), Green & Swift (1965), Hamel (1970), Kloot & McCulloch (1993), Lane (1994), Lea & Gray (1935), Lever (1987), Lindsey, T.R. (1992), Macdonald (1988), Ovenden *et al.* (1987), Parker (1988), Pfeffer (1997b), Pizzey & Doyle (1980), Rakos (1992b), Robertson (1985), Rose (1997b), Rostron (1969), Satterthwaite (1993), Schodde & Tidemann (1986), Simpson & Day (1996), Tronson & Tronson (1987), Tzaros (1992, 1993), Vriends (1979), Wyndham & Brereton (1982), Wyndham & Cannon (1985), Wyndham *et al.* (1983).

89. Western Rosella

Platycercus icterotis

French: Perruche à oreilles jaunes

German: Gelbwangenrosella

Spanish: Perico Carigualdo

Other common names: Stanley Parakeet

Taxonomy. *Psittacus icterotis* Kuhl, 1820, Albany, south-western Australia.

Two subspecies recognized.

Subspecies and Distribution.

P. i. xanthogenus Salvadori, 1891 - interior SW Australia.

P. i. icterotis (Kuhl, 1820) - coastal SW Australia.

Descriptive notes. 25-26 cm; 52-80 g. Bill whitish; head and underparts red except for ear-coverts and face below eye yellow, and some green barring on flanks; nape, mantle and scapulars black with red edges, becoming pale green edges with red tips lower down, giving a scaled effect; inner wing-coverts dull green, outer dark blue, black on median coverts; primaries blackish; rump and tail dark green with outer feathers blue tipped white. Female has largely green head with red on forehead, smaller, duller yellow facial patch, much green in breast and no red in mantle; pale underwing stripe. Immature like female with no yellow in

face and little red in underparts. Race *xanthogenus* has paler yellow face, buff not green in back scaling, rump dull green to greyish olive and tail dull blue.

Habitat. Open forest, tree-lined cereal fields, riverine growth such as jarrah (*Eucalyptus marginata*), *Banksia* and tea-tree thickets, *Acacia*-*Casuarina* scrublands, grasslands and orchards.

Food and Feeding. Seeds of grasses and herbs, with birds visiting stubblefields to pick up grain; fruits, berries, flowers of *E. marginata*, coating of zamia palm (*Macrozamia reidii*) seeds and ripening apples also recorded, and some damage may be done in orchards.

Breeding. Aug-Dec. Nest in hollow limb or hole in tree, commonly in salmon gum (*E. salmonophloia*) and wandoo (*E. wandoo*). Eggs 3-7, usually 5; incubation lasts 19 days; nestling period c. 5 weeks.

Movements. Generally sedentary, but in Moora district birds arrive in Dec to breed and depart in Jun-Jul.

Status and Conservation. Not globally threatened. CITES II. Relatively common and has benefited from clearance of closed forest. However, numbers may be naturally depressed by *Barnardius zonarius*, a larger competitor for the same food resources. Moreover, poor regeneration of nest-trees is a long-term cause for concern, and there have been local declines and losses. The species is protected by law, but in two shires an open season has existed to control crop depredations.

Bibliography. Blakers *et al.* (1984), Cain (1955), Forshaw (1981b), Garstone (1974), Hall (1974), Lindsey, T.R. (1992), Loaring (1952), Long (1984, 1985), Macdonald (1988), Masters & Milhinch (1974), Mawson & Long (1994), Orton & Sandland (1913), Ovenden *et al.* (1987), Pizzey & Doyle (1980), Richardson & Wooller (1990), Saunders & Ingram (1995), Schodde & Tidemann (1986), Serventy & Whittell (1976), Simpson & Day (1996), Stoneman *et al.* (1997), Trounson & Trounson (1987), Vriends (1979).

wing stripe. Immature like female with smaller red belly patch. Race *haematorrhous* has greenish turquoise bend of wing, rufous-red wing-coverts, red from belly to vent; *pallascens* like nominate but paler below; *narethae* has blue forehead, buff flecks on breast, olive upperparts, belly yellow with red undertail-coverts, red outer lesser wing-coverts.

Habitat. Arid and semi-arid open woodlands dominated by *Myoporum*, *Casuarina*, *Callitris*, *Acacia* and *Eucalyptus*, often with low chenopod shrub layer; also open grassy plains, arid scrub, trees bordering water-courses, sometimes near farm buildings, water troughs. Remnant patches of mallee in cleared agricultural land are important in S of range.

Food and Feeding. Seeds of herbs, including *Atriplex vesicarium*, *Kochia sedifolia*, *Bassia* and *Amaranthus*, fruit, berries and acacia blossoms; relatively little grass seed. Race *narethae* recorded taking seeds of various *Acacia*, also *Heterodendron oleifolium*, *Danthonia caespitosa*, *Helipterum*, *Sonchus oleraceus* and the mistletoes *Amyema quandong* and *Lyiana exocarpi*, and lepidoptera larvae extracted from acacia trunks; reported also to prefer seeds of composites, mainly *Helipterum*, when feeding young.

Breeding. Jul-Dec, with some variation depending on rains, and evidence of two seasons following good rainfall. Nest in hollow in tree; *narethae* often uses very stunted trees, finding the nest-site at ground level in a fissure in the tree base, with western myall (*Acacia papyrocarpa*) a favoured species. Eggs 4-7; incubation lasts 19 days; nestling period c. 30 days.

Movements. Seasonal fluctuations in numbers of the race *narethae* appear to occur, suggesting local movements in response to food availability, but otherwise no evidence of movements.

Status and Conservation. Not globally threatened. CITES II. Fairly common except at edges of range. Clearance of native vegetation in Victoria needs to be halted to preserve shelter and nest-sites, but spread of European Starling (*Sturnus vulgaris*) into these habitats may result in parrots being excluded from nest-holes anyway. Race *narethae* suffers from illegal trapping, involving the cutting-out of nest cavities, which destroys the future potential of the site and therefore reduces the species's overall reproductive capacity; moreover, rabbit grazing may have been preventing regeneration of favoured nest tree species.

Bibliography. Antram (1991), Blakers *et al.* (1984), Boehm (1952), Brooker *et al.* (1979), Cain (1955), Calaby (1958), Emison (1992), Emison *et al.* (1987), Ford (1969), Forshaw (1981a, 1981b), Garnett (1993), Hall (1974), Henderson (1972), Joseph (1985), Lindsey, T.R. (1992), Macdonald (1988), Odekerken (1991), Pizzey & Doyle (1980), Schodde & Tidemann (1986), Simpson & Day (1996), Slater (1978), Storr (1973, 1986), Trounson & Trounson (1987), Vriends (1979), Walton (1993).

Genus *NORTHIELLA* Mathews, 1912

90. Bluebonnet

Northiella haematogaster

French: Perruche à bonnet bleu **German:** Blutbauchsittich **Spanish:** Perico Cariazul

Taxonomy. *Platycercus haematogaster* Gould, 1838, New South Wales.

Sometimes included in *Psephotus* or *Platycercus*. Race *narethae* may be incipient species. Four subspecies recognized.

Subspecies and Distribution.

N. h. haematorrhous (Gould, 1865) - S Queensland and N New South Wales.

N. h. haematogaster (Gould, 1838) - W & S New South Wales and NW Victoria to SE South Australia.

N. h. pallascens (Salvadori, 1891) - inland South Australia.

N. h. narethae (H. L. White, 1921) - SE Western Australia to SW South Australia.

Descriptive notes. 28 cm; 74-105 g. Forehead, lores and face purplish blue; head, breast, mantle, back and rump ochre shading to yellow on belly which has large central red blotch; bend of wing blue with most wing-coverts olive, outermost purplish blue; underwing-coverts and outer webs of flight-feathers purplish blue; tail greenish bronze with outer feathers purplish blue tipped white. Female possesses

ssp haematonotus

ssp caeruleus

PLATE 37

inches 5
cm 13

Genus *PSEPHOTUS* Gould, 1845

91. Red-rumped Parrot

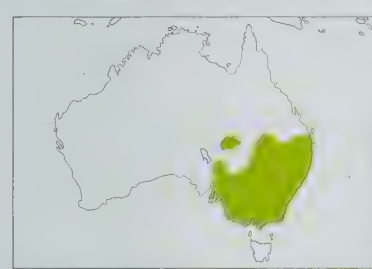

Psephotus haematonotus

French: Perruche à croupion rouge **German:** Singsittich **Spanish:** Perico Dorsirrojo

Taxonomy. *Platycercus haematonotus* Gould, 1838, New South Wales. Sometimes placed in genus *Platycercus*. Two subspecies recognized.

Subspecies and Distribution.

P. h. caeruleus Condon, 1941 - L Eyre region of South Australia and adjacent extreme SW Queensland.
P. h. haematonotus (Gould, 1838) - SE Australia.

Descriptive notes. 27 cm; 54-70 g. Head and breast grass green, with blue tinge on forehead and lower cheeks; belly yellow shading to white on undertail-coverts; mantle, back and scapulars glaucous green, median wing-coverts edged pale yellow, remaining wing-coverts edged pale blue-grey, primaries blackish edged blue; rump red, uppertail-coverts green, tail dark green tipped blackish, outer feathers tipped and edged whitish. Female dull brownish green above, yellowish olive below. Immature similar to female but duller. Race *caeruleus* paler and bluer.

Habitat. Open woodland, mallee, savanna grassland, riverine growth, notably with *Eucalyptus camaldulensis*, and in one locality mangroves; also farmland and urban areas; apparently up to around 1100 m.

Food and Feeding. Seeds and green tissues of grasses and herbaceous plants, e.g. *Erodium botrys*, *Foeniculum*, *Boerhavia*, *Kochia*, *Linum*, *Echinochloa crusgalli*, *Onopordon acanthium*, *Synara cardunculus*, *Echium plantagineum*, *Papaver hybridum* and *Stellaria media*, occasionally in eucalypts on seeds and flowers; also seen feeding on seed-capsules of *Goodenia ovata*, fallen seeds of *Schinus areira*, fruits of *Nitraria*.

Breeding. Aug-Jan, once Apr. Nest in hollow limb or hole in tree, usually a eucalypt near water, but also stumps, fence posts and in farm and suburban buildings, sometimes colonially. Eggs 4-8, usually 5; incubation lasts 19 days; nestling period c. 4 weeks.

Movements. Sedentary, except at edges of range, where local movements occur.

Status and Conservation. Not globally threatened. CITES II. Common to abundant throughout its range. Although at the start of the twentieth century it was reportedly declining owing to overgrazing and a disease outbreak, after mid-century it was found to have expanded its range E and W, apparently in response to forest clearance and cereal cultivation.

Bibliography. Blakers *et al.* (1984), Braby & Runtz (1988), Emison *et al.* (1987), Fleming (1974), Forshaw (1981b), Hall (1974), Klotz (1988), Lea & Gray (1935), Lindsey, T.R. (1992), Macdonald (1988), McLaughlin (1989), Morris (1975), Nielsen (1969), Pizzey & Doyle (1980), Rakos (1992a), Rose (1997b), Schodde & Tidemann (1986), Simpson (1973), Simpson & Day (1996), Tronson & Tronson (1987), Unfried (1997), Vaughan (1980), Vriends (1979), Westcott & Cockburn (1988).

92. Mulga Parrot

Psephotus varius

French: Perruche multicolore **German:** Vielfarbensittich **Spanish:** Perico Variado
Other common names: Many-coloured Parrot

Taxonomy. *Psephotus varius* Clark, 1910, apparently the head of Spencer Gulf, South Australia. Sometimes placed in genus *Platycercus*. Monotypic.

Distribution. SC Australia from extreme W to interior SE.

Descriptive notes. 27-28 cm; 53-70 g. Predominantly bright green, but with yellow frontal band, red hinderown, yellow lesser wing-coverts, dark blue on outer wing-coverts, blackish primaries, belly to undertail-coverts yellow with orange markings, yellowish green band and red patch on rump and uppertail-coverts respectively, tail dark blue washed green, outer feathers blue tipped white. Female much drabber olive-green, becoming paler on belly, with red lesser wing-coverts; pale underwing stripe. Immature like female but duller.

Habitat. Lightly wooded grasslands, mallee, arid scrublands, with range largely coincident

with that of mulga *Acacia aneura*, albeit in no strict association; often in vicinity of waterholes and seasonal creeks.

Food and Feeding. Seeds of grasses, herbs, trees and shrubs, including mulga and *A. tetragonophylla*, mistletoe *Amyma murrai*, the saltbushes *Atriplex vesicaria* and *Enchylaena tomentosa*, chickweed *Cerastium glomeratum*, *Chenopodium*, *Kochia*, *Bassia*, *Erodium* and *Lysiana exocarpi*; small grubs once recorded.

Breeding. Jul-Dec, but nesting extends virtually throughout year if conditions favourable. Nest in hollow limb or hole in tree, high up when tall trees available, but frequently in small, stunted trees, once in a sandbank and once in metal pipes used as posts. Eggs 4-7, usually 5; incubation lasts 19 days; nestling period c. 4 weeks.

Movements. No large-scale seasonal movements occur, with some pairs visiting nest-sites throughout the year. However, some nomadism may occur, if unexplained declines in certain areas prove to reflect natural displacements rather than man-caused disappearances.

Status and Conservation. Not globally threatened. CITES II. Locally common; uncommon in SW Australia. Although some decline in numbers may have occurred since European settlement, there is no evidence of a contraction of range.

Bibliography. Anon. (1997b), Blakers *et al.* (1984), Brooker & Estbergs (1976), Brooker *et al.* (1979), Emison *et al.* (1987), Forshaw (1981b), Hall (1974), Lea & Gray (1935), Lindsey, T.R. (1992), Macdonald (1988), Mack (1970), Moriarty (1972), Pizzey & Doyle (1980), Reid *et al.* (1973), Saunders & Ingram (1995), Schmidt (1978), Schodde & Tidemann (1986), Sedgwick (1952), Simpson & Day (1996), Smith, D. (1993), Smith, J. (1992), Storr (1973, 1977), Tronson & Tronson (1987), Vriends (1979), Würth (1997b).

93. Hooded Parrot

Psephotus dissimilis

French: Perruche à capuchon noir **German:** Colletsittich **Spanish:** Perico Capirotado

Taxonomy. *Psephotus dissimilis* Collett, 1898, Mary River, Northern Territory.

Sometimes placed in genus *Platycercus*. Forms a superspecies with *P. chrysopterygius* and *P. pulcherrimus*; close to former, and in past considered conspecific. Monotypic.

Distribution. NE Northern Territory, Australia.

Descriptive notes. 26 cm; 50-60 g. Similar to *P. chrysopterygius* but with all-black crown from base of upper mandible, darker brown uppersides, larger and brighter yellow wing-patch, red on underparts confined to vent. Female like female *P. chrysopterygius* but more shot with grey, and with emerald green not turquoise blue rump. Immature like female, male somewhat brighter.

Habitat. Open woodlands and savanna grasslands with an abundance of terrestrial termitaria, most nests being placed in ridge country, though some in low *Melaleuca*-dominated floodplains.

Food and Feeding. In early wet season seeds of perennial grasses (23 species of Poaceae) when available, otherwise seeds of herbaceous plants and annual grasses.

Breeding. Jan-Apr or May. Nest mainly in turreted termitaria. Eggs laid at 1-5-2-5 day intervals; average clutch size 4-3, with 50% of eggs laid producing fledglings.

Movements. Birds were formerly recorded as wet season immigrants (Nov-Mar) to Melville I, but unclear if they bred there or not.

Status and Conservation. Not globally threatened. CITES I. Currently considered near-threatened. A BirdLife "restricted-range" species. Decline of species since turn of century correlated with penetration of habitat by cattle, which destroy some nest-sites by rubbing against termitaria, and must also graze out part of the local food supply. However, still generally numerous, and population in one reserve estimated at 12,000 birds. Nest densities range from 0-45 to 0-70/km².

Bibliography. Barnicoat (1996), Blakers *et al.* (1984), Brouwer & Garnett (1990), Carr (1987), Collar & Andrew (1988), Fitzherbert & Baker-Gabb (1988), Forshaw (1981a, 1981b), Garnett (1993), Garnett & Crowley (1995a), Goodfellow (1935), Hutchins (1985), King (1978/79), Lindsey, T.R. (1992), Low (1994b), Macdonald (1988), McAllan (1992), Pizzey & Doyle (1980), Rakos (1991), Reed & Tidemann (1994), Schodde & Tidemann (1986), Simpson & Day (1996), Slater (1978), Tronson & Tronson (1987), Vriends (1979), Wheeler (1975).

94. Golden-shouldered Parrot

Psephotus chrysopterygius

French: Perruche à ailes d'or **German:** Goldschultersittich **Spanish:** Perico Aligualdo

Taxonomy. *Psephotus chrysopterygius* Gould, 1858, Australia at lat. 18° S, long. 141°30' E.

Sometimes placed in genus *Platycercus*. Forms a superspecies with *P. dissimilis* and *P. pulcherrimus*; close to former, and in past considered conspecific. Monotypic.

Distribution. S parts of Cape York Peninsula in Queensland, Australia.

Descriptive notes. 26 cm; 54-56 g. Forehead pale yellow, mid-crown from above eye black narrowing back to thin stripe down nape to mantle; rest of head and underparts turquoise blue but with green wash on face and broad red patch from belly to undertail-coverts; mantle, back and wing-coverts mid-brown but with median coverts golden yellow, other outer coverts edged blue and primaries blackish edged blue; rump turquoise blue, tail above dark greenish tinged blue, outer feathers tipped white, below pale blue tipped black. Female pale green with pale brownish crown and pale blue on face and lower ventral region; pale

underwing stripe. Immature like female, male somewhat brighter.

Habitat. Open forest dominated by *Eucalyptus* and *Melaleuca* in vicinity of extensive flats with terrestrial termitaria, with preference in breeding season for woodlands adjacent to watercourses, birds subsequently penetrating coastal and estuarine mangroves.

Food and Feeding. Small grass seeds, mainly firegrass (*Schizachyrium*) in the dry season, supplemented by legumes, both native desmodiums and introduced verano (*Stylosanthes hamata*), which are important sources of protein for nestlings; throughout the wet season herbs, sedges, notably *Scleria*, and other grasses, notably *Panicloa nervillema* and *Allotroopsis semialata*, are important.

On following pages: 95. Paradise Parrot (*Psephotus pulcherrimus*); 96. Bourke's Parrot (*Neopsephotus bourkii*); 97. Blue-winged Parrot (*Neophema chrysostoma*); 98. Elegant Parrot (*Neophema elegans*); 99. Rock Parrot (*Neophema petrophila*); 100. Orange-bellied Parrot (*Neophema chrysogaster*); 101. Turquoise Parrot (*Neophema pulchella*); 102. Scarlet-chested Parrot (*Neophema splendida*); 103. Swift Parrot (*Lathamus discolor*); 104. Budgerigar (*Melopsittacus undulatus*); 105. Ground Parrot (*Pezoporos wallicus*); 106. Night Parrot (*Geopsittacus occidentalis*).

Breeding. Apr-Jun, but second broods sometimes in Jul-Aug. Uses two types of termitaria: merid-ian mounds of *Antitermes laurensis* and conical mounds of *A. scopolus*, the latter being preferred for their greater termoregulation. Eggs 3-6; incubation lasts c. 20 days; nestling period c. 5 weeks.

Movements. Pronounced post-breeding dispersal, with some evidence suggesting this is into coastal areas including mangroves, but probably mostly only local. Little immigration seems to occur into former areas.

Status and Conservation. ENDANGERED. CITES I. A BirdLife "restricted-range" species. Sig-nificant decline and contraction of range since turn of century, the species now occupying a 120 x 225 km strip in centre of original range, and total population at start of breeding season is provi-sionally estimated to be around 2300 birds (including 100 bachelors), rising to around 3500-5000 birds at the end of the breeding period; c. 1500 held in captivity in Australia. Although commonly considered a victim of excessive trapping, the species loses food resources to grazing and dry-season burning of grasslands, and suffers predation by feral cats and disturbance by tourists. Period at start of rains apparently critical, as flush of new grass renders seeds hard of access; fires at this period open up patches of ground again, and the problem may be that there have been too few fires at the right time, owing to excessive man-caused dry-season burning. Invasion of open grassland areas by ti-trees (*Melaleuca viridiflora*), which is reducing appropriate habitat for the parrots by about 5% per decade, is also a consequence of the altered fire regime.

Bibliography. Blakers *et al.* (1984), Brouwer & Garnett (1990), Cain (1955), Carr (1987), Collar & Andrew (1988), Collar *et al.* (1994), Dunn (1992), Fitzherbert & Baker-Gabb (1988), Forshaw (1981a, 1981b), Garnett (1993), Garnett & Crowley (1994b, 1995b, 1997), Hutchins (1985), King (1978/79), Lindsey, T.R. (1992), Low (1994b), Macdonald (1988), Pizzey & Doyle (1980), Schodde & Tidemann (1986), Silva (1994b), Simpson & Day (1996), Slater (1978), Thomson (1935), Trounson & Trounson (1987), Vriends (1979), Weaver (1982, 1987), Wheeler (1975).

95. Paradise Parrot

Psephotus pulcherrimus

French: Perruche de paradis

German: Paradiessittich

Spanish: Perico del Paraíso

Taxonomy. *Platycercus pulcherrimus* Gould, 1845, Darling Downs, Queensland, Australia. Sometimes placed in genus *Platycercus*. Forms a superspecies with *P. dissimilis* and *P. chrysoterygius*. Monotypic.

Distribution. C & S and possibly N Queensland and N New South Wales (almost certainly ex-tinct).

Descriptive notes. 27 cm. Frontal band red, area round eye yellow, crown to nape black, rest of head and breast turquoise blue with greener tinging on cheeks and central breast; belly to undertail-coverts red; mantle, back and wings mid-brown, darker on primaries, and with median wing-coverts red; rump and uppertail-coverts turquoise blue; tail bronze tinged blue, outer feathers edged bluish white. Female has head and breast buff with pale or-ange edging, dark mid-crown, pale blue un-derparts, reduced red in wing; pale underwing stripe. Immature like female, male with some green on head.

Habitat. Open forest and savanna woodlands with grass ground-cover, especially in broad riverine valleys.

Food and Feeding. Seeds of native grasses, taken on ground.

Breeding. Recorded in Sept, Dec and Mar. Nest a chamber excavated in a terrestrial termitarium, or occasionally in a sandy riverbank. Eggs 3-5.

Movements. No information; presumably sedentary.

Status and Conservation. Almost certainly EXTINCT. CITES I. Demise attributed to burning seeding grass to provide green growth for cattle, combined with the effects of drought, overgrazing, the spread of prickly pears, and possibly also disease, trapping and egg-collecting. Last certainly recorded in 1927.

Bibliography. Blakers *et al.* (1984), Brouwer & Garnett (1990), Carr (1987), Chisholm (1922, 1929), Collar & Andrew (1988), Collar *et al.* (1994), Fisher (1986), Fitzherbert & Baker-Gabb (1988), Forshaw (1981a, 1981b), Fuller (1987), Fullick (1994b), Garnett (1993), Greenway, J.C. (1967), Joseph (1988b), King (1978/79), Lindsey, T.R. (1992), Low (1994b), Macdonald (1988), Pizzey & Doyle (1980), Schmidt (1986), Schodde & Tidemann (1986), Simpson & Day (1996), Slater (1978), Storr (1973), Trounson & Trounson (1987), Vriends (1979).

Genus NEOPSEPHOTUS Mathews, 1912

96. Bourke's Parrot

Neopsephotus bourkii

French: Perruche de Bourke

German: Bourkesittich

Spanish: Periquito Rosado

Taxonomy. *Euphema Bourkii* Gould, 1841, Bogan River, New South Wales. Often merged into genus *Neophema*, but recent biochemical data provide additional support for retaining this monotypic genus. Monotypic.

Distribution. W. CS & CE Australia.

Descriptive notes. 19 cm; mean 39 g. Brown with dark edgings on crown, nape and cheeks; slight blue tinging on forehead; area around eyes and base of bill whitish, shading pink on chin; breast brown broadly edged pink, belly rose-pink; flanks, thighs, vent, undertail-coverts and sides of rump pale blue; wing-coverts dark brown edged buff, primaries slate-brown with dull blue outer webs; tail above rust brown, darker distally, with outer feathers pale blue and edged whitish; below whitish. Female has little blue on forehead or pink on belly; has wing stripe.

Habitat. Dry *Acacia* scrubland, especially where mulga (*A. aneura*) is dominant.

Food and Feeding. Seeds of grasses, especially wind grass, and of herbs, taken on ground and in bushes. Also grass shoots, and seeds of *Acacia*, *Bassia* and *Cassia*.

Breeding. Generally Aug-Dec, but variable with rainfall. Nest in hollow in tree, 1-3 m up. Eggs 3-6; incubation lasts 18 days; nestling period c. 4 weeks.

Movements. Nomadic, often remaining in an area for many years and then disappearing.

Status and Conservation. Not globally threat-ened. CITES II. Fairly common and apparently increasing, probably owing to the increase in stock-watering installations, although also perhaps attributable to reduction in sheep num-bers or a change in ground vegetation from saltbush to herbs. A decline in the Murray--Darling and Lake Eyre regions before the

1920's was blamed on the introduction of cats, rabbits and sheep.

Bibliography. Badman (1981), Blakers *et al.* (1984), Cain (1955), Christidis & Boles (1994), Davies (1977), Eckert (1975), Ford (1961), Forshaw (1981b), Greenway, J.C. (1967), Hall (1974), Kennedy (1993), Lindgren (1973), Lindsey, T.R. (1992), Macdonald (1988), Parker (1969), Pizzey & Doyle (1980), Richardson & Wooller (1990), Rothstein (1992), Schodde & Tidemann (1986), Simpson & Day (1996), Storr (1977), Trounson & Trounson (1987), Vriends (1979), Zomer (1987).

Genus NEOPHEMA Salvadori, 1891

97. Blue-winged Parrot

Neophema chrysostoma

French: Perruche à bouche d'or

German: Feinsittich

Spanish: Periquito Crisóstomo

Other common names: Blue-winged Grass-parakeet

Taxonomy. *Psittacus chrysostomus* Kuhl, 1820, New Holland; error = Tasmania. Monotypic.

Distribution. SE Australia and Tasmania.

Descriptive notes. 20-21 cm; 44-61 g. Area between eye and bill, and postocular mark, yellow; dark blue line across forehead to front of eye, edged above pale blue; crown bronze shading to olive green on hindcrown and rest of head and upperparts; breast pale grey-green shading to yellow on rest of underparts and undersides of tail except orange tinge to central belly; wing-coverts and flight-feathers dark blue; tail bluish grey, outer feathers tipped yellow. Female has olive green crown and smaller line on forehead, underparts tinged dull green. Immature dull, lacks line on forehead.

Habitat. Eucalypt woodland in breeding season, visiting pastures, clearings and orchards; similar habitat in winter, but also *Acacia* scrubland, lightly wooded grassland, arid saltbush *Atriplex* plains, coastal and mountain heaths, lignum swamps and coastal dunes and saltmarshes.

Food and Feeding. Seeds of grasses, notably *Danthonia semibarbata*, *D. semiannularis*, *Aira caryophylla* and *Drosera peltata*, also *Poa caespitosa*; seeds of herbs including *Cryptostemma calendulaceum*, *Stenopetalum lineare*, *Helipterum jessenii*, *H. pygmaeum* and *Astroloma humifusum*. Birds have been seen digging up newly sown seeds, and invertebrates may also be taken.

Breeding. Oct-Jan. Nest in hole in tree, often a high eucalypt, but also in a stump, fence post or fallen log; sometimes colonial. Eggs 4-6; incubation lasts 18-20 days; nestling period c. 30 days.

Movements. Migratory, although pattern unclear. Most birds in Tasmania move to mainland in winter, and N parts of range only visited at that time; it is suspected that the same birds are in-volved, leap-frogging resident populations in SE Australia and apparently using a geographical loop.

Status and Conservation. Not globally threatened. CITES II. Common, especially in Tasmania, SW Victoria and SE South Australia.

Bibliography. Blakers *et al.* (1984), Cain (1955), Cox (1974), Emison, Beardsell *et al.* (1987), Emison, Norris & Apps (1978), Forshaw (1981b), Green (1969, 1977a, 1977b), Green & McGarvie (1971), Greenway, J.C. (1967), Hall (1974), Lea & Gray (1935), Lindsey, T.R. (1992), Macdonald (1988), McColl (1957), Morris (1989, 1990), Norris *et al.* (1979), Pizzey & Doyle (1980), Schodde & Tidemann (1986), Simpson & Day (1996), Trounson & Trounson (1987), Vriends (1979), Zomer (1987).

98. Elegant Parrot

Neophema elegans

French: Perruche élégante

German: Schmucksittich

Spanish: Periquito Elegante

Other common names: Elegant Grass-parakeet

Taxonomy. *Nanodes elegans* Gould, 1837, Tasmania?; error = Victoria. Monotypic.

Distribution. SW & SE Australia, including Kangaroo I.

Descriptive notes. 22-23 cm; 42-51 g. Extremely similar to *N. chrysostoma* but plumage brighter and more yellowish notably on breast, with inner wing-coverts concolorous with mantle, reducing amount of blue in wing, and with outer median coverts pale blue; pale blue upper fringe to line across forehead more prominent and replaces yellow postocular patch; no bronze in crown. Female duller olive-green. Immature like female with reduced line on forehead.

Habitat. Coastal dunes, wooded and shrubby grasslands, mallee, eucalypt woodland, dry *Acacia* scrublands, bluebush flats and saltbush *Atriplex* plains, favouring clumps of trees within cleared areas.

Food and Feeding. Seeds of clover *Trifolium*, *Paspalum* grasses, *Lomandra* and several species of twinleaf *Zygophyllum* recorded.

Breeding. Aug-Nov. Nest in hollow usually high in tree, often in horizontal hollows in high limbs of isolated trees or trees in isolated clumps. Eggs 4-5; incubation c. 18 days; nestling period c. 30 days.

Movements. Partly nomadic, particularly at the edges of range; some small-scale seasonal movements may also occur, but records too few to determine pattern. Records from Kangaroo I are from Nov-Apr, suggesting breeding presence followed by winter period on mainland.

Status and Conservation. Not globally threatened. CITES II. Common, particularly in SW Australia, where since 1930's numbers and

range have increased in apparent response to land clearance and the use of clover *T. subterraneum* in pastures.

Bibliography. Baxter & Parker (1981), Blakers *et al.* (1984), Boehm (1959), Brooker & Estbergs (1976), Cain (1955), Chapple & Lewis (1991), Cox (1973), Forshaw (1981b), Garstone (1974), Greenway, J.C. (1967), Hall (1974), Lea & Gray (1935), Lindsey, T.R. (1992), Macdonald (1988), Masters & Milhinch (1974), Pizzey & Doyle (1980), Saunders & Ingram (1995), Schodde & Tidemann (1986), Serventy & Whittell (1976), Simpson & Day (1996), Trounson & Trounson (1987), Vriends (1979), Zomer (1987).

99. Rock Parrot

Neophema petrophila

French: Perruche des rochers German: Klippensittich Spanish: Periquito Roquero

Taxonomy. *Euphema petrophila* Gould, 1841, Western Australia. Monotypic.

Distribution. Coasts and islands of W & S Australia.

Descriptive notes. 22 cm; 47-54 g. Frontal band to eye dark blue vaguely edged pale blue including around eye and on lores; rest of head and upperparts brownish olive, washed greyer on breast and shading to yellow on rest of underparts; outermost median and secondary wing-coverts fringed pale blue; primary coverts and outer webs of flight-feathers dark blue; tail dark bluish olive, laterally edged yellow. Female duller. Immature lacks frontal band, whitish around eye.

Habitat. Coastal dunes, mangroves, saltflats, *Atriplex* shrublands, *Casuarina* woodland, brackish margins and rocky shorelines and

islets.

Food and Feeding. Seeds and fruits of grasses, shrubs and halophytic plants, notably *Carpobrotus aequilatus* and *C. crystallinus*, also *Lepidium foliosum*, *Correa reflexa*, *Atriplex*, *Rhagodia*, *Arthrocnemum arbuscula* and the introduced *Arctotheca nivea*; have been known to enter yards to take spilt wheat.

Breeding. Aug-Dec, rarely Feb; sometimes double-brooded. Nest in crevice in low cliff, rockface or overhang, recently all from islets, mostly limestone, where entrances often hidden behind curtain of vegetation; at one site the entrances of disused burrows of Wedge-tailed Shearwaters (*Puffinus pacificus*) were used, and once the occupied nest of a White-faced Storm-petrel (*Pelagodroma marina*). Eggs 4-5; incubation lasts c. 18 days; nestling period c. 30 days.

Movements. Resident, but with local post-breeding dispersal to other islands and coastal areas; on Kangaroo I birds are only present Jan-May.

Status and Conservation. Not globally threatened. CITES II. Generally common. Apparent gap in range at Great Australian Bight attributed to absence of suitable nesting sites. Moreover, mainland nesting areas are vulnerable to predation by rats, foxes, goannas and cats, so that all recent breeding records have been from offshore islets.

Bibliography. Baxter & Parker (1981), Blakers *et al.* (1984), Cain (1955), Dell & Johnstone (1977), Forshaw (1981b), Greenway, J.C. (1967), Jarman (1974), Lindsey, T.R. (1992), Macdonald (1988), Parker & Cox (1978), Pizzey & Doyle (1980), Saunders & de Rebeira (1985), Schodde & Tidemann (1986), Serventy & Whittell (1976), Simpson & Day (1996), Trounson & Trounson (1987), Vriends (1979), Warham (1955), Winslet (1981), Zomer (1987).

100. Orange-bellied Parrot

Neophema chrysogaster

French: Perruche à ventre orange German: Goldbauchsittich Spanish: Periquito Ventrinaranja

Taxonomy. *Psittacus chrysogaster* Latham, 1790, Tasmania. Monotypic.

Distribution. Coastal strip from SE South Australia to SC Victoria; Tasmania (all breeding now occurs on SW coast). Recorded near Sydney from late 1880's to 1907, with breeding reported.

Descriptive notes. 20-21 cm; mean 42 g. Similar to *N. chrysostoma* but much less yellow in face, crown and upperparts bright green, orange belly patch obvious, and tail green washed blue. Female has weaker, greener line on forehead. Immature duller than female, with smaller orange patch on belly.

Habitat. In breeding season, favoured sites are within 50 m of creekside or lagoon vegetation, where sedgelands adjoin open expanses of matted tussocks or buttongrass, with nesting in small adjacent copses. Birds forage on heath dominated by buttongrass (*Mesomelaena sphaerocephala*), mostly in areas burnt within

the past 15 years. In winter, saltmarsh much used, especially where *Arthrocnemum arbusculum*, *Salicornia quinqueflora* and *Suaeda australis* dominate, but also dunes and, apparently in times of shortage, open scrubland, paddocks, pastures and even golf courses.

Food and Feeding. Initially in summer, seeds of sedgeland plants such as *Lepyrodia tasmanica* and *Restio complanatus*, then seeds of *Boronia citriodora*, *B. parviflora*, *Helichrysum pumilium*, *Actinotus bellidioides* and buttongrass. Formerly birds took decaying kelp and seeds of *Poa billardieri* and berries of *Coprosma*. In early winter, seeds of the saltmarsh halophytes *Suaeda australis* and *Salicornia quinqueflora*, plus at high tide the pasture weeds *Chenopodium glaucum*, *Atriplex hastata* and *Rapistrum rugosum* and sometimes *Halosarcia halocnemoides* and *Frankenia pauciflora*, shifting mid-Jul to *Sclerostegia arbuscula* and later to *Arctotheca calendula*. Seeds of the introduced sea-rocket (*Cakile maritima*) and sheep's burr favoured in dunes.

Breeding. Nov-Dec. Nest in hollows 8-25 m up in living *Eucalyptus nitida* or, less often, *E. ovata*. Eggs 3-6; in captivity, incubation lasts 21 days, nestling period 5 weeks.

Movements. After breeding in SW Tasmania, birds move N in Mar-Apr through Bass Strait islands, notably King I where some birds stop over Apr-Jun and a few remain throughout the non-breeding period, but most wintering from late Mar to early Oct on SE Australian coast between the Coorong and Gippsland, the majority of the tiny population concentrating at Port Phillip Bay and the coastal dunes between Kingston and the Victoria border.

Status and Conservation. ENDANGERED. CITES I. A BirdLife "restricted-range" species. Population in 1990's probably 120 pre-breeding and c. 170 post-breeding. Destruction and alteration of vegetation combined with competition from other species and trapping of birds in winter quarters are blamed for the decline in the species, which was clearly more numerous around 1900 and apparently so even in the 1960's, and which appears to achieve good recruitment on breeding grounds; there is also evidence that disease may have played a role. A recovery programme focusing on winter habitat protection and restoration is under way, with particular input from the petrochemical developers (since 1978) of Point Wilson, in Port Phillip Bay.

Bibliography. Anderson *et al.* (1980), Blakers *et al.* (1984), Brouwer & Garnett (1990), Brown (1988), Brown & Wilson (1981, 1984), Brown, Holdsworth & Rounsevell (1994), Brown, Wilson *et al.* (1985), Cain (1955), Collar & Andrew (1988), Collar *et al.* (1994), Eckert (1990), Emison *et al.* (1987), Forshaw (1981a, 1981b), Garnett (1993), Green & McGarvie (1971), Greenway, J.C. 101. Turquoise Parrot

Neophema pulchella

French: Perruche turquoise German: Schönsittich Spanish: Periquito Turquesa
Other common names: Turquoise Grass-parakeet

Taxonomy. *Psittacus pulchellus* Shaw, 1792, New South Wales. Monotypic.

Distribution. SE Queensland to N Victoria, Australia.

Descriptive notes. 20 cm; 37-44 g. Forehead and face blue, shading to green on mid-crown and most upperparts; underparts from throat yellow, with vague orange tinge on belly; inner lesser wing-coverts chestnut-red; median and outer secondary coverts and outer secondaries pale turquoise blue; primary coverts and outer webs of primaries dark blue; tail green, dark at tip and laterally edged yellow. Female has greatly reduced blue on face, with whitish lores, sides of neck and breast green, no chestnut on wing. Immature duller.

Habitat. Open forest, woodland, native grassland, with marked preference for ecotones between open and closed habitats, e.g. heath-forest ecotone and adjacent farmland. In Victoria the species has a positive association with *Eucalyptus albens* which reflects its high use of rocky ridges in winter, moist flats and gullies from spring to autumn, and SE slopes year-round.

Food and Feeding. Generalized diet consisting of seeds, flowers and fruit of both native and introduced plants including grasses, composites, other herbs and shrubs: records include seeds or fruits of *Leucopogon microphyllus*, *Stellaria media*, *Briza minor*, *Hordeum marinum*, four species of *Danthonia*, *Stipa*, *Urtica urens*, *Hypochaeris glabra*, *Carthamus lanatus*, *Dianella revoluta*, *Geranium*, *Sisymbrium*, *Paspalum*, *Pulteneae procumbens*, *Dillwynia retorta*, *Brachyloma daphnoides*, *Hibbertia stricta*, flowers of *Grevillea alpina*, moss spore cases and spilt sorghum by roadsides.

Breeding. Aug-Dec, with one area producing records also in Apr-May, presumably second broods. Nest in hollow in tree (*Eucalyptus* in at least Victoria), stump, fence post or fallen log. Eggs 4-5 (2-6); incubation lasts c. 20 days; nestling period c. 4 weeks.

Movements. Apparently mainly sedentary but with local post-breeding dispersals and irregular local movements probably in response to rainfall. Reappearance in part of former range in 1994-1995 was judged a nomadic response to drought conditions elsewhere rather than a recolonization.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A dramatic decline to near-extinction occurred 1880-1920, attributed to the effects of habitat clearance and modification by introduced herbivores (cattle, sheep and rabbits), compounded by the impact of a major drought in 1902 and possibly by trapping; but after 1930 (and particularly after 1970) numbers recovered rapidly, and the species is currently locally common, albeit in disjunct areas. Good numbers in various reserves suggest that grazing indeed seriously disrupts foraging ability; however, the fall and rise in numbers was so sharp that possibly an epidemic was involved. In Victoria a lack of appropriate breeding hollows may be restricting population growth.

Bibliography. Blakers *et al.* (1984), Cain (1955), Chaffer & Miller (1946), Emison *et al.* (1987), Forshaw (1981b), Frith (1952b), Garnett (1993), Greenway, J.C. (1967), Hutchins (1985), Jack (1978), Jarman (1973), King (1978/79), Lindsey, T.R. (1992), López (1993), Macdonald (1988), Morris (1980, 1989), Pizzey & Doyle (1980), Quin (1990), Quin & Baker-Gabb (1993), Quin & Reid (1996), Rakos (1993b), Schodde & Tidemann (1986), Simpson & Day (1996), Slater (1978), Traill (1988), Traill *et al.* (1996), Trounson & Trounson (1987), Vriends (1979), Zomer (1987).

102. Scarlet-chested Parrot

Neophema splendida

French: Perruche splendide German: Glanzsittich Spanish: Periquito Espléndido

Other common names: Splendid Grass-parakeet, Scarlet-breasted Parrot

Taxonomy. *Euphema splendida* Gould, 1841, Western Australia.

Monotypic.

Distribution. Interior SW to SE Australia.

Descriptive notes. 19 cm; 36–44 g. Similar to *N. pulchella* but with red breast and no chestnut-red wing-patch. Female has paler blue face, with blue lores, breast green. Immature like female.

Habitat. Arid mallee- mulga scrublands, usually with sparse spinifex *Triodia* cover, with preference for recently burnt areas, in one case 3–5 years previously; also open *Eucalyptus gongylocarpa* woodland, *Casuarina cristata* woodland, vegetated ridges and open saltbush *Atriplex* plains.

Food and Feeding. Seeds of *Triodia* greatly favoured, with *Newcastelia dixonii*, *Halarogis*

odontocarpa, *Acacia* and *Stipa* seeds also recorded.

Breeding. Aug–Jan, but variable with conditions, especially rain. Nest in hole in tree, usually a dead part of a eucalypt, 2.5–8 m up; sometimes loosely colonial, or with loose concentrations of pairs in a few hectares. Eggs 3–5, rarely 6; incubation lasts c. 18 days; nestling period c. 30 days.

Movements. Probably nomadic and certainly irruptive, presumably in response to favourable climatic conditions. Some more regular movements may occur: in E South Australia flocks recorded in the period Apr–Aug of several consecutive years, with birds then disappearing, presumably to breed.

Status and Conservation. VULNERABLE. CITES II. Birds are generally rare, but large numbers occur in periodic irruptions, e.g. 1939 and 1966, suggesting that the species is adapted to build up numbers rapidly in favourable conditions, and indeed that it may not be as rare as often thought in the remoter parts of its range. However, changes in vegetation owing to altered fire regimes may have had an effect on abundance, and greater availability of water (for livestock) may have disadvantaged the species against more water-dependent parrots, notably *Neopsephotus bourkii*. No fewer than 25,000 birds are held in captivity in Australia.

Bibliography. Andrew & Palliser (1993), Blakers *et al.* (1984), Brouwer & Garnett (1990), Cain (1955), Collar & Andrew (1988), Collar *et al.* (1994), Fitzherbert & Baker-Gabb (1988), Ford (1971), Forshaw (1981a, 1981b), Garnett (1993), Greenway, J.C. (1967), Henderson (1977), Hutchins (1985), Jarman (1968), Joseph (1976), King (1978/79), Larzelere (1996), Lindsey, T.R. (1992), Low (1994b), Macdonald (1988), Pizzey & Doyle (1980), Pollard (1965), Robinson *et al.* (1990), Schodde & Tidemann (1986), Serventy & Whittell (1976), Simpson & Day (1996), Slater (1978), Storr (1977, 1986, 1987), Tronson & Tronson (1987), Vriends (1979), Zomer (1987).

Genus *LATHAMUS* Lesson, 1830

103. Swift Parrot

Lathamus discolor

French: Perruche de Latham German: Schwalbensittich Spanish: Periquito Migrador

Taxonomy. *Psittacus Discolor* J. White, 1790, New South Wales.

Monotypic.

Distribution. Tasmania and possibly Flinders I in Bass Strait. Winters in E & SE Australia.

Descriptive notes. 25 cm; 50–74 g. Green, with forehead and front of face, chin and throat red outlined with yellow except for deep blue patch on mid-crown; underwing-coverts, undertail-coverts, shoulder and lesser wing-coverts red, outer secondary coverts tinged blue, primary coverts and primaries dark bluish; some red feathers on flanks, but individually variable; tail dark reddish above, dull grey below. Female similar. Immature duller, with less red.

Habitat. In breeding season eucalypt forest, especially those with blue gum (*Eucalyptus globulus*), but also gardens and parks. In winter remnant open forest areas within agricultural land, parklands and suburbs.

Food and Feeding. Pollen and nectar, especially from *Eucalyptus* blossoms, in particular blue gum, but also *Banksia* and *Xanthorrhoea* flowers, supplemented by insects and their larvae, notably psyllid lerps, fruit, berries and seeds. On mainland dependent on winter flowering eucalypts, notably *E. sideroxylon*, *E. leucoxylon*, *E. albens* and *E. ovata*, and on *E. viminalis* in autumn.

Breeding. Oct–Jan. Nest in hole 7–20 m up in tree, usually a mature or senescent blue gum, often semi-colonially, sometimes with *Neophema chrysostoma*; once in crevice in wall. Eggs 3–5; in captivity, incubation lasting c. 20 days, and nestling period c. 10 weeks.

Movements. Austral migrant, moving to Australian mainland Jan–May, a few birds remaining in Tasmania year-round; on wintering grounds irregularly dispersive and nomadic, following eucalypt flowering and psyllid lerp infestations, except at centre of distribution in S & C Victoria, unless occasional widespread flowering allows large-scale movements throughout winter range.

Status and Conservation. VULNERABLE. CITES II. A BirdLife “restricted-range” species. Abundance of *E. globulus* greatly reduced in Tasmania, and similar loss of mature, productive winter food trees; some illegal trapping has also occurred. Population of 1320 breeding pairs, 1988/1989, with an end-of-season population of over 5000 birds, but forest clearance within range continues and some birds are still trapped illegally for trade, though the species does poorly in captivity.

Bibliography. Blakers *et al.* (1984), Brouwer & Garnett (1990), Brown (1989), Collar *et al.* (1994), Condon (1968), Emison *et al.* (1987), Forshaw (1981b), Garnett (1993), Green (1969, 1977a), Green & McGarvie (1971), Hindwood & McGill (1958), Hindwood & Sharland (1964), Houston (1982), Lendon (1951), Lindsey, T.R. (1992), Macdonald (1988), Pizzey & Doyle (1980), Schodde & Tidemann (1986), Simpson & Day (1996), Storr (1973), Tavistock (1936), Thomas (1970), Tronson & Tronson (1987), Vriends (1979).

Genus *MELOPSITTACUS* Gould, 1840

104. Budgerigar

Melopsittacus undulatus

French: Perruche ondulée German: Wellensittich

Spanish: Periquito Común

Other common names: Shell Parakeet

Taxonomy. *Psittacus undulatus* Shaw, 1805, New South Wales.

Monotypic.

Distribution. Australia, mainly away from coasts and absent from Cape York Peninsula. Feral in C Florida, USA.

Descriptive notes. 18 cm; 26–29 g. Cere blue, forehead, front of face and throat pale yellow, last with line of black spots; lower malar area purple; mid-crown and area below eye back to nape barred black and pale yellow, broadening to become scalloping on mantle and wing-coverts; underparts, underwing-coverts, lower back and rump light green; tail dull bluish, lateral feathers with a central yellow band. Female has brownish cere. Immature duller with barring on forehead and no black spots on throat.

Habitat. Inhabits a wide variety of open habitats including open forest, savanna, lightly

wooded grasslands, mallee, farmland, riparian growth, dry scrubland and open plains, even penetrating *Alga (Acacia aneura)* deserts; although capable of surviving long periods without water, birds are rarely found far from a source.

Food and Feeding. Grass and chenopod seeds taken on or near ground, the number of species and proportions varying with season and part of range. In inland mid-eastern Australia birds were found to eat only seeds of ground vegetation, from 0.5 to 2.5 mm in length, with up to 39 species involved; at one site *Astrelba* spp. were dominant in the diet, while further inland a wider array was taken, including *Boerhavia diffusa*, *Atriplex* and *Astrelba pectinata*, in the hot months, with *Iseilema* important in the colder period. Occasionally attacks ripening grain crops.

Breeding. Jun–Sept in N of range, Aug–Jan in S, but any time of year after substantial rains, and where conditions permit there may be two breeding seasons in a particular year. Often communal. Nest in hollow in tree, stump, fence post or fallen limb. Eggs 4–6 (up to 8); incubation lasts c. 18 days; nestling period c. 30 days.

Movements. In parts of range areas exist in which seasonal production of food is regular, and others where the supply is stable for extended periods, so some populations relatively predictable on seasonal basis; in far S of range birds only present Sept–Jan. Elsewhere fairly nomadic according to water and seeding grass. In times of drought, birds move wherever conditions are more favourable, but then may be confined to these refuges as the drought intensifies, only recolonizing old areas once rainfall permits it.

Status and Conservation. Not globally threatened. Abundant; in favourable years in certain places flocks darken the sky and the weight of perching birds has broken eucalypt branches 4 cm in diameter. Capable of considerable fluctuations in population levels depending on climatic conditions over several years, and these levels are probably driven as much by short-term breeding success as by immigration. Livestock farming in many parts of interior Australia has required widespread artificial water provision, and some populations appear to have increased permanently as a result. Generally, however, the species is found in small parties, especially at the edges of its range.

Bibliography. Baltz & Clark (1994, 1996), Bird (1990), Blakers *et al.* (1984), Brereton (1977), Brockway (1962, 1964a, 1964b), Bürkle (1997), Cade & Dybas (1962), Chinner (1977), Clark *et al.* (1981), Danielle & Murray (1986), Ferrell & Baptista (1982), Forshaw (1981b), Hinde & Putman (1973), Hutchison (1977), Lea & Gray (1935), Lever (1987), Lindsey, T.R. Genus *PEZOPORUS* Illiger, 1811

105. Ground Parrot

Pezoporos wallicus

French: Perruche terrestre

German: Erdsittich

Spanish: Perico Terrestre

Other common names: Swamp Parrot

Taxonomy. *Psittacus wallicus* Kerr, 1792, New South Wales.

Two subspecies recognized.

Subspecies and Distribution.

P. w. flaviventris North, 1911 - coastal SW Australia.

P. w. wallicus (Kerr, 1792) - coastal SE Australia and Tasmania.

Descriptive notes. 30 cm; mean 130 g. Red frontal band; plain green on face and breast; crown green with black streaks; upperparts green mottled black with yellow buff chevrons and spots; flanks and belly yellowish barred black; tail dull green with yellow notches on outer vanes. Female has pale yellow underwing stripe. Immature lacks red frontal band and face and breast are marked black. Race *flaviventris* has bright yellow on belly with reduced barring.

Habitat. Generally found in coastal graminoid and adjacent montane heathlands up to 1800 m, optimally 5–10 years after burning has taken place in heath dominated by shrubs, 15–18 years after burning in heath dominated by sedges and grass trees. Within heaths, birds frequent drier habitats from mid-autumn to late spring, wetter ones in summer and early autumn, apparently in response to

seed availability. Birds also occur, perhaps only seasonally, in estuarine flats, swampy ground with reed clumps, grasslands and pastures. In Tasmania, buttongrass moorland, consisting of a mosaic of graminoid heathland, scrub and sedgelands.

Food and Feeding. Seeds and green shoots of grasses and herbs, with a preference for buttongrass (*Mesomelana sphaerocephala*) but also *Leptocarpus tenax*, *Anthistiria*, *Paspalum*, *Compressum* and *Xanthorrhoea*. In regurgitated crop samples, 35 different seed types were identified, 16 monocotyledons (e.g. Cyperaceae, Restionaceae), 19 dicotyledons (e.g. Rutaceae,

Eupacridaceae, Fabaceae). Although opportunistic feeder, bulk of diet on Tasmania probably supplied by Restionaceae.

Breeding. Generally Jul-Dec; once Mar. Nest a shallow scrape in soil lined with stalks or leaves, often at the base of a tussock or bush and hidden in a tunnel or chamber of vegetation, in Queensland the key plants being *Empodisma minor*, *Xanthorrhoea fulva* and *Banksia oblongifolia*. Of 20 found, 18 in dry heath, 2 on dry/wet ecotone, and all in areas not burnt for at least 4 years; minimum density was 1-1.3 nests per 10 ha. Eggs 3-4, but up to 6 recorded in Tasmania; incubation c. 21 days; young leave the scrape after 20-28 days, often a little before fully capable of flight. Egg failure high at 22-31%. On average a pair produced 1.9 fledglings per nest.

Movements. Reputedly sedentary, based on view that it is a weak flier, but actually flight is powerful and at least on Tasmania it is likely that altitudinal migration occurs, since higher areas in which birds are recorded are snow-covered in winter. Substantial post-breeding dispersal of young birds occurs, e.g. into marginal unoccupied habitat such as swamps and recently burnt heath; individuals have moved 120 km and some winter records have been far from known breeding areas. However, failure to recolonize some now well-preserved pockets of habitat suggests that little nomadism occurs.

Status and Conservation. Not globally threatened, CITES I. Loss of habitat to urban and agricultural development, including inappropriate burning and establishment of pine plantations, along the seaboard has rendered this species relatively rare, and its range is greatly restricted and discontinuous, with high degree of endangerment in Western and South Australia. Although the population in Tasmania is probably over 100,000 birds, that in SE Australia is much lower, with an estimated 2900 birds in Queensland, and that in SW Australia (entire race *flaviventris*) only 378. Peak densities are 4-6 birds per 10 ha, but only occur 5-8 years after heathland burnt (15 years after burning, few or no parrots are believed to occur); similar situation in Tasmania, though in Western Australia birds favour older heaths, whose much lighter annual rainfall means that recovery after fire is much slower. Thus habitat management involving burning on an 8-10 year cycle is necessary in SE range to prevent invasion of woody plants; and/or the control of grazing to ensure sufficient growth in food-plants and cover. Tasmania now the stronghold. All SW populations (race *flaviventris*) are now within Fitzgerald R and Cape Arid National Parks, but this does not give full protection against fire; an estimated third of the parrot population in the former was lost in a fire in Dec 1989, and both fox predation and habitat deterioration through the spread of soil fungi *Phytophthora* may be causing problems.

Bibliography. Baker & Whelan (1994), Blakers *et al.* (1984), Bryant (1991, 1992, 1994), Burbidge (1997), Burbidge, McNeen *et al.* (1990), Burbidge, Watkins & McNeen (1989), Collar & Andrew (1988), Condon (1968), Emison *et al.* (1987), Forshaw (1981a, 1981b), Garnett (1993), Gosper (1995), Greenway, J.C. (1967), Hinsby (1948), Hodges (1961), Jordan (1988), King (1978/79), Leeton *et al.* (1994), Lindsey, T.R. (1992), Low (1994b), Macdonald (1988), McCall (1957), McFarland (1988, 1991a, 1991b, 1991c, 1991d, 1992), Meredith *et al.* (1984), Pizzey & Doyle (1980), Reid *et al.* (1975), Schodde & Tidemann (1986), Schulz & Kristensen (1994), Serventy & Whittell (1976), Simpson & Day (1996), Slater (1978), Storr (1973), Trounson & Trounson (1987), Watkins (1985), Watkins & Burbidge (1992).

Genus *GEOPSITTACUS* Gould, 1861

106. Night Parrot

Geopsittacus occidentalis

French: Perruche nocturne

German: Höhlensittich

Spanish: Perico Nocturno

Taxonomy. *Geopsittacus occidentalis* Gould, 1861, West Australia.

Frequently placed in genus *Pezoporus*, and is undoubtedly very closely related. Monotypic.

Distribution. Interior of W & C Australia.

Descriptive notes. 23 cm. Mottled dull green and black above and below, with green ear-coverts and plain yellow belly and undertail-coverts; flight-feathers and tail blackish brown, outer tail feathers with yellowish notches. Immatures reportedly dull and plain.

Habitat. Spinifex (*Triodia*) hummock grassland on stony ridges and rocky breakaways, chenopod low shrub steppe and samphire around dry salt pans; reported pitching into dense lignum (*Muehlenbeckia*) when flushed. Not all recent sightings have been in spinifex plains, which may only be used when seeding; patch burning to create firebreaks, allowing

mature spinifex to develop in a mosaic, appears to have created favourable conditions.

Food and Feeding. Seeds of spinifex found in one specimen. In a recent sighting, circumstance suggests feeding on seeds of *Enneapogon purpurascens*.

Breeding. Nest is a platform of sticks on or near the ground in an enlarged cavity tunnelled into a dense tussock. Eggs reportedly 4.

Movements. Possibly a wanderer, possibly sedentary, perhaps depending on locality or climate; reported in past that numbers fluctuate with season, and the collection of 16 specimens in N South Australia in 1870's may have reflected a local irruption, possibly reflecting favourable climatic conditions or displacement from newly settled stocklands elsewhere. The notion that birds move seasonally between spinifex grassland and chenopod shrublands determined by spinifex seed availability is not borne out by recent records.

Status and Conservation. CRITICALLY ENDANGERED, CITES I. Habitat degradation caused by altered fire regimes and livestock grazing, compounded by predation by introduced cats and foxes and possibly by reduction of water availability due to camels, may all have contributed to the decline of this species, although clearly its nocturnal habits and inhospitable habitat greatly obscure an understanding of both past and present status. Formerly considered extinct. Seven sightings, 1992-1993, indicate small numbers survive. Recent records suggest that sensitive land management, with patch burning of spinifex, moderate livestock densities and low levels of exotic predators, may contribute the conditions under which birds survive.

Bibliography. Andrew, D. (1990), Andrews (1883), Blakers *et al.* (1984), Boles *et al.* (1994), Brouwer & Garnett (1990), Collar & Andrew (1988), Collar *et al.* (1994), Davies *et al.* (1988), Fitzherbert & Baker-Gabb (1988), Forshaw (1981a, 1981b), Forshaw *et al.* (1976), Fullick (1991, 1994a), Garnett (1993), Garnett *et al.* (1993), Greenway, J.C. inches 4
cm 10

Tribe PSITTACULINI

Genus *PSITTINUS* Blyth, 1842

107. Blue-rumped Parrot

Psittinus cyanurus

French: Perruche à croupion bleu **German:** Rotachselpapagei **Spanish:** Lorito Dorsiazul
Other common names: Blue-rumped Parakeet

Taxonomy. *Psittacus cyanurus* J. R. Forster, 1795, Malacca.

Three subspecies recognized.

Subspecies and Distribution.

P. c. cyanurus (J. R. Forster, 1795) - S Myanmar and S Thailand S through W Malaysia, Sumatra and Borneo; apparently in Indochina in 19th century.

P. c. abbotti Richmond, 1902 - Simeulue and Sumat, off NW Sumatra.

P. c. pontius Oberholser, 1912 - Mentawai Is., off W Sumatra.

Descriptive notes. 18 cm. Upper mandible red; head lavender blue; underparts greyish olive with a yellow pectoral tuft, shading ventrally to yellowish green; mantle, upper back and primary coverts indigo-black; lower back to uppertail-coverts bright blue; rest of wing green edged yellow; flanks and underwing-coverts red; tail greenish yellow. Female has brownish bill, brown head with coppery crown, yellowish green below and small blue dorsal patch. Immature has grass-green head and body with yellow fringes to wing-coverts, males soon developing red upper mandible. Race *pontius* larger; *abbotti* larger with greenish yellow underparts, green mantle, back and rump, female has green head.

Habitat. Plains-level primary and logged rain forest, forest edge and clearings, oil-palm and coconut plantations, exceptionally mangroves, up to 700 m. Observed mainly in dry forest areas and kerangas, Kalimantan.

Food and Feeding. Poorly documented. Mesocarp of oil-palm fruits extracted individually from the bunch, fruits of *Macaranga rhizinoides* and seeds of *Parkia speciosa*.

Breeding. Nest inspection recorded Nov and Feb, with eggs in May; Jun-Sept in Borneo. Nest in a small natural hole 30 m or more in live forest tree, including *Shorea*. Eggs 3.

Movements. Long-distance, possibly nomadic dispersal suspected: birds may have very large home ranges or else follow seed-flushes opportunistically; evidence of seasonal aggregations in Kalimantan, and apparently only an irregular summer visitor to S Myanmar.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. Regarded as near-threatened owing to its restriction to lowland forest in Greater Sundas, but ability to exploit oil-palms suggests it is relatively secure. Common in primary habitat, becoming uncommon in disturbed forest and plantations. Widespread in Kalimantan and Brunei, considered scarce by some and not uncommon by others; huge concentrations in Mar recorded in one area. Now sparse in S Thailand doubtless owing to deforestation. As many as 3180 entered trade in 1990, almost all out of Malaysia, with no indication of effects on overall population levels.

Bibliography. Andrew (1992), Anon. (1993), Baker (1934), Chasen & Hoogerwerf (1941), Danielsen & Heegaard (1995), Duckworth & Kelsh (1988), Harris (1993b), Holmes (1996), Holmes & Burton (1987), Jordan (1993), Kidd (1978), Lekagul & Round (1991), MacKinnon & Philipps (1993), Mann (1987), van Marle & Voous (1988), Medway & Wells (1976), Nash & Nash (1988), Round (1988), Smythies (1981, 1986), Sweeney (1996g, 1997b), Thompson (1966), Vuthipong (1992), Ward & Wood (1967).

Genus *PSITTACELLA* Schlegel, 1873

108. Brehm's Tiger-parrot

Psittacella brehmii

French: Perruche de Brehm **German:** Brehmpapagei **Spanish:** Lorito-tigre de Brehm
Other common names: Brehm's Parrot

Taxonomy. *Psittacella Brehmii* Schlegel, 1873, mountainous interior, 4000-5000 feet (c. 1200-1500 m), west coast of Geelvink Bay = Arfak Mountains.

Four subspecies recognized.

Subspecies and Distribution.

P. b. brehmii Schlegel, 1873 - Vogelkop, NW New Guinea.

P. b. intermixta Hartert, 1930 - Weyland and Snow Mts and Mt Goliath, C Irian Jaya.

P. b. harterti Mayr, 1931 - Huon Peninsula, NE New Guinea.

P. b. pallida A. B. Meyer, 1886 - central mountains of Papua New Guinea.

Descriptive notes. 24 cm; 94-120 g. Bill brownish grey with pale cutting edges; head and throat chocolate brown with vertical yellow line on side of neck; nape, mantle, rump and uppertail-coverts evenly barred black and green; wings dull green with blue leading edge and brownish black flight-feathers; breast to belly lime green; vent and undertail-coverts red; tail green above, brown below. Female lacks yellow line on neck, and has black and yellow barring on upper breast. Immature like female with breast narrowly barred green and dull yellow. Race *intermixta* larger, paler and yellower;

harterti like nominate but head more olive; *pallida* more yellowish, some with a blue wash on belly.

Habitat. Interior of montane *Podocarpus* and *Nothofagus* forest and edge, low scrubby regrowth and vegetation bordering open areas, often descending into grass; generally at 1500-2600 m, but up to 3800 m on Huon Peninsula in absence of *P. picta*.

Food and Feeding. Buds, fruits and leaves of *Homalanthus*, hard berries, small hard seeds, and fruits of *Podocarpus* have been recorded, and lerps suspected as often seen searching leaves.

Breeding. Slight gonadal development in Aug; breeding condition bird in Jan; nestlings May-Jun. **Movements.** No information.

Status and Conservation. Not globally threatened. CITES II. Fairly common and widespread throughout range. Regularly recorded around Tari Gap, Papua New Guinea.

Bibliography. Andrew (1992), Anon. (1994a), Beehler (1978b), Beehler *et al.* (1986), Coates (1985), Diamond (1972a), Frith & Frith (1992), Gilliard & LeCroy (1961), Gyldenstolpe (1955a), Hartert (1930), Hopkins (1992), Mayr & Gilliard (1954), Mayr & Rand (1937), Rand (1942b), Rand & Gilliard (1967), Ripley (1964), Rothschild (1931), Sims (1956).

109. Painted Tiger-parrot

Psittacella picta

French: Perruche peinte **German:** Braunscheitelpapagei **Spanish:** Lorito-tigre Pintado
Other common names: Painted Parrot, Timberline Tiger-parrot

Taxonomy. *Psittacella picta* Rothschild, 1896, Mount Victoria, 5000-7000 feet (c. 1500-2100 m), Owen Stanley Range, New Guinea.

Three subspecies recognized.

Subspecies and Distribution.

P. p. lorentzi van Oort, 1910 - Snow Mts, C Irian Jaya.

P. p. excelsa Mayr & Gilliard, 1951 - montane C Papua New Guinea.

P. p. picta Rothschild, 1896 - montane SE Papua New Guinea.

Descriptive notes. 19 cm; 48-68 g. Bill silver-grey; entire crown rufous-brown, face greyish brown, with yellow collar over neck to sides of throat; throat and upper breast blue shading to green on belly; undertail-coverts red; mantle and back green barred black, shading to yellow barred black on rump; uppertail-coverts red; wings and tail green, duller below. Female has dull greenish blue face surrounded with rufous brown of crown extending on sides of neck to replace yellow collar; breast and upper belly barred yellow and black. Immature like female but head all brown. Race *excelsa* has olive-brown crown; *lorentzi* has blue-green

face, no red on uppertail-coverts.

Habitat. Subalpine shrubby and low substage within forest, preferably adjoining open grassland from which birds are sometimes flushed, from 2500 m to treeline, rarely descending as low as 1370 m.

Food and Feeding. Seeds and small hard berries, fruits of *Dacrydium*. Feeds in small trees and shrubs.

Breeding. Breeding condition birds in Jun and Aug, with juvenile collected in Oct.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Widespread but generally scarce, though locally common.

Bibliography. Andrew (1992), Beehler (1978b), Beehler *et al.* (1986), Clapp (1986), Coates (1985), Coates & Lindgren (1978), Diamond (1972a), Donaghy (1970), Greensmith (1975), Gregory (1995a, 1995b), Mayr & Rand (1937), Rand (1942b), Rand & Gilliard (1967), Ripley (1964), Sims (1956), Sujatnika *et al.* (1995).

110. Modest Tiger-parrot

Psittacella modesta

French: Perruche modeste **German:** Olivpapagei **Spanish:** Lorito-tigre Modesto
Other common names: Modest Parrot, Barred Little Tiger-parrot

Taxonomy. *Psittacella [sic] modesta* Schlegel, 1873, mountainous interior, 4000-5000 feet (c. 1200-1500 m), west coast of Geelvink Bay = Arfak Mountains.

Three subspecies recognized.

Subspecies and Distribution.

P. m. modesta Schlegel, 1873 - Vogelkop, NW New Guinea.

P. m. subcollaris Rand, 1941 - N slopes of Snow Mts E to C Papua New Guinea.

P. m. collaris Ogilvie-Grant, 1914 - S slopes of Snow Mts.

Descriptive notes. 14 cm; 42-43 g. Head dark brown, darkest on crown, with vague olive-yellow mottling on nape; colour extends onto mantle and shades to paler olive brown on throat and breast, and to green on belly; undertail-coverts red; back, wings and tail dull green, blue on bend of

wing, underwing-coverts yellowish green; underside of tail dusky grey. Female has breast barred orange and dark brown. Immature similar to female. Race *collaris* has yellow mottling on nape developed into irregular collar; *subcollaris* similar but with narrower, brighter collar.

Habitat. Montane forest, second growth and forest edge at 1700-2800 m; commonly seen in scrub adjacent to grasslands. Where overlap with *P. madaraszii* occurs, occupies generally higher elevations.

Food and Feeding. Witnessed feeding on small fruits; seeds and pieces of hard berries in stomachs.

Breeding. Male in breeding condition in Jun. No further information available.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Locally common but very unobtrusive.

Bibliography. Andrew (1992), Beehler *et al.* (1986), Campbell (1981), Coates (1985), Diamond, J.M. (1972a, 1985), Frith & Frith (1992), Gilliard & LeCroy (1961), Greensmith (1975), Gregory (1995a, 1995b), Mayr & Rand (1937), Rand (1942b), Rand & Gilliard (1967), Sims (1956), Sujatnika *et al.* (1995).

111. Madarasz's Tiger-parrot

Psittacella madaraszii

French: Perruche de Madarasz **German:** Madaraszpapagei **Spanish:** Lorito-tigre de Madarasz
Other common names: Madarasz's Parrot, Plain-breasted Little Tiger-parrot

Taxonomy. *Psittacella madaraszii* A. B. Meyer, 1886, south-eastern spurs of the Owen Stanley Range, New Guinea.

Four subspecies recognized.

Subspecies and Distribution.

P. m. major Rothschild, 1936 - Weyland Mts and N slopes of Snow Mts, WC New Guinea.

P. m. hallstromi Mayr & Gilliard, 1951 - C New Guinea.

P. m. huonensis Mayr & Rand, 1935 - Huon Peninsula.

P. m. madaraszii A. B. Meyer, 1886 - SE New Guinea.

Descriptive notes. 14 cm; 34-44 g. Very similar to *P. modesta* but head paler and marked yellow on lower face, with yellow mottling of nape never forming a collar and brown of throat merging into green of underparts on breast rather than on belly. Female replaces brown with green, with bluish forehead and black-and-green barring extending from mid-crown to uppertail-coverts, base colour turning orange-red on nape and yellow on rump (one seen with chocolate brown patch from nape to hindneck, no barring, little blue on forehead). Immature like female. Race *huonensis* male has more yellowish crown.

female lacking orange on nape; *hallstromi* male darker and female nape brighter than nominate; *major* slightly larger.

Habitat. Mid-montane forest and its scrubby edges, secondary growth and partly cleared areas, mainly at 1150-2500 m.

Food and Feeding. Fruits, seeds, hard berries and leaf pulp recorded; birds seen feeding at the bases of arboreal ant plants.

Breeding. Breeding condition birds in Jun and Sept.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Apparently uncommon, but this perhaps an artefact of its great unobtrusiveness. Regularly recorded below Tari Gap, Papua New Guinea.

Bibliography. Andrew (1992), Anon. (1994a), Beehler (1978b), Beehler *et al.* (1986), Bishop (1987), Coates (1985), Coles (1995), Diamond (1972a), Gregory (1995a, 1995b), Mayr & Rand (1937), Rand & Gilliard (1967), Rowland (1995), Sims (1956).

Genus GEOFFROYUS Bonaparte, 1850

112. Red-cheeked Parrot

Geoffroyus geoffroyi

French: Perruche de Geoffroy **German:** Rotkopfpapagei **Spanish:** Lorito Carirrojo

Taxonomy. *Psittacus Geoffroyi* Bechstein, 1811, New Holland; error = Timor.

Genus has occasionally been merged into *Psittinus*. Proposed races *sumbavensis* and *tjindanae* are synonyms of *floresianus*; *stresemanni* of *rhodops*; *explorator* too may be synonymous with *rhodops*. Sixteen subspecies recognized.

Subspecies and Distribution.

G. g. cyanicollis (S. Müller, 1841) - N Moluccas.

G. g. obiensis (Finsch, 1868) - Obi group, NC Moluccas.

G. g. rhodops (Schlegel, 1864) - S Moluccas.

G. g. explorator Hartert, 1901 - Seram Laut Is (E of Seram).

G. g. keyensis Finsch, 1868 - Kai Is.

G. g. floresianus Salvadori, 1891 - W Lesser Sundas.

G. g. geoffroyi (Bechstein, 1811) - E Lesser Sundas.

G. g. timorlaensis A. B. Meyer, 1884 - Tanimbar Is.

G. g. pucherani Souacé, 1856 - W Papuan Is and NW New Guinea.

G. g. minor Neumann, 1922 - N New Guinea.

G. g. jobiensis (A. B. Meyer, 1874) - Yapen and Meos Num, Geelvink Bay.

G. g. mysoriensis (A. B. Meyer, 1874) - Biak and Numfor, Geelvink Bay.

G. g. orientalis A. B. Meyer, 1891 - Huon Peninsula (NE New Guinea).

G. g. sudestiensis De Vis, 1890 - Misima and Tagula in Louisiade Archipelago.

G. g. cyanicarpus Hartert, 1899 - Rossel in Louisiade Archipelago.

G. g. aruensis (G. R. Gray, 1858) - Aru Is, S New Guinea, E Papuan islands and extreme N Queens-land.

Descriptive notes. 21-27 cm; 130-180 g. Green above, yellowish green below; upper mandible red, lower black; head red except mid- to hindcrown pale violet blue; dull red stain on median wing-coverts; underwing-coverts blue. Female has entire head dusky brown, with brownish grey bill. Immature has green head with brown tinges, dull bill. Race *floresianus* darker with violet extending onto nape; *cyanicollis* with long blue collar; *obiensis* with wider blue collar, back brownish; *rhodops* large, dark; *explorator* like *rhodops* but female with paler forecrown; *keyensis* large and yellowish, with paler tail; *timorlaensis* similar but smaller;

aruensis like *floresianus* but paler; *orientalis* similar but paler violet crown; *sudestiensis* also similar but yellowish, without brown wing-coverts; *cyanicarpus* with mauve-violet on face, blue edge to wing; *minor* like *aruensis* but back brownish; *jobiensis* similar but back more reddish; *mysoriensis* also similar but violet blue extends over hindneck and red over throat; *pucherani* like *minor* but with little brown on wing-coverts, underwing-coverts dark blue.

Habitat. Lowlands generally to c. 800 m, sometimes higher (e.g. 1400 m, Flores and Lombok), in primary and secondary wet and monsoon forest, being much less frequent in open habitat, but in Lesser Sundas and on a few other islands seems to be commoner in drier open coastal country including savanna woodland, coconut plantations as well as gardens, mangroves, nypa forest, freshwater swamp- and dryland forest and small offshore islands.

Food and Feeding. Seeds, nuts, fruits, berries, flower buds, blossoms all recorded, but seeds within fruit, such as *Eucalyptus papuana*, *Casuarina papuana* and *Alpinia*, appear important; also seen taking fruit of the savanna tree *Antidesma gaisambulla* and *Ganophyllum falcatum*, and mistletoes.

Breeding. Apr-Aug in Lesser Sundas; Feb in NW New Guinea; Oct in NE New Guinea; Apr and Oct-Dec in S New Guinea (probably in most of year throughout island); Aug-Dec in Australia. Nest in hole excavated by female in dead trunk or branch, 4-25 m up; on Sumba keeps apart from nesting associations made by other psittacids; in Australia noted to nest often at forest edge, or in *Melaleuca* or *Pandanus* woodland adjacent to rain forest. Eggs 3; incubation by female; young stay with parents perhaps into second year, possibly assisting at nest.

Movements. Substantial daily flights are made, but no hard evidence of seasonal movements.

Status and Conservation. Not globally threatened. CITES II. Common to abundant throughout much of range; estimated at 30 birds/km² in one area of New Guinea, and at 80 birds/km² on Halmahera. Common on Sumba, Bacan, Obi and the coast of Seram, less so in interior hills, and this diminution of numbers with elevation applies apparently throughout range. Moderate numbers throughout Buru. Population of race *aruensis* in N Australia very restricted and feared likely to suffer from loss of suitable old nest-trees through late dry-season fires.

Bibliography. Beehler *et al.* (1986), Bell (1970b, 1975, 1982), Blakers *et al.* (1984), Bowler & Taylor (1989), Clapp (1987b), Cleland (1968), Coates (1985), Coates & Bishop (1997), Diamond (1972a), Forshaw (1966, 1981b), Garnett (1993), Hoogerwerf (1971), Jepson (1993), Lambert (1994b), Linsley (1995), Low (1997d), MacKinnon *et al.* (1995), Marsden (1995), Mayr (1944b), Mayr & Rand (1937), Milton (1988), Rand (1942a), Rand & Gilliard (1967), Rensch (1931), Rinke (1997b), Smiet (1985), White & Bruce (1986).

113. Blue-collared Parrot

Geoffroyus simplex

French: Perruche à col bleu **German:** Blauhalspapagei **Spanish:** Lorito Acollarado
Other common names: Simple/Lilac-collared Parrot

Taxonomy. *Pionias simplex* A. B. Meyer, 1874, Arfak Mountains, 3500 feet (c. 1000 m), New Guinea.

Genus has occasionally been merged into *Psittinus*. Two subspecies recognized.

Subspecies and Distribution.

G. s. simplex (A. B. Meyer, 1874) - Vogelkop (NW New Guinea).

G. s. buergeri Neumann, 1922 - Snow Mts E to Owen Stanley Range, New Guinea.

Descriptive notes. 22 cm; 161 g. Green, more yellowish on underparts, with broad, full but indistinct greyish blue collar; bronze stain on median wing-coverts; underwing-coverts dark blue; tail dusky yellow below; bill grey-black. Female lacks collar but has blue tinge to crown. Immature like female. Race *buergeri* has collar more lilac-coloured, deeper blue underwing-coverts.

Habitat. Mid-montane oak forest at 600-2000 m, favouring drier ridges.

Food and Feeding. Seeds of *Castanopsis* and *Lithocarpus* oaks are particularly favoured, and small seeds found in stomachs, but regularly visits flowering trees presumably for nectar and blossoms.

Breeding. Jan and Oct. Nest recorded in hole 10 m up in large rotten stump, with three young.

Movements. Strongly nomadic, fairly often penetrating lowlands to sea-level, and sometimes ranging up to 2300 m, consistently forming larger flocks than *G. geoffroyi*. Only seen in flocks flying high over Crater Mountain forest.

Status and Conservation. Not globally threatened. CITES II. Generally rather scarce to fairly common, but extremely shy.

Bibliography. Andrew (1992), Beehler (1978b), Beehler *et al.* (1986), Coates (1985), Diamond (1972a), Filewood (1974a), Gregory (1995a, 1995b), Mack & Wright (1996), Pratt (1982), Rand (1942b), Rand & Gilliard (1967).

114. Singing Parrot

Geoffroyus heteroclitus

French: Perruche hétéroclite **German:** Bismarckpapagei **Spanish:** Lorito Heteróclito
Other common names: Song Parrot

Taxonomy. *Psittacus Geoffroyi heteroclitus* Hombron and Jacquinot, 1841, San Jorge and Ysabel Islands, Solomon Islands.

Genus has occasionally been merged into *Psittinus*. Two subspecies recognized.

Subspecies and Distribution.
G. h. heteroclitus (Hombron & Jacquinot, 1841) - Bismarck Archipelago E to Solomons (except Rennell).
G. h. hyacinthinus Mayr, 1931 - Rennell I.
Descriptive notes. 25 cm; 150-195 g. Upper mandible yellow, lower grey; head yellow, brighter around forehead shading duller on nape, and bordered by a broad, full dove-grey collar; rest of body green, more yellowish on underparts, but with reddish stain on median wing-coverts, deep blue on underwing-coverts and underside of tail dusky yellow. Female has crown and face olive-grey, grey upper mandible, rest of body as in male. Immature like female but crown pale grey. Race *hyacinthinus* has broader grey collar, blue in bend of wings and primaries.
Habitat. Lowland forest and edge preferred, but also uses second growth, partly cleared areas, coconut plantations, parks and gardens up to 600 m, although mountain overflights may be much higher, and found at 900 m, Guadalcanal and San Cristobal, 1760 m in S New Ireland.
Food and Feeding. Small seedy fruit recorded in stomachs. According to local reports, Bougainville, both wild and cultivated (unripe) bananas *Musa* are staple.
Breeding. Oct, but with female feeding juvenile in Aug. Nest in hole in dead limb of cultivated breadfruit (*Artocarpus altilis*); use of dead stump also recorded.

Greensmith (1975), Hadden (1981), LeCroy & Peckover (1983), Mayr (1945b), Orenstein (1976), Schodde (1977), Virtue (1947), Webb (1992, 1997).

Movements. No information. High flights between localities may occur on a daily basis.
Status and Conservation. Not globally threatened. CITES II. A BirdLife “restricted-range” species. Apparently now very uncommon, New Britain and New Georgia, although common in the former in 1920’s. Locally common on Santa Isabel and Guadalcanal, and uncommon to moderately abundant, Bougainville. Highly secretive behaviour may mask true abundance.
Bibliography. Beehler (1978a), Blaber (1990), Bradley & Wolff (1956), Buckingham *et al.* (1995), Cain & Galbraith (1956), Coates (1985), Donaghho (1950), Eastwood (1995c), Gilliard & LeCroy (1967a),

PLATE 39

inches 6
cm 15

Genus *PRIONITURUS* Wagler, 1832

115. Montane Racquet-tail

Prioniturus montanus

French: Palette momot **German:** Motmotpapagei **Spanish:** Lorito-momoto Montano
Other common names: Mountain/Crimson-spotted/Luzon/Red-crowned Racquet-tail/Racquet-tailed Parrot

Taxonomy. *Prioniturus montanus* Ogilvie-Grant, 1895, mountains of Lepanto, Luzon. Forms a superspecies with *P. waterstradti*, *P. platenae* and debatably *P. verticalis*. Frequently united with *P. waterstradti*; less commonly with *P. verticalis* too. Monotypic.
Distribution. Luzon (N Philippines).

Descriptive notes. 30 cm; 102-142 g. Bill pale greyish; dull green on upperparts, yellowish green below; forehead and face blue, shading to green on lower cheeks and rear ear-coverts; mid-crown red; tail spatules blackish. Female has entire head green but for blue tinges. Immature like female without spatules.
Habitat. Primary montane forest above 700 m.
Food and Feeding. Fruits of a fine-leaved tree growing low inside forest appears to be the only record.
Breeding. Aug-Sept; but juvenile collected Jul. Nest recorded 5-6 m up in tall oak stub.
Movements. Partial displacements from the

highlands may occur with some regularity.
Status and Conservation. **VULNERABLE.** CITES II. A BirdLife "restricted-range" species. Although common in both the Cordillera Central and the Sierra Madre, the combination of habitat loss, hunting and trapping for the cagebird trade is predicted to inflict serious damage on populations.
Bibliography. Collar *et al.* (1994), Danielsen *et al.* (1994), Delacour & Mayr (1946), Dickinson *et al.* (1991), DuPont (1971), Inskipp *et al.* (1996), McGregor (1909-1910), Morioka & Sakane (1979), Poulsen (1995), Rabor (1955), Salomonsen (1953), Sargeant (1992).

116. Mindanao Racquet-tail

Prioniturus waterstradti

French: Palette de Mindanao **Spanish:** Lorito-momoto de Mindanao
German: Mindanao-Spatelschwanzpapagei

Taxonomy. *Prioniturus waterstradti* Rothschild, 1904, Mount Apo, 3000 feet (c. 1000 m), Mindanao. Forms superspecies with *P. montanus*, *P. platenae* and debatably *P. verticalis*. Often considered conspecific with *P. montanus*. Monotypic.
Distribution. Mountains of Mindanao (SE Philippines).

Descriptive notes. 27 cm. Similar to *P. montanus* but with less extensive blue on face and no red patch on crown, brown tinge to mantle and back. Female similar. Immature lacks spatules.
Habitat. Dense montane forest, ridgetop forest, and (at higher elevations) stunted mossy forest; 820-2700 m, and generally above 1000 m.
Food and Feeding. No information.
Breeding. No information.
Movements. Considerable vertical movements reputedly take place each day, but no other kind appears to have been reported.

Status and Conservation. **VULNERABLE.** CITES II. A BirdLife "restricted-range" species. The species was abundant in the first half of this century, but had become local and uncommon, apparently occurring at lower density than some of its congeners, by the early 1990's. However, in Mt Katanglad National Park it remains fairly common on Mts Imbayao, Nangkabulos and Dulang-dulang.
Bibliography. Collar *et al.* (1994), Delacour & Mayr (1946), Dickinson *et al.* (1991), DuPont (1971), Hachisuka (1930), Heaney *et al.* (1993), Inskipp *et al.* (1996), McGregor (1909-1910), Mearns (1909), Meyer de Schauensee & DuPont (1962), Rand & Rabor (1960), Ripley & Rabor (1961), Salomonsen (1953), Sargeant (1992), Wheatley (1996).

117. Blue-headed Racquet-tail

Prioniturus platenae

French: Palette de Palawan **Spanish:** Lorito-momoto de Palawan
German: Palawan-Spatelschwanzpapagei
Other common names: Palawan Racquet-tail

Taxonomy. *Prioniturus platenae* A. W. H. Blasius, 1888, Palawan. Forms a superspecies with *P. montanus*, *P. waterstradti* and debatably *P. verticalis*. Previously treated as a race of *P. discurus*. Monotypic.
Distribution. Palawan and associated islands (SW Philippines).
Descriptive notes. 27 cm. Pale greyish yellow bill; entire head and nape light blue extending onto breast, becoming greener on lower breast and belly and yellow on vent; upperparts dull green;

spatules dark green. Female has blue confined to crown and sides of head. Immature similar, with no spatules.
Habitat. Lowland forest and edges, and adjacent cultivations, apparently in the lowlands to around 300 m.
Food and Feeding. No observations; nuts in stomachs of specimens.
Breeding. Birds labelled juvenile have been collected in Jan (two) and Aug, and one labelled immature in May.
Movements. No information.
Status and Conservation. **VULNERABLE.** CITES II. The paucity of recent records of the

Blue-headed Racquet-tail indicates that it is now generally uncommon and declining, although it is regularly recorded in St Paul's Subterranean National Park.
Bibliography. Baud (1978), Collar *et al.* (1994), Dickinson *et al.* (1991), DuPont (1971), Inskipp *et al.* (1996), Lowe (1916), McGregor (1909-1910), Salomonsen (1953), Sargeant (1992), Wheatley (1996).

118. Green Racquet-tail

Prioniturus luconensis

French: Palette verte **German:** Luzon-Spatelschwanzpapagei **Spanish:** Lorito-momoto de Luzón
Other common names: Green-headed/Green-crowned Racquet-tail/Racquet-tailed Parrot

Taxonomy. *Prioniturus luconensis* Steere, 1890, Marinduque and Luzon. Forms a superspecies with *P. discurus*, probably *P. flavicans* and debatably *P. verticalis*. Monotypic.
Distribution. Luzon and Marinduque, N Philippines.

Descriptive notes. 29 cm. Bill pale greyish; yellowish green on head and underparts, slightly darker on wings and tail, with spatules blackish and lateral feathers above dark blue tipped black. Female less yellowish. Immature lacks spatules.
Habitat. Canopy of primary forest and edge, occasionally foraging out in open cultivated areas, in lowlands and foothills, e.g. in Sierra Madre at 300-700 m. Recorded recently from selectively logged and degraded forest, but ability to persist in such habitat unclear.
Food and Feeding. Fruit, particularly bananas, flowers and seeds of growing corn, and rice.

Breeding. Young obtained in May.
Movements. No information.
Status and Conservation. **ENDANGERED.** CITES II. A BirdLife "restricted-range" species. Combination of habitat loss and trade has rendered this species very uncommon and local, with a single good population protected, at Subic Bay Naval Forest Reserve; it is very rare in Quezon National Park.
Bibliography. Collar & Andrew (1988), Collar *et al.* (1994), Danielsen *et al.* (1994), Delacour & Mayr (1946), Dickinson *et al.* (1991), DuPont (1971), Gilliard (1950b), Gonzales & Rees (1988), Hachisuka (1934), Inskipp *et al.* (1996), McGregor (1909-1910), Poulsen (1995), Salomonsen (1953), Sargeant (1992), Wheatley (1996).

119. Blue-crowned Racquet-tail

Prioniturus discurus

French: Palette à couronne bleue **Spanish:** Lorito-momoto Coroniazul
German: Philippinen-Spatelschwanzpapagei
Other common names: Blue-headed Racquet-tail(!)

Taxonomy. *Psittacus discurus* Vieillot, 1822, Mindanao. Forms a superspecies with *P. luconensis*, probably *P. flavicans* and debatably *P. verticalis*. Sometimes considered conspecific with *P. flavicans*, and previously with *P. platenae*. Proposed race *nesophilus* of Catanduanes I is synonym of *whiteheadi*. Three subspecies recognized.
Subspecies and Distribution.
P. d. whiteheadi Salomonsen, 1953 - Luzon S to Bohol, N & CE Philippines.
P. d. mindorensis Steere, 1890 - Mindoro, NC Philippines.
P. d. discurus (Vieillot, 1822) - Mindanao, Basilan, Sulu and Olutanga, SE & SC Philippines.

Descriptive notes. 27 cm; 86-176 g. Crown to hindneck pale blue; rest of face to chin and nape apple green; underparts yellowish green; back and wings darker green; undersides of flight-feathers greenish blue; tail dark greenish, spatules blackish, lateral feathers blue edged green and tipped black. Female has shorter spatules. Immature duller, with reduced blue on crown, lacks spatules. Race *whiteheadi* has less extensive blue on crown; *mindorensis* has green forehead, deeper blue on rest of crown.
Habitat. Primary and secondary forest up to 1750 m; also mangroves, orchards and banana plantations.
Food and Feeding. Poorly documented; apparently fond of bananas, inflicting damage on unripe crops adjacent to forest. Repeated presence in *Ficus*, Sibuyan, suggests use as food.
Breeding. Apr-May; pair "billing" in Feb, Mindanao. Nesting reputedly colonial in tall dead trees. Eggs 3.
Movements. Birds arrived on Calicoan, off S Samar, after breeding, becoming commoner into Sept-Oct; no other information suggests migratory behaviour.

Status and Conservation. Not globally threatened. CITES II. Generally common even in degraded habitat on largely deforested islands such as Mindoro and Negros; however, not common on Sibuyan; regularly recorded at PICOP logging concession near Bislig, Mindanao.

Bibliography. Brooks *et al.* (1992), Delacour & Mayr (1946), Dickinson *et al.* (1991), DuPont (1971, 1972a), Dutton *et al.* (1992), Evans, Dutton & Brooks (1993), Gonzales (1983), Goodman *et al.* (1995), Inskipp *et al.* (1996), McGregor (1909-1910), Ogilvie-Grant (1906), Parkes (1971a), Potter (1953), Rabor (1977), Rand & Rabor (1960), Ripley & Rabor (1958), Salomonsen (1953), Sargeant (1992).

120. Sulu Racquet-tail

Prioniturus verticalis

French: Palette des Sulu

Spanish: Lorito-momoto de las Sulu

German: Sulu-Spatelschwanzpapagei

Other common names: Blue-winged Racquet-tail

Taxonomy. *Prioniturus verticalis* Sharpe, 1893. Tawi Tawi, Sibutu and Bongao. May belong in superspecies with *P. luconensis*, *P. discurus* and *P. flavicans*, or alternatively with *P. montanus*, *P. waterstradti* and *P. platenae*. Sometimes still treated as conspecific with *P. montanus*. Monotypic.

Distribution. Sulu Archipelago, S Philippines.

Descriptive notes. 30 cm. Similar to *P. montanus* but forehead, sides of head and nape green. Female like female *montanus* but with no blue on face. Immature lacks spatules.

Habitat. Primary lowland forest bird, including mangroves, forest edge adjacent to cleared areas.

Food and Feeding. No precise information.

Breeding. Sept-Jan. Nest recorded in a large broken-off palm tree in a grove of palms close to forest.

Movements. No information.

Status and Conservation. ENDANGERED.

CITES II. A BirdLife "restricted-range" species. Only small numbers observed in Tawitawi in 1991, just six were seen in Aug 1994, and a survey in Jan 1995 missed the species entirely. There is no report from Bongao, Tumindao or Manuk Manka for at least 90 years. The species's last habitat on Tawitawi is about to disappear, and habitat loss on some of the other islands in the Sulus indicates the gravity of the situation. This problem is exacerbated by the human use of large birds, including racquet-tails, for target practice, many men on Tawitawi being armed with high-powered rifles.

Bibliography. Collar *et al.* (1994), Delacour & Mayr (1946), Dickinson *et al.* (1991), DuPont (1971), DuPont & Rabor (1973a), Dutton *et al.* (1992), Inskipp *et al.* (1996), Lambert (1993b), McGregor (1909-1910), Robson (1992), Salomonsen (1953), Sargeant (1992), Wheatley (1996).

121. Yellowish-breasted Racquet-tail

Prioniturus flavicans

French: Palette de Cassin

Spanish: Lorito-momoto Amarillento

German: Flaggenschwanzpapagei

Other common names: Yellow-breasted/Red-spotted/Crimson-spotted Racquet-tail

Taxonomy. *Prioniturus flavicans* Cassin, 1853. Sulawesi.

Probably forms a superspecies with *P. luconensis*, *P. discurus* and debatably *P. verticalis*. Sometimes considered conspecific with *P. discurus*. Monotypic.

Distribution. N half of Sulawesi and associated islands.

Descriptive notes. 37 cm. Bill pale bluish grey; forehead and face green; crown to hindneck rich blue with red patch in mid-crown; breast, sides of neck, nape and mantle dull olive-yellow shading to yellowish green on underparts and to dull green on back and wings and tail, with blackish spatules. Female has blue reduced or even absent, and no red on crown. Immature like female but even less blue, no spatules.

Habitat. Primary lowland forest to around 1000 m, occasionally in stands of trees at forest margins.

Food and Feeding. No information.

Breeding. No information.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. Not as common as *P. platurus* and usually only seen singly or in pairs, but still fairly numerous overall; especially common in Dumoga-Bone National Park. Nevertheless, extensive forest loss in lowland areas within the range of this bird has raised concerns for its long-term prospects.

Bibliography. Andrew (1992), Coates & Bishop (1997), Collar *et al.* (1994), Holmes & Philipps (1996), Inskipp *et al.* (1996), Rozendaal & Dekker (1989), Stresemann (1940), Sujatnika *et al.* (1995), Watling (1983), Wheatley (1996), White & Bruce (1986).

122. Golden-mantled Racquet-tail

Prioniturus platurus

French: Palette à manteau d'or

Spanish: Lorito-momoto Dorsidorado

German: Goldmantelpapagei

Other common names: Gold-backed Racquet-tail

Taxonomy. *Psittacus platurus* Vieillot, 1818. New Caledonia; error = Sulawesi.

Forms a superspecies with *P. mada*. Three subspecies recognized.

Subspecies and Distribution.

P. p. talautensis Hartert, 1898 - Talaud Is.

P. p. platurus (Vieillot, 1818) - Sulawesi and associated islands.

P. p. sinerubris Forshaw, 1971 - Taliabu in Sula Is.

Descriptive notes. 28 cm. Bill pale greyish; green on head with red spot on hindcrown bordered behind by larger lilac patch; dull orange lateral stripe across mantle; rest of mantle, back and wing-coverts dull grey; central tail feathers green above, with blackish spatules, lateral feathers green with blue edging and black tips; yellowish green on undersides. Female green. Immature like female with no spatules. Race *talautensis* darker with less grey upperparts: *sinerubris* also less grey, smaller, without red spot on crown.

Habitat. Lowland rain forest up to elfin moss forest at 3000 m; perhaps most numerous at 1800-2000 m. Also at forest edge and even at mango trees in villages.

Food and Feeding. Small fruits and seeds taken in interior of forest from substage to lower canopy; fond of cultivated mangoes and reported to visit ripening corn at night.

Breeding. Oct. Nest in hole in limb or tree.

Movements. No regular movements recorded, but birds move daily over large distances in search of food.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Common, occurring in small parties throughout Sulawesi. May have declined mid-century on Muna and Buton islands owing to trapping.

Bibliography. Andrew (1992), van Bemmell & Voous (1951), Bishop (1992), Coates & Bishop (1997), Eck (1976, 1977), Forshaw (1971b), Fraser & Henson (1996), Holmes & Philipps (1996), Rozendaal & Dekker (1989), Seth-Smith (1903), Stresemann (1940), Watling (1983), Wheatley (1996), White & Bruce (1986).

123. Buru Racquet-tail

Prioniturus mada

French: Palette de Buru

German: Madapapagei

Spanish: Lorito-momoto de Buru

Taxonomy. *Prioniturus mada* Hartert, 1900, Mount Mada, 3000 feet (c. 1000 m), Buru.

Forms a superspecies with *P. platurus*. Monotypic.

Distribution. Buru, S Moluccas.

Descriptive notes. 32 cm. Bill bluish grey; face, forehead and ear-coverts rich green; mid-crown to nape, mantle and shoulders purplish, shading on back and wings to olive-green, and in turn to oil green on flight-feathers, rump and tail, spatules dark blackish blue; leading edge of wing blue. Female lacks purple except as stain on hindneck and mantle. Immature like female but lacks spatules.

Habitat. Rain forest, ranging from sea-level up to at least 1750 m; reports of altitudinal preferences now considered to be unsubstantiated.

Food and Feeding. No information.

Breeding. Dec-Feb. Nest in hollow limb or hole in tree. Five young in one nest included one large, fully feathered bird and one small, entirely down-covered hatchling.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. The mountains of Buru remain well forested, there is apparently no trade in this species, and it was common and widespread, including in selectively logged forest, with flocks of 4-10 regularly seen, late 1989.

Bibliography. Andrew (1992), Arndt (1992b), Coates & Bishop (1997), Collar & Andrew (1988), Collar *et al.* (1994), Jepson (1993), Marsden *et al.* (1997), Robson (1990a), Siebers (1930), Stresemann (1913b), Sujatnika *et al.* (1995), Wheatley (1996), White & Bruce (1986).

Genus *TANYGNATHUS* Wagler, 1832

124. Great-billed Parrot

Tanygnathus megalorynchos

French: Perruche à bec de sang **German:** Schwarzschnulterpapagei **Spanish:** Loro Picogordo

Other common names: Large-billed/Moluccan/Island Parrot

Taxonomy. *Psittacus megalorynchos* Boddaert, 1783. New Guinea (= West Papuan Islands?). May form a superspecies with *T. lucionensis*. Nominat race shows much variation, some apparently clinal; now considered to include proposed races *viridipennis*, *djampeae*, *floris*, *obiensis*, *bachianensis*, *fuliginosus* and *insularum*. Five subspecies currently recognized.

Subspecies and Distribution.

T. m. megalorynchos (Boddaert, 1783) - Talaud, Sangihe and islands off N, E & S Sulawesi S to Flores (Lesser Sundas) and E through N & C Moluccas to W Papuan Is and other islands off W Irian Jaya; present also on Balut and Sarangani off Mindanao (SE Philippines), where possibly introduced; specimens from N Sulawesi may have been wanderers or introductions, while sight records remain open to question.

T. m. affinis Wallace, 1863 - S Moluccas.

T. m. sumbensis A. B. Meyer, 1881 - Sumba.

T. m. hellmayri Mayr, 1944 - W Timor and Semau I.

T. m. subaffinis P. L. Slater, 1883 - Tanimbar Is.

Descriptive notes. 33-43 cm. Enormous bill red; head, nape and mantle bright green, shading to pale blue on back and rump and to yellowish on underparts, with yellow flanks, underwing-coverts

and across undersides of flight-feathers; scapulars and lesser wing-coverts black, median wing-coverts black edged yellow; greater wing-coverts and secondaries green edged yellow; primaries blue; tail above green tipped yellow, below yellowish. Immature lacks black at shoulder. Nominate apparently has two types of variation, which has led to establishment of several supererogatory subspecies: in one, margins of flight-feathers are green instead of blue, (hence "*viridipennis*" of Tukangbesi, Madu and Kalaotoa Is, and "*djampeae*" of Tanahjampea and Kalao, all S of Sulawesi); in other, undersides somewhat greener (again in "*djampeae*" and in "*floris*" of Flores). Race *affinis* has bluish tinge to head, green scapulars, lesser wing-coverts greenish blue; *subaffinis* like *affinis* with rump very pale blue, underwing-coverts bluish; *hellmayri* like *affinis* but with yellowish green head, greener wing covert edges; *sumbensis* like nominate but head darker green, underparts greener, rump darker blue.

Habitat. Primary and secondary lowland evergreen forest, preferably with a rather open structure and with a scattering of large deciduous trees, but also *Casuarina* forest, mangroves, plantation edge and garden areas in lowlands. A small-island specialist, being confined on larger islands to coastal areas and adjacent foothills. Birds may go to roost in higher parts of islands, returning early each morning to lowlands.

Food and Feeding. The fruit of *Sonneratia alba* reportedly much favoured, also *Canarium vulgare* and casuarinas; a green lemon-sized fruit reportedly important, the birds travelling from island to island in search of it. Apparently visits corn crops.

Breeding. Nest-sites apparently occupied, Aug-Sept; Aug-Sept on Sumba. Nest in hole in very tall deciduous tree.

Movements. Apparently often travels between adjacent small islands, but this is presumably generally only a very local phenomenon.

Status and Conservation. Not globally threatened. CITES II. Seram may hold 100,000 birds, and the species is still in healthy numbers on Tanahjampea, Flores Sea; Buru has been reckoned to hold c. 7500 birds, but probable numbers now considered much higher. On Ambon (S Moluccas), found to be common in forested hills behind Hila on N coast of Hita Peninsula, in 1995. However, only 1700 birds estimated to remain on Sumba, where the race *sumbensis* is endangered by habitat loss, and on Flores species has suffered a marked decline from the cagebird trade. The species was abundant on Balut and Sarangani in 1906 and was still common on the latter in 1978. Reported international trade, 1985-1990, averaged 1206 birds per year, but the EC prohibited importations in Sept 1991.

Bibliography. Andrew (1992), Anon. (1993), Beehler *et al.* (1986), Bowler & Taylor (1989), Butchart *et al.* (1996), Coates & Bishop (1997), De Dios & Sweeney (1994b), Dickinson *et al.* (1991), Dutton (1995), Hachisuka (1935), Harrison & Holyoak (1970), Jepson (1993), Jones, Juhaeni *et al.* (1994), Jones, Linsley & Marsden (1995), Lever (1987), Low (1989a), MacKinnon (1988), MacKinnon & Phillips (1993), Marsden (1995), Mayr (1944b), Mees (1965, 1982b), O'Connor (1994), Rand & Gilliard (1967), Siebers (1930), Smiet (1985), Tabaranza & Alconcel (1979), Thompson (1993), White & Bruce (1986).

125. Blue-naped Parrot

Tanygnathus lucionensis

French: Perruche de Luçon **German:** Blaunackenpapagei **Spanish:** Loro Nuquiazul
Other common names: Blue-crowned Parrot

Taxonomy. *Psittacus lucionensis* Linnaeus, 1766, Luzon.

May form a superspecies with *T. megalorhynchus*. Four subspecies recognized.

Subspecies and Distribution.

T. l. lucionensis (Linnaeus, 1766) - Luzon and Mindoro, N Philippines.

T. l. hybridus Salomonsen, 1952 - Polillo, N Philippines.

T. l. salvadorii Ogilvie-Grant, 1896 - Philippines (except N) and Malaysian islands off NE Borneo.

T. l. talautensis A. B. Meyer & Wigglesworth, 1895 - Talaud Is (S of Philippines).

Feral population (presumably race *salvadorii*) found around Kota Kinabalu, Sabah.

Descriptive notes. 31 cm; 148-231 g. Green, brighter on head and rump; bill red; mid-crown to nape pale blue; back suffused blue; bend of wing black, lesser wing-coverts black with broad orange-buff edging; other wing feathers blue and green; tail dusky yellow below. Immature duller, with little blue on head. Race *hybridus* has reduced blue on head and back, less black in wing; *salvadorii* has all-green back; *talautensis* has all-green back but blue of head extending onto cheeks.

Habitat. Lowland forest up to 1000 m, secondary forest and scattered trees within agricultural lands close to forest; also mangroves,

coconut groves and banana patches. Although present on large islands, this bird appears to be a small-island specialist adapted to survival in relatively confined wooded areas.

Food and Feeding. Fruits and seeds of forest trees, palm fruit, young coconuts, bananas and papaya.

Breeding. Apr-Jun. Nest in natural cavity or in deserted hole of large woodpecker, often in a clearing.

Movements. No information. Populations confined to small islands must be highly sedentary, but regular dispersal from such sites also seems likely.

Status and Conservation. ENDANGERED. CITES II. Possibly now extinct on Negros and Siquijor, and very rare on Mindoro, Luzon and other islands, owing to combination of habitat loss and high levels of illegal trade for both domestic and international markets; it is clearly uncommon on Sibuyan. However, the number of small islands on which it survives is not known and may in fact be very considerable. It was very common on larger islands in the Sulu Archipelago in 1971. It survives on Palawan albeit under great trapping pressure, and remains common in Talaud Is, although judged uncommon on Salebabu in 1985, but regular there and on Karakelong in 1995. It occurs in some national parks in Philippines, e.g. Bataan National Park, Quezon National Park and Minalungaw National Park, Luzon, and fairly common in St Paul's Subterranean National Park, Palawan.

Bibliography. Andrew (1992), Brooks *et al.* (1992), Coates & Bishop (1997), Collar *et al.* (1994), De Dios & Sweeney (1994a), Delacour & Mayr (1946), Desborough (1991), Dickinson *et al.* (1991), DuPont (1971), Dutton *et al.* (1992),

Evans, Dutton & Brooks (1993), Evans, Magsalay *et al.* (1993), Goodman *et al.* (1995), Harrison & Holyoak (1970), Jenkins (1976), Lambert (1993b), Lever (1987), Low (1989a), Luczak (1980), MacKinnon & Phillips (1993), Parkes (1971a), Rabor (1976, 1977), Rand & Rabor (1960), Riley (1997), Salomonsen (1953), Sargeant (1992), Smith (1984), Smythies (1981), Thompson, D.R. (1993), Thompson, M.C. (1966), White & Bruce (1986).

126. Blue-backed Parrot

Tanygnathus sumatranus

French: Perruche de Müller **German:** Everettpapagei **Spanish:** Loro de Müller
Other common names: Müller's/Azure-rumped Parrot

Taxonomy. *Psittacus Sumatranus* Raffles, 1822, Butung.

Proposed race *mulleri* is synonym of nominate, and indeed species formerly listed as *T. mulleri*; birds of Banggai have been awarded race *incognitus*, based on supposedly different iris colour, but data come from unreliable labels. "*T. heterurus*" (Rufous-tailed/Salvadori's Parrot) probably described from an aberrant specimen of present species. Six subspecies recognized.

Subspecies and Distribution.

T. s. duponti Parkes, 1971 - Luzon (N Philippines).

T. s. freeri McGregor, 1910 - Polillo (N Philippines).

T. s. everetti Tweeddale, 1877 - Visayan Is and Mindanao (CE & SE Philippines).

T. s. burbidgii Sharpe, 1879 - Sulu Is (SC Philippines).

T. s. sangirensis A. B. Meyer & Wigglesworth, 1894 - Sangihe and Talaud Is.

T. s. sumatranus (Raffles, 1822) - Sulawesi and adjacent islands E to Sula and Banggai Is, Muna and Butung.

Descriptive notes. 32 cm; 173-334 g. Large bill red; head bright green, becoming more yellowish on mantle and underparts, and darker on wings and tail; lower back and rump rich blue; lesser wing-coverts edged blue, other wing-coverts lightly edged yellowish; tail yellowish below. Female has bill pale horn. Immature like female. Race *sangirensis* bluer on bend of wing; *burbidgii* darker, with more yellowish head and deeper blue rump; *everetti* with yellowish green collar; *duponti* like *everetti* with paler blue rump; *freeri* larger, more yellowish, with mantle edged blue.

Habitat. Lowland and lower montane forest, lowland and deeper blue swamp forest, savanna, being commonest up to 500 m. Where sympatric with *T. lucionensis* on Sulus, more a bird of island interiors.

Food and Feeding. Often found in *Leptospermum* and *Ficus* trees, so their fruits presumably taken. Attacks and can cause serious damage to ripening corn. Often active at night, making damage prevention difficult.

Breeding. Apr on Samar (CE Philippines); otherwise known from Oct-Nov. One nest recorded in hollow of tree 30 m above ground, with two young; another was 50 m up.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Common on Sulawesi, and in 1971 very common on the larger islands of the Sulu Archipelago. In 1978 it was found in smaller numbers than *T. lucionensis* in Talaud Is, and in mid-century was thought possibly over-trapped on Muna and Buton. In 1980's a certain amount of trade took place of birds named *T. heterurus* (name probably based on aberrant specimen of present species) which probably actually involved present species.

Bibliography. Andrew (1992), Anon. (1993), van Bemmelen & Voous (1951), Bishop (1992), Brooks *et al.* (1992), Coates & Bishop (1997), Coomans de Ruiter (1951), Delacour & Mayr (1946), Dickinson *et al.* (1991), DuPont (1971), Fraser & Henson (1996), Harrison & Holyoak (1970), Inskipp *et al.* (1996), Low (1989a), McGregor (1909-1910), Parkes (1971b, 1973), Rand & Rabor (1960), Rozendaal & Dekker (1989), Salomonsen (1952), Sargeant (1992), Stresemann (1938, 1940), Thompson (1993), Watling (1983), White & Bruce (1986).

127. Black-lored Parrot

Tanygnathus gramineus

French: Perruche de Buru **German:** Burupapagei **Spanish:** Loro de Buru
Other common names: Buru Parrot

Taxonomy. *Psittacus gramineus* J. F. Gmelin, 1788, Ambon; error = Buru.

Monotypic.

Distribution. Buru, S Moluccas.

Descriptive notes. 40 cm. Generally dull green throughout, slightly brighter on hindneck; bill red; crown and upper cheeks lightly washed bluish grey bisected by a black line through lores and shading to olive-yellow of throat and foreneck; primary coverts and primaries dull blue and edged green on outer vanes, blackish on inner; tail tipped greenish yellow, dull yellow below. Female has pinkish grey bill. Immature undescribed.

Habitat. Montane forest above 600-700 m. Birds, assumed to be this species were heard nightly arriving downslope in trees at 1100 m, just after full darkness.

Food and Feeding. No detailed information, but may be largely nocturnal.

Breeding. No information.

Movements. Apparently resident.

Status and Conservation. VULNERABLE. CITES II. A BirdLife "restricted-range" species. Very poorly known, owing to at least partially nocturnal habits, but upland forest on Buru now judged to be relatively secure compared to lowland areas, so the species might warrant downlisting from threatened status, particularly as it appears still to be fairly common within its very small range.

Bibliography. Andrew (1992), Anon. (1996b, 1996c), Coates & Bishop (1997), Collar *et al.* (1994), Jepson (1993), Low (1989a, 1994b), Poulsen & Purmiasa (1996), Rudyanto (1996), Siebers (1930), Smiet (1985), Sujatnika & Jepson (1995), Sujatnika *et al.* (1995), Thompson (1993), Wheatley (1996), White & Bruce (1986).

Genus *ECLECTUS* Wagler, 1832

128. Eclectus Parrot

Eclectus roratus

French: Grand Éclectus **German:** Edelpapagei **Spanish:** Loro Ecléctico
Other common names: Red-sided (Eclectus) Parrot, Kalanga

Taxonomy. *Psittacus roratus* P. L. S. Müller, 1776, Ambon. Genus name formerly given as *Lorius* Boddaert, 1783, although original spelling, was “*Larius*”; this name (either spelling) officially suppressed in 1970, giving way to *Eclectus* for present species, and leaving genus name *Lorius* Vigors, 1825, available for “*Domicella*” lories. Race *polychloros* formerly known as *pectoralis*, but latter name now considered a synonym of nominate. Proposed race “*westermanni*” is known only from four aviary specimens of unknown provenance dating from before 1850. Nine subspecies recognized.

Subspecies and Distribution.

E. r. vosmaeri (Rothschild, 1922) - N & C Moluccas.
E. r. roratus (P. L. S. Müller, 1776) - S Moluccas.
E. r. cornelia Bonaparte, 1850 - Sumba (Lesser Sundas).
E. r. riedeli A. B. Meyer, 1882 - Tanimbar Is.
E. r. aruensis G. R. Gray, 1858 - Aru Is.
E. r. biaki (Hartert, 1932) - Biak I.
E. r. polychloros (Scopoli, 1786) - New Guinea and adjacent islands and archipelagos.
E. r. solomonensis Rothschild & Hartert, 1901 - Admiralty Is, Bismarck Archipelago and Solomon Is.
E. r. macgillivrayi Mathews, 1913 - extreme N Queensland.
Introduced (possibly *solomonensis*) to Palau.

Descriptive notes. 35-42 cm; 355-615 g. Male green; upper mandible yellowish red, lower black; flanks and underwing-coverts red; leading edge of wing blue; primaries with deep blue; tail above with increasing blue suffusion laterally, below brownish black, tipped yellowish white both sides. Female red, darker on back and wings; bill black; lower breast to abdomen, underwing-coverts and band across mantle purplish blue; leading edge of wing blue; primaries with deep blue; tail above tipped orange-yellow, below dark red becoming orange-pink distally. Immature resembles adult of respective sex; bill greyer. Race *vosmaeri* male has yellow tinge to head, female yellow undertail-coverts; *cornelia* large, female almost entirely red; *riedeli* small, female almost entirely red, tail with yellow; *polychloros* large, male with yellow tail-tips, female breast and abdomen blue with little purple, undertail-coverts red; remaining subspecies like *polychloros* but *biaki* smaller, *aruensis* with tail more broadly tipped yellow in male, brighter blue in female, *macgillivrayi* larger; *solomonensis* smaller with smaller bill, males more yellowish.

Habitat. Occupies canopy of all wooded habitats from coast to mid-montane areas, including mangroves, nypa forest, freshwater swamp- and dryland forest, coastal scrub, denser savanna woodland, parkland, plantations, secondary growth and garden areas, but commonest in primary lowland forest. On Sumba lowland secondary forest may be preferred. Above 1000 m becomes much rarer, but encountered up to 1900 m; in Solomons transect evidence suggests it may be a lowland species.

Food and Feeding. Fruits, seeds, nuts, leaf-buds, blossoms all taken, with *Parinarium* and *Pandanus* much targeted; in Solomons fig-like fruit found in guts. Said to raid gardens for fruit, New Georgia and Obi, and witnessed doing so, Bougainville and Guadalcanal.

Breeding. Generally Aug-Sept, possibly Jan, and very likely at any time of year; Nov on Buru; Apr-Aug in Solomons. Nest in hole in high tree, generally in a clearing or at forest edge; on Sumba and in Australia deciduous trees greatly preferred, in former case with as many as 4 active nests in one tree, in latter case often near water. Up to 8 birds of both sexes may attend nests, though not always more than a pair. Eggs 2; in captivity, incubation recorded at 26 days, nestling period 12 weeks.

Movements. Local movements observed may only be daily feeding flights.

Status and Conservation. Not globally threatened. CITES II. Common, Halmahera. Moderately common but declining with elevation, Seram. Although still fairly common on Bacan, now rare on Obi, having been so common 40 years ago that it was a major crop pest; the decline is due to overtrapping, which suggests the species is unable to recover from heavy exploitation. Uncommon, Buru. Population on Sumba perhaps only 1900 birds and in great danger from habitat loss and moderate trapping pressure, which targets red females. Uncommon on Kai Is. Generally common and in places abundant on New Guinea mainland (although in one study only 10 birds/km² estimated), W Papuan Is, Bismarck Archipelago, Bougainville, New Georgia and other Solomon Is; uncommon on Guadalcanal, perhaps as a result of lack of sufficiently large trees for nesting. Increasing habit of raiding gardens for cultivated fruit in Solomons apparently correlated with recent large-scale clearance of lowland forest in many areas. In N Australia a steep decline appears to have occurred in past 30 years, attributable to illegal trapping and perhaps to inappropriate fire regimes. Males commonly seen more than females and often judged greatly to outnumber them, but on Bismarck the opposite is true; however, there is possibly some seasonal or other bias in such observations, and it may simply be that males have different foraging strategies involving daily displacements, while females remain tied to primary forest and fly much less (in captivity females spend much time in nest cavity even when not breeding).

(1993), White & Bruce (1986).

Genus *ALISTERUS* Mathews, 1911

129. Australian King-parrot

Alisterus scapularis

French: Perruche royale **German:** Königssittich **Spanish:** Papagayo Australiano
Other common names: King Parrot

Taxonomy. *Psittacus scapularis* Lichtenstein, 1818, New South Wales. Genus has occasionally been lumped with *Aprosmictus*. Two subspecies recognized.

Subspecies and Distribution.

A. s. minor Mathews, 1911 - NE Queensland.
A. s. scapularis (Lichtenstein, 1818) - NC Queensland S to S Victoria.

Descriptive notes. 42-43 cm; 209-275 g. Very similar to *A. amboinensis* but larger, with mantle and upper back oil green, inner series of upperwing-coverts pale green, underwing-coverts oil green tinged blue; undertail-coverts broadly scalloped green; tail greenish black above, greyish black below. Female like female *A. chloropterus* but with undertail-coverts scalloped green, occasional hint of pale scapulars, bill dark brownish. Immature like female but bill paler. Race *minor* smaller.

Habitat. Rain forest, *Eucalyptus* woodland, dense riparian scrub and occasionally adjacent savanna from sea-level to 1600 m, utilizing

these more open habitats outside breeding season, when also visits urban parklands and farm areas.

Food and Feeding. Seeds of eucalypts, acacias and *Angophora* particularly favoured, also of *Baloghia lucida*, plus fruits and berries of *Geijera parviflora*, *Solanum nigrum*, *S. auriculatum* and *Phytolacca octandra*, mistletoes, grass seeds, nectar, blossoms and buds. Birds raid orchards, maize and sorghum crops, sometimes taking spilt grain from farmyards, and come into gardens to feed on cultivated *Pyraacantha*, *Cotoneaster* and *Crataegus* berries plus *Quercus* acorns.

Breeding. Sept-Jan. Nest in hollow limb or in deep hole in tall forest tree. Eggs 3-6, usually 5; incubation, by female only, lasts c. 20 days; nestling period c. 5 weeks.

Movements. Notably in S of range flocks descend from mountains in late autumn and remain in lowlands until Sept. Year-round lowland birds appear to be resident once adult, but immatures show undefined movements, forming flocks of up to 30 in autumn. Birds of all ages may congregate at concentrated food resources such as fruiting trees and ripening maize.

Status and Conservation. Not globally threatened. CITES II. Generally common but lost from cleared and afforested areas.

Bibliography. Blakers *et al.* (1984), Chisholm (1934), Cooper & Frith (1994), Courtney (1997a), Emison *et al.* (1987), Favalaro (1931), Forshaw (1981b), Lepschi & Courtney (1992), Ley (1993), Lindsey, T.R. (1992), Macdonald (1988), Pizzey & Doyle (1980), Rattray (1993), Rose (1997b), Schodde & Tidemann (1986), Simpson & Day (1996), Tronson & Tronson (1987), Vriends (1979), Wood, K.A. (1992), Woodall (1993).

130. Moluccan King-parrot

Alisterus amboinensis

French: Perruche tricolore **German:** Amboinasittich **Spanish:** Papagayo Moluqueño
Other common names: Ambon/Amboina King-parrot/Parrot

Taxonomy. *Psittacus amboinensis* Linnaeus, 1766, Ambon.

Genus has occasionally been lumped with *Aprosmictus*. Forms a superspecies with *A. chloropterus*. Six subspecies recognized.

Subspecies and Distribution.

A. a. hypophonijs (S. Müller, 1843) - Halmahera in N Moluccas.
A. a. sulaensis (Reichenow, 1881) - Sula Is.
A. a. versicolor Neumann, 1939 - Peleng in Banggai Is.
A. a. buruensis (Salvadori, 1876) - Buru in S Moluccas.
A. a. amboinensis (Linnaeus, 1766) - Ambon and Seram in S Moluccas.
A. a. dorsalis (Quoy & Gaimard, 1830) - W Papuan Is and W Irian Jaya (W New Guinea).

Descriptive notes. 35 cm; 145-163 g. Head to nape and entire underparts red; upper mandible red, lower greyish; wings oil green; underwing-coverts, shoulder, lesser wing-coverts, mantle, back, rump and uppertail-coverts deep blue; tail blackish blue above, greyish below with undertail-coverts black edged red and three outer tail feathers dull pink on inner webs. Legs grey. Immature has green mantle, bill brownish black. Race *sulaensis* has variable green band across mantle, no pink edging on tail; *versicolor* like *amboinensis* but smaller; *buruensis* like *sulaensis* but pink retained, no red in bill; *hypophonijs* has wings deep blue,

no pink on tail; *dorsalis* like *amboinensis* but no pink on tail.

Habitat. Canopy and lower stages of dense primary and secondary forest from lowlands at 200-350 m to around 1400 m; on Buru, found mainly at 1100-1500 m, but this is where the only primary forest remains, so may not be a genuine habitat preference. Occasionally at the edge of gardens and plantations; found in forest on poor soils on Halmahera, where apparently intolerant of habitat disturbance. Quiet behaviour in mid-canopy recalls Neotropical trogons (*Trogon*).

Food and Feeding. Buds, seeds, grain, fruits, berries; recorded taking *Lithocarpus* acorns.

Breeding. Feb-Mar. Nest in hole in large tree. Eggs apparently 2; in captivity, incubation 19 days, nestling period 9 weeks.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. Overall a common species, but despite coloration unobtrusive and difficult to detect. Rare and threatened on Halmahera; confined to primary forest areas on Taliabu (Sula Is), where perhaps 5000 birds survive. Surveys on Seram and Buru in 1991 suggested densities of 8 birds/km² in primary forest and 52 birds/km² in logged forest; the population of race *amboinensis* alone may then have been 70,000 birds. Trade pressure not great owing to exceptionally high post-capture mortality rates, but quotas set for different subspecies do not appear to reflect their known status, rather the desires of the trading community, so baseline survey and monitoring needed throughout range.

Bibliography. Andrew (1992), Anon. (1993), Beehler *et al.* (1986), Bowler & Taylor (1989), Burgess (1976), Coates & Bishop (1997), Davidson *et al.* (1995), Dingle (1981), Eck (1977), Gyldestolpe (1955b), Harrison & Holyoak (1970), Hoogerwerf (1971), Jepson (1993), Marsden (1995), Rand & Gilliard (1967), Siebers (1930), Smiet (1985), Stresemann (1914), White & Bruce (1986).

131. Papuan King-parrot

Alisterus chlorocephalus

French: Perruche à ailes vertes

German: Papuasittich

Spanish: Papagayo Papú

Other common names: Green-winged King-parrot

Taxonomy. *Aprosmictus chlorocephalus* E. P. Ramsay, 1879, Goldie River, New Guinea.

Genus has occasionally been lumped with *Aprosmictus*. Forms a superspecies with *A. amboinensis*. Three subspecies recognized.

Subspecies and Distribution.

A. c. moszkowskii (Reichenow, 1911) - N New Guinea.

A. c. callopterus (D'Alberty & Salvadori, 1879) - C New Guinea from Weyland Mts to R Fly.

A. c. chlorocephalus (E. P. Ramsay, 1879) - E New Guinea.

Descriptive notes. 36 cm; 138-190 g. Similar to *A. amboinensis* but hindcrown and nape deep blue, mantle and scapulars black, lesser and median wing-coverts greenish yellow forming large wing patch. Female has head, back, wings and underwing-coverts olive green, breast the same with reddish edges; tail green above, blackish distally. Immature like female but without reddish edges on breast, bill brownish. Race *callopterus* restricts blue above mantle to narrow nuchal band; *moszkowskii* male and female like male *callopterus*, female with mantle and back olive green.

Habitat. Shaded interior of hill rain forest, middle storey to lower canopy; less commonly in monsoon forest and second growth up to c. 2300 m, and occasionally higher or down at sea-level.

Food and Feeding. Berries, small seeds of composites, *Casuarina* fruit.

Breeding. No clear information; gonadal development in Jun and Jul, and a juvenile taken in Sept.

Movements. Apparently sedentary.

Status and Conservation. Not globally threatened. CITES II. Generally scarce and in low numbers, though locally common and probably underrecorded owing to highly unobtrusive behaviour; thus in one intensively studied lower-lying area density was estimated at 30 birds/km². A total of 3382 birds were reported in international trade in period 1987-1992, virtually all originating in Indonesia where no population data exist; however, quotas greatly reduced in mid-1990's.

Bibliography. Andrew (1992), Beehler (1978b), Beehler *et al.* (1986), Bell (1982), Campbell (1981), Clapp (1987a), Coates (1985), Cooke (1992), Diamond (1972a), Gilliard & LeCroy (1961), Gregory (1995a, 1995b), Hodges (1989), Mayr & Rand (1937), Rand & Gilliard (1967), Ripley (1964), Rothschild (1931), Schmid (1993), Sweeney (1995a).

Genus APROSMICTUS Gould, 1843

132. Olive-shouldered Parrot

Aprosmictus jonquillaceus

French: Perruche jonquille

German: Timorsittich

Spanish: Papagayo de Timor

Other common names: Timor (Red-winged) Parrot

Taxonomy. *Psittacus jonquillaceus* Vieillot, 1818, New Holland; error = Timor.

Forms a superspecies with *A. erythropterus*. Two subspecies recognized.

Subspecies and Distribution.

A. j. wetterensis (Salvadori, 1891) - Wetar.

A. j. jonquillaceus (Vieillot, 1818) - Timor and Roti.

Descriptive notes. 35 cm. Similar to female *A. erythropterus* but brighter, more yellowish green on head and body, darker mantle and upper back with blue margins, bend of wing blue, inner median and lesser wing-coverts yellow. Female lacks blue on mantle and back, and blue, red and yellow on wing. Immature like female but without yellow in wing. Race *wetterensis* smaller, with little yellow and less red in the wing.

Habitat. Primary and secondary monsoon forest, savanna woodland, lightly wooded cultivation, and scrubby secondary growth, up to 2200 m.

Food and Feeding. No information available.

Breeding. No information available.

Movements. No information available.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. Fairly common, although habitat destruction has somewhat restricted its range. Small numbers present on Wetar, 1989. Trade levels were not excessive in 1980's, but in 1990's zero quotas, recommended while uncertainty exists over total population size, have been flouted.

Bibliography. Andrew (1992), Anon. (1993), Coates & Bishop (1997), Collar *et al.* (1994), Johnstone & Jepson (1996), Mayr (1944b), Mees (1975), Noske (1995), Robson (1990b), Verheijen (1976), Wheatley (1996), White & Bruce (1986).

133. Red-winged Parrot

Aprosmictus erythropterus

French: Perruche érythroptère

German: Rotflügelsittich

Spanish: Papagayo Alirrojo

Taxonomy. *Psittacus erythropterus* J. F. Gmelin, 1788, Cooktown, northern Queensland.

Forms a superspecies with *A. jonquillaceus*. Two subspecies recognized.

Subspecies and Distribution.

A. e. coccineopterus (Gould, 1865) - S New Guinea and N Australia.

A. e. erythropterus (J. F. Gmelin, 1788) - interior E Australia.

Descriptive notes. 30-32 cm; 156 g. Green on head, nape, underparts and rump; bill orange red; mantle, upper back and secondaries greenish black; lesser, median and secondary coverts red; primaries and tail dark green, latter tipped yellow; lower back deep blue. Female duller, with reduced red in wing and no greenish black. Immature like female. Race *coccineopterus* smaller, with blue wash on hindcrown.

Habitat. In Australia open *Eucalyptus* forest, riverine thickets, *Melaleuca* woodland, arid *Acacia* scrubland, *Casuarina* and *Callitris* groves in rocky country, and mangroves; in

New Guinea subcoastal wooded savanna. Rarely far from water.

Food and Feeding. Preference shown for seeds of eucalypts, acacias and hopbush (*Dodonea*), plus mistletoe *Loranthus* berries and *Grevillea* blossoms; fruits of *Geijera parviflora*, seeds of *Cochlospermum fraseri*, *Amyema preissii*, *Gahnia*, *Crotalaria* and *Schinus areira* also noted, as well as other seeds, nuts, fruits, blossoms, nectar and insects such as lerps *Spondylaspis eucalypti* and curculionid larvae. Visits croplands to feed on ripening grain.

Breeding. Aug-Feb generally, but Apr-Jul in NE Australia. Nest high in hollow limb or deep hole in tree, often a waterside eucalypt. Eggs 3-5, sometimes 6; incubation, by female only, lasts c. 3 weeks; nestling period c. 5 weeks.

Movements. Relatively sedentary in climatically more stable regions, but rather nomadic elsewhere with irregular movements along fringes of range in Australia. Reports of large flocks in New Guinea suggest seasonal movements there.

Status and Conservation. Not globally threatened. CITES II. Generally common, locally abundant, and possibly benefiting from forest clearance in parts of Australia, where sometimes illegally persecuted due to crop depredations. International trade up to 1987 consisted of several hundred birds annually, but after 1987 numbers doubled, with 1144 exported in 1990, all birds coming from Indonesia; at around this time evidence of systematic trapping was encountered, and quotas, although not exceeded, appeared to have no biological basis.

Bibliography. Anon. (1993), Beehler *et al.* (1986), Bellchambers *et al.* (1994), Blakers *et al.* (1984), Coates (1985), Courtney (1997a), Edwards & Nash (1992), Hall (1974), Hoogerwerf (1964a), Ley (1993), Lindsey, T.R. (1992), Macdonald (1988), Mayr & Rand (1937), Mees (1982a), Pfeffer (1985), Pizzey & Doyle (1980), Rand (1942a), Rand & Gilliard (1967), Schodde & Tidemann (1986), Simpson & Day (1996), Thomson (1935), Trounson & Trounson (1987), Vriends (1979), White (1922).

Genus POLYTELIS Wagler, 1832

134. Superb Parrot

Polytelis swainsonii

French: Perruche de Barraband

German: Schildsittich

Spanish: Perico Soberbio

Other common names: Barraband/Green Leek Parrot

Taxonomy. *Psittacus Swainsonii* Desmarest, 1826, New South Wales.

Forms a parapatric species pair with *P. anthopeplus*. Monotypic.

Distribution. Interior SE Australia chiefly along the river systems of Murrumbidgee and Castlereagh.

Descriptive notes. 40 cm; 133-157 g. Green, with pinkish red bill, yellow forehead to mid-crown tinged blue on hindcrown; yellow lower face, chin and throat with a broad red band across forehead; outer webs of primaries dull blue, underside of tail black. Female all green, bluish on face, with reddish thighs and undersides of lateral tail feathers. Immature similar.

Habitat. Riverine eucalypt woodland dominated by red gum (*Eucalyptus camaldulensis*), also penetrating well-watered open forest and groves in pastures in E of range. Nest-site distribution correlated with breeding-season foraging habitat, i.e. woodland of yellow box (*Eucalyptus melliodora*), white cypress pine (*Callitris columellaris*) and borree (*Acacia pendula*).

Food and Feeding. Seeds of grasses, herbs and bushes, e.g. *Erodium*, *Stipa*, *Danthonia*, *Hordeum murinum*, *Medicago denticulata*, *Acacia armata*, heads of *Sonchus oleraceus*, *Sisymbrium* and *Capsella*; in winter lerps, mistletoe berries, *Eucalyptus* blossoms and grass seed. Sometimes takes wheat from stubble, and spilt grain at roadsides.

Breeding. Sept-Dec. Nest is situated in hollow limb or hole in tree, generally high (11-51 m) over water in a riverine eucalypt; often colonial. Eggs 4-6; incubation lasts c. 20 days; nestling period c. 30 days.

Movements. N parts of range only occupied by part of population in winter, Apr-Aug; yet also evidence of local southward movement of birds in CW New South Wales, Jun. Birds also partly nomadic, moving in search of flowering eucalypts.

Status and Conservation. VULNERABLE. CITES II. A BirdLife "restricted-range" species. Numbers apparently tumbled in 1920's as an accidental effect of a crop-protection poisoning scheme aimed at *Eolophus roseicapillus* and rabbits, although trapping for the cagebird market was also perhaps significant. Total breeding population, apparently confined to S of range, under 5000 pairs and threatened by decline in availability of nest-sites, degradation and loss of foraging habitat, and probably heavy trapping (birds breed well and captive population in Australia c. 20,000). The species has been recorded from 11 conservation reserves.

Bibliography. Blakers *et al.* (1984), Collar *et al.* (1994), Courtney (1997a), Emison *et al.* (1987), Forshaw (1981b), Frith & Calaby (1953), Garnett (1993), Kaveney (1979), Lindsey, T.R. (1992), Macdonald (1988), Pizzey & Doyle (1980), Schodde & Tidemann (1986), Schrader (1980), Simpson & Day (1996), Tronson & Tronson (1987), Vriends (1979), Webster (1988, 1992).

135. Regent Parrot

Polytelis anthopeplus

French: Perruche mélanure **German:** Bergsittich **Spanish:** Perico Regente
Other common names: Rock Peppler

Taxonomy. *Palaeornis anthopeplus* Lear, 1831, no locality = New South Wales; error, now replaced by Boigart, c. 40 km north of Toodyay, south-west Australia.

Forms a parapatric species pair with *P. swainsonii*. Eastern race erroneously listed as nominate in past, with western birds placed in race *westralis*. Two subspecies recognized.

Subspecies and Distribution.

P. a. anthopeplus (Lear, 1831) - SW Australia.

P. a. monarchoides Schodde, 1993 - interior W part of SE Australia.

Descriptive notes. 40 cm; mean 114 g. Bill pinkish red; head pale yellowish olive, shading to dark olive on mantle, back and scapulars; underparts, rump and lesser and median wing-coverts bright yellow; remainder of wing blackish except for broad red band on inner secondaries; tail blue-black. Female duller and much greener. Immature similar. Race *monarchoides* has less olive head and breast.

Habitat. In SE Australia, flooded-zone *Eucalyptus* woodland and adjacent arid mallee scrublands, with breeding always taking place within 20 km of mallee or cultivated land; in

SW, most types of wooded land including partly cleared areas in dense coastal forest.

Food and Feeding. In SE of range formerly fed extensively on seeds of native hops *Dodonaea attenuata* and *D. viscosa*, now much reduced by human settlement; still feeds primarily in mallee, on seeds of *Eucalyptus*, *Acacia*, grasses (five wild Poaceae recorded) and herbaceous plants (five Asteraceae, four Chenopodiaceae, two Cucurbitaceae, two Dilleniaceae), plus fruits (e.g. *Ficus* and *Amyema* mistletoe), leaf buds, blossoms and green shoots; also wheat and cultivated fruits, thus sometimes a crop pest in fields, vineyards and orchards.

Breeding. Aug-Jan, also May. Usually in small loose colonies of up to 67 pairs; of 57 nests in one study, 45 were within 150 m of another nest. Nest in often deep hollow in main trunk of tree, commonly salmon gum (*Eucalyptus salmonophloia*) and wandoo (*E. wandoo*) in SW Australia, *E. camaldulensis* in SE; hole always above 4 m, and sites always within 5 km of blocks of mallee. Eggs 4-6; incubation lasts 21 days; nestling period c. 6 weeks.

Movements. Northward post-breeding dispersal in SE Australia, while in SW there is evidence of seasonal (commoner May-Dec than Jan-Mar), irruptive and nomadic behaviour, apparently depending on regularity of rains, with certain well-watered core areas being occupied year-round.

Status and Conservation. Not globally threatened. CITES II. Now very uncommon in SE Australia, retreating before clearance of mallee for agriculture, but abundance in fact initially increased in SW as a result of human occupation of the wheatbelt, with flocks of up to 100 reported. However, substantial decline since 1940's throughout the wheatbelt, probably as a result of loss of nest-sites, possibly compounded by an open season in five shires of Western Australia to control numbers invading croplands; recent signs of increasing numbers. Poor regeneration of nest-trees is certainly a long-term cause for concern; the species needs large, old gums near water, and additionally these must be acceptably close to feeding habitat. Competition for nest-sites with feral honey bees appears not to be significant, but there is some overlap in site preference. In SE Australia, roadkills while taking spilt grain common, and occupation of nests by feral bees problematic.

Bibliography. Beardsell (1985), Blakers *et al.* (1984), Burbidge (1985), Courtney (1997a), Emison *et al.* (1987), Forde (1990), Forshaw (1981b), Garnett (1993), Harper (1989), Joseph (1978), Lindsey, T.R. (1992), Long & Mawson (1994), Macdonald (1988), Masters & Milhinch (1974), Mawson & Long (1994), Oldroyd *et al.* (1994), Pizzey & Doyle (1980), Saunders & Ingram (1995), Schodde (1993), Schodde & Tidemann (1986), Sedgwick (1949), Serventy & Whittell (1976), Shields (1983), Simpson & Day (1996), Sontter (1984), Tronson & Tronson (1987), Vriends (1979).

136. Princess Parrot

Polytelis alexandrae

French: Perruche d'Alexandra **German:** Alexandrasittich **Spanish:** Perico Princesa
Other common names: Alexandra's Parrot, Princess of Wales Parakeet

Taxonomy. *Polytelis alexandrae* Gould, 1863, Howell's Ponds, Central Australia.

Monotypic.

Distribution. Interior W & C Australia.

Descriptive notes. 45 cm. Bill pinkish red, yellow at tip; crown to nape soft pale blue, merging on neck into light olive brown of mantle, back and scapulars; area from upper mandible to behind eye buffy green; chin, lower cheeks, throat and upper breast pink; lower breast to belly olive yellow tinged greyish blue between thighs, with some pink on thighs; wing-coverts grass green except primary coverts purple; flight-feathers olive green with yellow outer edges to primaries; lower back and rump mauve; tail light grey-green with yellow, red, grey and black in outer feathers. Female has greyish crown and rump, smaller

area of pink on breast, somewhat duller. Immature similar.

Habitat. Sandy deserts with hummock grassland of *Triodia* and *Plectrachne*, usually with a shrub layer, stands of *Casuarina* in sandy country, *Acacia* scrublands and eucalypts, notably *Eucalyptus camaldulensis*, bordering watercourses, this last commonly used for nesting.

Food and Feeding. Seeds of grasses and herbaceous plants, notably spinifex, but also *Danthonia bipartita*, *Portulaca oleracea*, *Stenopetalum anfractum*, *Rhynchelytrum repens* and *Calandrinia*; seeds and perhaps blossoms of *Acacia* and *Casuarina*, taking green leaflets of latter, and seen feeding on leaves of *Codonocarpus cotinifolius*, flowers of *Crotalaria cunninghami*, *Grevillea wickhamii* and *Hakea suberea*.

Breeding. Recorded Sept-Dec, but dependent young also seen in Jul; probably at any time of year after rainfall. Nest in hollow limb or hole in tree, usually a riverine eucalypt but sometimes *Casuarina*; sometimes colonial, with up to 10 nests in one tree. Eggs 4-6; incubation lasts c. 21 days.

Movements. Irruptive and/or nomadic; recent analysis suggests a core population around Lake Tobin, in the east of the Great Sandy Desert, from which birds range out far more widely over several years when conditions permit.

Status and Conservation. VULNERABLE. CITES II. Population very difficult to assess in a very scarce, apparently nomadic species with a large range; possibly no major decline but decline and extinction of other sympatric non-avian taxa, and absence of records of large numbers since 1963, caused concern; in Jul 1993 almost 300 were counted in one part of the Lake Tobin area. Possible that man-made changes to its habitat may have favoured more water-dependent competitors. No fewer than 25,000 held in captivity in Australia.

Bibliography. Allen (1987), Blakers *et al.* (1984), Brouwer & Garnett (1990), Carter (1993), Collar & Andrew (1988), Collar *et al.* (1994), Courtney (1997a), Emmett (1987), Fitzherbert & Baker-Gabb (1988), Forshaw (1981a, 1981b), Garnett (1993), Hobcroft (1993), Lindsey, T.R. Genus *PSITTACULA* Cuvier, 1800

137. Alexandrine Parakeet

Psittacula eupatria

French: Perruche alexandre **German:** Großer Alexandersittich **Spanish:** Cotorra Alejandrina

Taxonomy. *Psittacus Eupatria* Linnaeus, 1766, Gingi, India. Some of currently accepted races may be representative of clines, with race *nipalensis* particularly weak. Five subspecies currently recognized.

Subspecies and Distribution.
P. e. nipalensis (Hodgson, 1836) - E Afghanistan and Pakistan E through N India to Bangladesh.
P. e. eupatria (Linnaeus, 1766) - S India and Sri Lanka.
P. e. magnirostris (Ball, 1872) - Andaman Is.
P. e. avensis (Kloss, 1917) - Assam (NE India) and N Myanmar.
P. e. siamensis (Kloss, 1917) - W & N Thailand E to C Indochina.

Descriptive notes. 50-62 cm; 198-258 g. Bill red; head green shading to grey on nape and lower face; black chin and malar bar to side of neck where replaced by broad pink-red bar round hindneck; upper body yellow-green shading deeper on wings and belly; long reddish patch on lesser wing-coverts; tail green basally shading through pale blue-green to yellowish tip, with outer feathers green with yellowish tips. Female duller, with no black on chin or pink collar. Immature like female. Race *nipalensis* larger, purportedly with more blue than grey in head; *magnirostris* has larger bill, narrow blue band above pink collar.

brighter wing-patch; *avensis* has yellowish neck; *siamensis* has yellowish green face and neck, with blue wash on nape; last three all have narrower black markings on chin and neck.

Habitat. Dry and moist deciduous lowland forest and wooded areas including mangroves, coconut plantations and old gardens, penetrating desert regions where trees grow by water, normally rising to 800 m, in places at least occasionally to 1600 m, occupying subtropical pine zone of *Pinus roxburghii* in Pakistan; at least formerly occupied mangroves in the Sunderbans, Bangladesh.

Food and Feeding. Fruits, e.g. guavas (*Psidium guajava*), and seeds, nectar of *Salmalia*, *Butea* and *Erythrina*, fleshy petals of *Bussia latifolia*, and young leaves of vegetables. Flocks do considerable damage in orchards and ripening cereal crops. Over 70% of food in stomachs of birds from agricultural area, W Pakistan, was from cultivated sources.

Breeding. Nov-Apr. Nest in hole in coconut palm or large softwood like *Salmalia*, sometimes the hardwood *Shorea* and *Dalbergia*, and mangroves *Sonneratia* and *Heritiera*; *Terminalia* recorded in Sri Lanka. Normally 3-4 eggs, but 2-3 in Andamans; incubation 19-21 days.

Movements. Resident, but also nomadic and locally migratory in N India.

Status and Conservation. Not globally threatened. CITES II. Nominate race common in Pakistan, relatively sparse in India, and has declined steeply in Sri Lanka, where now rare and mainly confined to the N. However, forms in N Indian subcontinent and on Andamans common, and much used locally as pets. Apparently only in modest numbers in Myanmar. In Thailand nest robbery is exterminating the population. Seemingly scarce, probably for similar reasons, in Indochina, and in 1995 absent from at least one area where formerly common.

Bibliography. Abdulali (1964, 1981), Ali (1996), Ali & Ripley (1981), Beaman (1994), Deignan (1945), Delacour & Jabouille (1931), Eates (1937), Harvey (1990), Heydon (1929), Hoppe (1987), Inskipp & Inskipp (1991), Jennings (1992), Kotagama (1985), Lekagul & Round (1991), Luft (1994), Majumdar *et al.* (1992), Phillips (1978), Puget (1970), Ripley (1982), Roberts, T.J. 138. Rose-ringed Parakeet

Psittacula krameri

French: Perruche à collier **German:** Halsbandsittich **Spanish:** Cotorra de Kramer
Other common names: Ring-necked Parakeet

Taxonomy. *Psittacus krameri* Scopoli, 1769, Senegal. Four subspecies recognized.

Subspecies and Distribution.
P. k. krameri (Scopoli, 1769) - S Mauritania, Senegal and Guinea E to W Uganda and S Sudan.
P. k. parvirostris (Sourance, 1856) - CE Sudan through Ethiopia, Eritrea and Djibouti to NW Somalia.
P. k. borealis (Neumann, 1915) - NW Pakistan E through N India, Nepal and C Myanmar to SE China (Guangdong); reportedly once in Indochina.
P. k. manillensis (Bechstein, 1800) - Peninsular India S of 20° N, and Sri Lanka.

Feral in many cities and their environs in Africa, Arabia, W Palearctic and W Asia (some populations of these might conceivably be natural); also Mauritius, Hong Kong, Macao and Singapore, and apparently USA; unclear which races involved, although often attributed to *borealis*.

Descriptive notes. 37-43 cm; 95-143 g. Pale yellowish green, with upper mandible dark red tipped black, lower black, with black chin and malar area curving and narrowing into half-collar on side of neck, where bordered below by a narrow rose pink line that extends over nape, above by indistinct mauve-blue extending onto hindcrown; flight-feathers dusky green above, grey below; tail bluish green on central feathers, ochrish below. Female lacks blue, pink and black on head but can show emerald collar. Immature like female but yellower, with no or indistinct collar. Race *parvirostris* darker, with stronger pink collar in male, upper mandible all red; *borealis* larger and more greyish below, with more blue on head, bill usually all red; *manillensis* like *borealis* with black lower mandible.

Habitat. Chiefly deciduous habitats ranging from semi-desert to light secondary jungle, mainly in lowlands but ranging in Asia up to 1600 m and in Ethiopia to c. 2000 m. Short-grass and semi-desert savanna, open scrub and bushland, wooded valleys, savanna woodland, riparian and evergreen forest, foothill pine zone in *Pinus roxburghii*, open agricultural land with scattered trees, gardens, orchards, cultivations, often also grain yards at entrepôts and railway stations.

Food and Feeding. In Africa, recorded fruits include *Ficus*, *Ziziphus*, *Tamarindus*, guavas, dates, mangoes, baobab, seeds of *Acacia albidia* and *Slassus*, plus cultivated seeds and nuts of millet, sorghum, lentils, guinea-corn, groundnuts, oil-palms, coffee. In Asia, specific items identified include seeds of *Prosopis speiagera*, *Acacia arabica*, *Casuarina equisetifolia*, fruit of *Dalbergia sissoo*, *Ficus*, *Acacia*, *Ziziphus*, *Xanthium*, *Melia azedarach*, *Azadirachta indica* and *Albizia lebbek*, flowers and fruit of *Capparis aphylla*, flower petals and nectar of *Salmalia malabarica*, *Erythrina indica*, *Butea monosperma*, *Bassia latifolia*. In Asia, especially India, regarded as one of the most destructive bird pests in agriculture, coming in enormous flocks to cereals and fruit crops, especially *Citrus* and *Prunus*; however, in one area, guavas (*Psidium guajava*) were the favoured cultivated fruit, with maize eaten Sept-Dec, ground-nuts Nov-Mar and May-Jun, and wheat Mar; in another, pearl millet, sorghum and maize were greatly consumed Aug-Dec, guava Jan-Mar and Jul-Aug, mulberry (*Morus alba*) seeds Apr-May. Coffee, chillie, sunflowers, mustard, pepper and gram also attacked; will tear open sacks. Feral birds in UK take fruits and berries of Rosaceae, *Ilex*, *Sambucus*, nuts of *Fagus*, *Aesculus*, *Carpinus*, *Fraxinus*, *Pinus*, cultivated fruit and cereals, food at bird-tables; feral birds in Arabia take dates, grain, seeds of sunflower and *Caesalpinia*.

Breeding. Dec-May in W Africa and probably also Arabian Peninsula (possibly introduced); in Nigeria, nesting attempted in May, but failed owing to aggression by Red-billed Hornbills (*Tockus erythrorhynchus*); Sept in South Africa, in willow trees over a large pool; Jan-Apr, sometimes to Jul, in Asia; Jan-Jun in UK (introduced). Nest in hollow in tree, usually enlarged by birds themselves, 3-10 m up, but sometimes in rock faces or ruined walls; often loosely colonial. Eggs usually 3-4, rarely 6; incubation lasts 22 days; nestling period 7 weeks.

Movements. Resident, but subject to minor local movements in Africa, e.g. recorded throughout year in Ouagadougou, Burkina Faso, except Jun, and a rainy season visitor (Aug-Nov) to parts of S Mauritania. Also irregular in Ghana and one part of Central African Republic.

Status and Conservation. Not globally threatened. CITES III (Ghana). Common to abundant throughout natural range and in many places where introduced, e.g. Mauritius, and generally increasing in numbers and range, partly through introductions and escapes, partly through use of spreading agriculture and horticulture. Introduced to but died out from Zanzibar, loss being attributed to House Crows (*Corvus splendens*). Noted as a crop pest at start of century. Ghana, and now recognized as such throughout its range, including areas where introduced such as South Africa. Only fairly common, Myanmar; very rare in limited range, China.

139. Mauritius Parakeet

Psittacula echo

French: Perruche de Maurice **German:** Mauritiussittich **Spanish:** Cotorra de Mauricio
Other common names: Echo Parakeet

Taxonomy. *Palæornis echo* A. and E. Newton, 1876, Mauritius. Has been treated as a race of *P. krameri*, or of extinct *P. eques* from Reunion; name *echo* even regarded as a junior synonym of *eques*, being indistinguishable from descriptions of the latter, of which no specimens survive. Monotypic.

Distribution. Mauritius.

Descriptive notes. 36-42 cm; 167-193 g. Very similar to *P. krameri* but darker, richer green, with bluish wash on nape, tail greener above, shorter. Female like female *krameri* but darker, more emerald green, and bill all black. Immature like female.

Habitat. Native lowland and upland forest and scrublands, formerly in lightly wooded, i.e. heavily degraded country; now favours areas with largest remaining native trees such as *Canarium mauritanum*, *Syzygium contractum*, *Mimusops maxima* and *Labourdonnaisia*.

Food and Feeding. Fruit of native plants such as *Calophyllum*, *Tabernaemontana*, *Labour-*

On following pages: 140. Slaty-headed Parakeet (*Psittacula himalayana*); 141. Grey-headed Parakeet (*Psittacula finschii*); 142. Intermediate Parakeet (*Psittacula intermedia*); 143. Plum-headed Parakeet (*Psittacula cyanocephala*); 144. Blossom-headed Parakeet (*Psittacula roseata*); 145. Malabar Parakeet (*Psittacula columboides*); 146. Emerald-collared Parakeet (*Psittacula calthropae*); 147. Derbyan Parakeet (*Psittacula derbiana*); 148. Red-breasted Parakeet (*Psittacula alexandri*); 149. Nicobar Parakeet (*Psittacula caniceps*); 150. Long-tailed Parakeet (*Psittacula longicauda*).

donnaisia, *Mimusops*, *Syzygium*, *Sideroxylon*, *Nuxia*, *Diospyros*, *Eugenia* and *Erythrospermum*, plus some introduced species. More leaves consumed in winter when fruit scarcer.

Breeding. Sept-Feb. Nest in rain-sheltered hole at least 10 m up in hollow limb of old, usually living tree, notably *Mimusops* but also *Calophyllum*, *Canarium* and *Sideroxylon*. Eggs 2-4, normally with 2 young being raised; incubation probably c. 22 days; nestling period around 9 weeks.

Movements. Sedentary; birds may formerly have shifted areas quite extensively with seasonal changes in foods, in particular when cyclones stripped fruit from trees.

Status and Conservation. CRITICALLY ENDANGERED. CITES I. A BirdLife "restricted-range" species. Almost total clearance of forest on Mauritius has confined the remaining population to small area of native vegetation in the mountainous SW, based on Black River Gorges, now a national park. Illegal hunting, nest predation and food competition by macaques, nest-site competition from introduced *P. krameri* and Common Mynas (*Acridotheres tristis*), and the impact of cyclones on food supplies and nest-sites were all implicated in the extinction vortex this species appeared to have entered in the 1970's and 1980's, during which time there was almost total breeding failure and the population was believed to be around 10 individuals. Some breeding success since then has resulted in numbers rising to 16-22 in 1993-1994, with a pair in captivity also producing offspring; by 1996 there were 13 breeding groups (pairs and helpers) in the wild, i.e. 40-50 birds in total, and first clutches were being taken for captive rearing and subsequent release, in order to maximize current reproductive output. Including captive birds, overall total now stands at c. 85-90 birds.

Bibliography. Ahimaz (1984, 1987), Anon. (1984, 1996d), Cheke (1987), Cheke & Jones (1987), Collar & Andrew (1988), Collar & Stuart (1985), Collar *et al.* (1994), Diamond, A.W. (1985a), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Greenwood (1997), Hachisuka (1953), Hartley (1993), Horne (1987), Hume (1996), Jones, C.G. (1980a, 1980b, 1981, 1982, 1987), Jones, C.G. & Duffly (1992, 1993), King (1978/79), Lovegrove (1995), Low (1994b, 1997e), Meinertzhagen (1912), Newton (1958), Procter & Salm (1974), Rountree *et al.* (1952), Sargeant (1992), Staub (1971), Steele (1979), Swinnerton (1995), Temple (1974, 1976, 1978a), Temple *et al.* (1974), Williams, S. (1995, 1997), Young (1987).

140. Slaty-headed Parakeet

Psittacula himalayana

French: Perruche de l'Himalaya **German:** Himalayasittich **Spanish:** Cotorra del Himalaya
Other common names: Himalayan (Slaty-headed) Parakeet

Taxonomy. *Psittacus* (*Conurus*) *Himalayanus* Lesson, 1832, valleys of the Himalayas. Formerly considered conspecific with *P. finschii*. Monotypic.

Distribution. Himalayas from Afghanistan and W Pakistan E through N India and Nepal to Bhutan and W Assam.

Descriptive notes. 39-41 cm. Upper mandible red tipped yellow, lower yellow; head slate grey with black half-collar from chin and throat up sides of neck; body yellowish green, tinged bluish on upperparts; wings green with maroon patch on lesser wing-coverts; tail green basally shading through blue to yellow distally. Immature green with cheeks brownish, bill greyish.

Habitat. Subtropical coniferous and deciduous woodlands, especially deodar (cedar) forest, cultivated areas with large trees, 600-2500 m, generally above 1350 m.

Food and Feeding. Camphor (*Cinnamomum*),

Cornus, *Viburnum* and *Duranta* berries, acorns of *Quercus dilatata*, seeds of *Rhus cotinus*, *Terminalia myriocarpa* and *Populus ciliata*, flowers of *Bauhinia purpurea*, *Woodfordia fruticosa*, *Bombax ceiba* and *Pistacia integerrima*, and pods of *Dalbergia*. In some places birds raid walnut, apple and pear orchards, and cornfields.

Breeding. Mar-Jul, staggered with altitude. In Afghanistan old nesting holes of Scaly-bellied Woodpecker (*Picus squamatus*) commonly used, while in Pakistan use of *Quercus dilatata* common; usually colonial. Eggs 3-5; in captivity, incubation 24 days, nestling period c. 40 days.

Movements. Nomadic in E Afghanistan, but elsewhere clear movements occur to lower-lying areas in winter, often first targeting cultivated areas, and in Pakistan the period spent on breeding grounds is Mar-Aug.

Status and Conservation. Not globally threatened. CITES II. Generally common, but apparently very poorly documented in recent decades; uncommon in China.

Bibliography. Ali (1996), Ali & Ripley (1981), Ali *et al.* (1996), Bates & Lowther (1952), Beaman (1994), Biswas (1960), Cheng Tsohsin (1987), Evans, M.J. (1994), Fleming (1967), Gauntlett (1972), Grewal (1995), Hùe & Etchécopar (1970), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Puget (1970), Ripley (1982), Roberts, T.J. (1991), Sedgemoor (1995), Vaurie (1965), Vieillard (1969), Wright (1957).

141. Grey-headed Parakeet

Psittacula finschii

French: Perruche de Finsch **German:** Finschsittich **Spanish:** Cotorra de Finsch
Other common names: Finsch's/Hume's/Eastern Slaty-headed Parakeet

Taxonomy. *Palaeornis Finschii* Hume, 1874, Kollidoo, 3500-5000 feet (c. 1000-1500 m), upper Salween River, Myanmar.

Long considered conspecific with *P. himalayana*, but the two recorded within 25 km of each other in N Bengal and SE Bhutan; however, other evidence suggests birds are convergent in this region, while the close geographical approach of two more distinct forms may simply reflect migration; separation as two species remains provisional. Monotypic.

Distribution. India from W Bengal E through Bangladesh, S China, Myanmar and Thailand to Indochina.

Descriptive notes. 36-40 cm. Very similar to *P. himalayana* but smaller with longer tail feathers, slightly paler head, yellower upperparts and darker blue-green underwing-coverts. Immature all green.

Habitat. Open mixed deciduous forest, teak forest, secondary growth, cultivation and tea plantations in foothills at 600-1200 m, though recorded down to 100 m in Assam and up to 3800 m in China; in Indochina apparently more strictly associated with forest.

Food and Feeding. Leaf buds and developing cherry (*Prunus*) fruit, letpan flowers and flowering climbers, seeds of *Dendrocalamus longispatus* and various figs, grains.

habitat clearance but this remains poorly documented. Birds occur in local markets in Vietnam, and 917 were recorded in international trade, 1987-1992, most coming from Myanmar.

Bibliography. Ali & Ripley (1981), Ali *et al.* (1996), Bangs & Van Tyne (1931), Beaman (1994), Cheng Tsohsin (1987), David-Beaulieu (1944), Deignan (1945), Delacour & Jabouille (1931), Etchécopar & Hùe (1978), Harvey (1990), Husain (1959b), Inskipp *et al.* (1996), Khan (1981), Lekagul & Round (1991), Ripley (1982), Robson *et al.* (1989), Round (1988), Smythies (1986), Stepanyan (1995), Vaurie (1965).

142. Intermediate Parakeet

Psittacula intermedia

French: Perruche intermédiaire **German:** Mittelsittich **Spanish:** Cotorra Intermedia
Other common names: Rothschild's Parakeet, Intermediate Parrot

Taxonomy. *Palaeornis intermedia* Rothschild, 1895, India.

Status controversial owing to uncertainty over range and the increasing probability of its representing hybrid *P. himalayana* x *P. cyanocephala*, for which the evidence is becoming extremely convincing. Monotypic.

Distribution. Reportedly from the Mattiyar and Varanasi regions in the plains of Uttar Pradesh, NC India.

Descriptive notes. 36 cm. Intermediate between *P. himalayana* and *P. cyanocephala*, with upper mandible orange-red, lower mandible yellow to black, area from forehead to behind and around eye rufous-purple, rest of head slaty purple, back yellowish green, rump green tinged blue, tail with yellowish white tips to central feathers, outer webs of outer feathers bluish green with yellow tips. Immature undescribed.

Habitat. Unknown.

Food and Feeding. Unknown.

Breeding. Unknown.

Movements. Unknown.

Status and Conservation. VULNERABLE. CITES II. Clearly if this form really has the status of a species then it is a very rare one. Very small numbers of birds are reputedly captured by trappers pursuing the common *Psittacula* parakeets of N India. However, it is becoming increasingly likely that the birds in question are hybrids, although it remains to be established whether they are captive-bred or the result of natural crossing.

Bibliography. Ali & Ripley (1981), Biswas (1959, 1989), Collar & Andrew (1988), Collar *et al.* (1994), Husain (1959a), Inskipp, C. & Inskipp (1995), Inskipp, T. *et al.* (1996), Ripley (1982), Sane (1975), Sane *et al.* (1987), Walters (1985), Wheatley (1996).

143. Plum-headed Parakeet

Psittacula cyanocephala

French: Perruche à tête prune **German:** Pflaumenkopfsittich **Spanish:** Cotorra Ciruela

Taxonomy. *Psittacus cyanocephalus* Linnaeus, 1766, East Indies = Gingi.

Birds decrease clinally in size from N to S, and head and rump become darker, but limits to proposed N subspecies *bengalensis* too indistinct to make the name useful. Monotypic.

Distribution. Indian Subcontinent and Sri Lanka.

Descriptive notes. 33-37 cm; 56-85 g. Bill yellowish above, black below; head crimson shading to greyish plum on mid-crown to nape and ear-coverts; black chin extending as complete narrow collar, shaded blue-green below on back and sides of neck; underparts yellowish green; mantle and back green, shading darker on wing-coverts, with maroon patch on lesser wing-coverts, and darker again on flight-feathers; rump light blue-green, tail blue tipped whitish centrally, green tipped yellow laterally. Female has purplish grey head with no black, instead an indistinct complete narrow yellowish neck-ring, no maroon wing-patch, creamy upper mandible. Immature has green head, orange on forecrown.

Habitat. Moist deciduous forest and wooded habitats and adjacent clearings and cultivated areas in lowlands and hills to c. 1300 m, using pine zone *Pinus roxburghii* in Pakistan foothills.

Food and Feeding. More frugivorous than most *Psittacula* parakeets, and prefer small to large seeds. Fruit of *Ficus* and *Ziziphus*, buds, fleshy petals and nectar of plants such as *Adhatoda vasica*, *Punica granatum*, *Salmalia*, *Butea* and *Bassia*, seeds of thistles *Echinops* and *Cnicus*; feeding in *Casuarina* also noted. Sometimes visits cultivations inside forest in flocks of several hundred, doing much damage to crops including rice, sorghum, maize, vegetables and orchard fruit.

Breeding. Dec-Apr; in Sri Lanka also occasionally Jul-Aug. Nest in hole in tree trunk or bough, often in small colonies within one tree or group of trees; tall *Pinus roxburghii* are favoured in Pakistan, while a *Parkia* recorded in Sri Lanka. Eggs 4-5, rarely 6; in captivity, incubation lasts 24 days, nestling period 6 weeks.

Movements. Resident, but with marked local movements in response to food supply.
Status and Conservation. Not globally threatened. CITES II. Fairly common in Nepal, but with an apparently decline in Kathmandu Valley. In India generally common. Formerly abundant in low-lands of Sri Lanka, but habitat loss has forced range inwards, and now only common at mid-altitudes.
Bibliography. Ali (1996), Ali & Ripley (1981), Biswas (1951b), Chakravarthy & Purna Chandra Tejasvi (1992), Grewal (1995), Henry (1971), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Kotagama (1985), Kotagama & Fernando (1994), Legge (1880), Lever (1987), Lowther (1940), Luft (1994), Majumdar *et al.* (1992), Mukherjee (1995), Phillips (1978), Proud (1949), Rand & Fleming (1957), Ripley (1982), Roberts, T.J. (1991), Saha & Dasgupta (1992), Smith, G.A. (1976), Vriends (1979), Wijesinghe (1994).

144. Blossom-headed Parakeet
Psittacula roseata

French: Perruche à tête rose **German:** Rosenkopfsittich **Spanish:** Cotorra Carirrosa

Taxonomy. *Psittacula roseata* Biswas, 1951, Gunjong, North Cachar, Assam. Formerly considered conspecific with *P. cyanocephala*, and listed as *P. c. rosa* (Boddaert, 1783). Two subspecies recognized.
Subspecies and Distribution.
P. r. roseata Biswas, 1951 - W Bengal, Bhutan, N Assam, Bangladesh and N Myanmar.
P. r. juneae Biswas, 1951 - S Assam and S Myanmar E through Thailand to Indochina; also possibly S China, with a 19th century record based on juveniles that might have been *P. finschi*.

Descriptive notes. 30-36 cm. Very similar to *P. cyanocephala* but has forecrown, cheeks and ear-coverts rosy pink hindercrown to ear-coverts bluish lilac, back and rump green, no bluish green band bordering black collar-line, underwing-coverts green not bluish green, tail shorter with tips of central feathers pale yellow. Female has dull bluish grey head, variable yellow collar. Immature has green head. Race *juneae* generally yellower, with larger red wing-patch.
Habitat. Well-wooded country, open forest and the edges of cultivated clearings, to at least 1000 m.
Food and Feeding. No information.
Breeding. Mar-Apr in Myanmar; nestlings and juveniles for sale Mar-May in Thailand indicate rather longer season. Nest reportedly as in *P. cyanocephala*, but holes in old walls and ruins also used. Nestling period, in captivity, c. 6 weeks.
Movements. Local seasonal movements reported in SW Myanmar, where birds common in Mar-Apr, otherwise scarce.
Status and Conservation. Not globally threatened. CITES II. Apparently abundant in Myanmar around 1900, but now much reduced in numbers, though status better than in Thailand, where habitat loss, trade and general persecution of *Psittacula* parrots as pests have caused the species to become uncommon or rare. International trade records showed 836 birds exported in period 1981-1985, but 6873 in period 1986-1990, chiefly from Vietnam and Thailand, causing concern that local populations may have been affected adversely; around 1930 the species was considered nowhere common in Indochina.
Bibliography. Ali & Ripley (1981), Anon. (1993), Baumgärtner (1997b), Biswas (1951b), Christison *et al.* (1946), Deignan (1945), Delacour & Jabouille (1931), Échécopar & Hüe (1978), Hargreaves (1960), Harrison & Holyoak (1970), Harvey (1990), Inskipp *et al.* (1996), Lekagul & Round (1991), Ripley (1982), Robson *et al.* (1989), Round (1988), Smythies (1986).

145. Malabar Parakeet
Psittacula columboides

French: Perruche de Malabar **German:** Taubensittich **Spanish:** Cotorra de Malabar
Other common names: Blue-winged Parakeet

Taxonomy. *Palaeornis columboides* Vigors, 1830, Aneichardi, Travancore. Monotypic.
Distribution. Western Ghats, SW India.

Descriptive notes. 36-38 cm. Upper mandible red with yellowish tip, lower dull brownish; area from bill to around eye bluish green; rest of head warm greyish, with complete black collar bordered turquoise below, shading immediately into grey of upper body; wing-coverts green edged buff, outer wing-coverts and primaries deep blue; belly and thighs light green, rump light turquoise, tail deep blue centrally, green laterally, marginally tipped yellow. Female lacks turquoise in neck-ring, with mantle and breast pale green, black bill. Immature replaces all grey with green.
Habitat. Tropical evergreen and moist deciduous forest, secondary growth, abandoned plantations, and adjacent cultivated clearings, from low-lands to 1600 m, but chiefly at 450-1000 m.
Food and Feeding. Grain, seeds and fruits especially of figs (*Ficus*), also buds, petals and nectar, notably *Erythrina* and *Grevillea* plants. A crop pest on *Sorghum*, other cereals, vetches *Dolichos* and orchard fruit.
Breeding. Dec-Mar. Nest in hole in tree 6-30 m from ground (high trees preferred), with ironwood (*Mesua ferrea*) and *Grewia tilifolia* particularly favoured. Usually 4-5 eggs (average clutch 4-63); incubation 23 days (27 in captivity) by both sexes, but mostly by female; female tends young except at end of nestling period, when male does so; nestling period 32 days. Seemingly high breeding success.
Movements. Resident, but some nomadism in response to food availability occurs.
Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Common throughout core of range. Clearance of forest in parts of the Western Ghats must have reduced range, but not to a degree where serious risk exists.

Bibliography. Ali (1996), Ali & Ripley (1981), Chakravarthy & Purna Chandra Tejasvi (1992), Chauhan (1996), Curr (1971), Jayewardene (1963), Percival (1910), Ripley (1982), Saha & Dasgupta (1992), Tavistock (1929b), Vriends (1979), Wheatley (1996).

146. Emerald-collared Parakeet
Psittacula calthropae

French: Perruche de Layard **German:** Blauschwanzsittich **Spanish:** Cotorra de Ceilán
Other common names: Layard's/Sri Lankan Parakeet

Taxonomy. *Palaeornis Calthropae* [sic] Blyth, 1849, Sri Lanka. Species name originally based on maiden name, Calthrop, of E. L. Layard's wife, so justifiably emended; sometimes erroneously listed as *calthropae*. Monotypic.
Distribution. Sri Lanka.

Descriptive notes. 29-31 cm. Upper mandible red with yellowish tip, lower dull brownish; forehead and area round eye to lower mandible soft green, rest of head bluish grey shading to black area on chin and sides of neck, this in turn bordered by broad emerald collar extending around neck and onto underparts: mantle, back and rump bluish grey; wings dull green, greyish on lesser and yellowish on median wing-coverts; tail deep grey-blue tipped yellow. Female has greyish black bill. Immature replaces grey with green.
Habitat. Hill forests and clearings ranging up to 2000 m, penetrating to sea-level only in parts

of wet zone in SW of island.
Food and Feeding. Fruits of *Macaranga tomentosa*, wild fig and wild cinnamon, flowers of "bomba tree", buds and nectar, with less granivory owing to more strictly arboreal habits.
Breeding. Jan-May, and often again in Jul-Sept. Nest usually high (10-25 m) in hollow limb or hole in tree, including *Pterocarpus*, *Syzygium* and *Terminalia*. Eggs 2-4; in captivity, incubation c. 3 weeks, nestling period 7 weeks.
Movements. Apparently sedentary, but altitudinal movements may occur.
Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. This bird has suffered from the conversion of forest to plantation, and in some areas has disappeared completely. Still fairly common in Sinharaja National Heritage Wilderness Area, and in forest around Kitulgala.

147. Derbyan Parakeet
Psittacula derbiana

French: Perruche de Derby **German:** Chinasittich **Spanish:** Cotorra de Derby
Other common names: (Lord) Derby's Parakeet

Taxonomy. *Palaeornis Derbianus* Fraser, 1852, no locality, cage-bird. Monotypic.
Distribution. SW China, SE Tibet and NE Assam.

Descriptive notes. 46-50 cm. Bill red above tipped yellow, black below; narrow black frontal band stretching back to eye set in light turquoise on forehead and around eye, shading to purple on rest of head except for broad black bar extending from lower mandible below ear-coverts; nape and upperparts green with yellowish wash on median wing-coverts; underparts purple except for thighs and vent; tail bluish centrally, green laterally, yellowish below. Female lacks turquoise on head and has all-black bill. Immature duller, with green head.
Habitat. Coniferous and mixed *Pinus-Quercus* forests, *Rhododendron* alpine thick-

ets and cultivated valleys up to 4000 m.
Food and Feeding. Seeds of *Pinus tabulaeformis*, poplar catkins, barley and orchard fruit, notably peaches, and often destructive to ripening crops including maize.
Breeding. Jun in SE Tibet. Nest in hole in tree, often *Populus ciliata*; reportedly also in "sand nests", presumably in high riverbanks.
Movements. Summer visitor to NE India, May-Sept, but apparently resident in SE Tibet, persisting as high as 3300 m in winter.
Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. Apparently fairly common within its relatively little visited range, recorded as usually occurring in large flocks.
Bibliography. Ali & Ripley (1981), Anon. (1994d), Baumgärtner (1997a), Cheng Tsohsin (1987), Échécopar & Hüe (1978), Ezra (1933), King (1983), Ludlow (1944, 1951), Meyer de Schauensee (1984), Norris (1954), Payne (1956), Ripley (1982), Stoner (1952), Tavistock (1929a), Vaurie (1965), Vit (1996b), Wheatley (1996).

148. Red-breasted Parakeet
Psittacula alexandri

French: Perruche à moustaches **German:** Bartsittich **Spanish:** Cotorra Pechirroja
Other common names: Rose-breasted/Moustached Parakeet

Taxonomy. *Psittacus alexandri* Linnaeus, 1758, China, Bengal, Ethiopia = Java. Closest relatives probably *P. derbiana* and *P. caniceps*, despite size differences. Eight subspecies recognized.
Subspecies and Distribution.
P. a. fasciata (P. L. S. Müller, 1776) - N India E through Nepal, Bangladesh, Myanmar, Thailand, extreme N Peninsular Malaysia and Indochina to S China and Hainan.

P. a. abbotti (Oberholser, 1919) - Andaman Is.
P. a. cala (Oberholser, 1912) - Simeulue I.
P. a. major (Richmond, 1902) - Lasia and Babi Is.
P. a. perionca (Oberholser, 1912) - Nias I.
P. a. alexandri (Linnaeus, 1758) - Java, Bali and extreme S Borneo.
P. a. kangeanensis Hoogerwerf, 1962 - Kangean Is.
P. a. dammermani Chasen & Kloss, 1932 - Karimunjawa Is.

Introduced to Singapore where breeding regular since mid-1980's, but subspecies involved as yet undetermined. Population of Borneo commonly considered introduced, but this is not necessarily correct.

Descriptive notes. 33-38 cm; 133-168 g. Bill red, tipped yellow; head pale blue-grey with thin black line from cere to eye, black chin and lower cheeks; underparts pink from throat to mid-belly, then pale green; sides of neck, nape and upperparts green, with yellowish wash on median wing-coverts. Female has duller pink underparts. Immature has green head and underparts. Race *kangeanensis* has less blue in head, yellowish wing-patch; *dammermani* larger; *fasciata* has blue tinge to head, darker pink breast with light blue wash, lower mandible blackish; *abbotti* like *fasciata* but larger and paler; *cala* like *abbotti* but less blue suffusion

in pink; *major* like *cala* but larger; *perionca* like *major* but slightly smaller, belly and vent brighter.

Habitat. Moist deciduous forest, secondary growth, mangroves, teak and coconut plantations, woodland adjacent cultivation and villages, in foothill and lowland areas, generally avoiding dense evergreen closed-canopy forest.

Food and Feeding. Little specific information; nectar and flowers of *Salmalia*, *Bombax*, *Butea*, *Parkia speciosa* and *Erythrina variegata*, seeds of *Albizia*, chestnuts (*Castanea*), fruits of *Ficus*, leaf buds of teak, rice and other grain recorded.

Breeding. Generally Dec-Apr in continental Asia, including Singapore; every month but Apr on Java. Nest in hollow limb or hole in tree, often with several pairs occupying adjacent trees. Eggs 3-4; in captivity, incubation c. 28 days, and nestling period c. 50 days.

Movements. Generally sedentary but with local irregular movements sometimes coinciding with food supply changes or, in N of range, periods of cold weather.

Status and Conservation. Not globally threatened. CITES II. In continental Asia the species is generally common throughout its range, also on the Andamans where at least formerly considered the commonest bird of the islands, and may do serious local damage to crops; also considered the commonest parrot in S Indochina around 1930. However, there has been a considerable decline in numbers and range within Thailand and Laos in recent years and the species is probably uncommon in China. Moreover, with the exception of Nias (where it was common as a cage-bird in 1990), there appear to be no recent reports from many of the small Indonesian islands where it occurs (it was under potential threat from trade on Simeulue, 1981), it is only very locally common in Kalimantan, and on Java and Bali it has suffered declines and local extinctions in response to the local cagebird trade. International trade is high: a total of 66,601 live birds were recorded in the period 1987-1992, chiefly coming from Vietnam (42%), Indonesia (27%) and India (15%), and chiefly going to Singapore (28%), Japan (21%) and USA (12%).

Bibliography. Abdulali (1964), Albion & Albion (1991), Ali (1996), Ali & Ripley (1981), Ali *et al.* (1996), Cheng Tsohsin (1963, 1987), Deignan (1945, 1963), Delacour & Jabouille (1931), Dymond (1994), Étchécopar & Hue (1978), Genuise (1993), Harvey (1990), Hellebrekers & Hoogerwerf (1967), Holmes (1994a), Holmes & Burton (1987), Hoogerwerf (1949, 1962), Inskipp & Inskipp (1991), Lekagul & Round (1991), Lever (1987), MacKinnon (1988), MacKinnon & Philipps (1993), Majumdar *et al.* (1992), van Marle & Voous (1988), Medway & Wells (1976), Ripley (1944, 1982), Round (1988), Sane & Kannan (1985), Smythies (1981, 1986), Stepanyan (1995), Tikader (1984), Vane (1953), Vriends (1979).

149. Nicobar Parakeet

Psittacula caniceps

French: Perruche des Nicobar **German:** Graukopfsittich **Spanish:** Cotorra de Nicobar
Other common names: Blyth's (Nicobar) Parakeet

Taxonomy. *Paleornis caniceps* Blyth, 1846. Nicobars. Monotypic.

Distribution. Nicobar Is, on Great and Little Nicobar, Montschall and Kondul.

Descriptive notes. 56-61 cm; 224 g. Bill red above, black below; head pale grey with black frontal band extending to eye and broad black band from lower mandible and chin to sides of neck, sometimes extending as very faint pale brown collar round hindneck; rest of body grass green, tail tinged yellowish grey and tipped yellowish. Female has head strongly tinted blue, upper mandible black. Immature undescribed.

Habitat. Tall forest.

Food and Feeding. Ripe fruits of *Pandanus* extensively used.

Breeding. No information.

Movements. Sedentary.

Status and Conservation. Not globally threatened, CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. Apparently common; many birds are caught for the local cagebird trade, but much habitat remains on the islands.

Bibliography. Abdulali (1964, 1967, 1978), Ali & Ripley (1981), Collar & Andrew (1988), Collar *et al.* (1994), Harrison & Holyoak (1970), Ripley (1982), Tikader (1984), Wheatley (1996).

150. Long-tailed Parakeet

Psittacula longicauda

French: Perruche à longs brins **German:** Langschwanzsittich

Spanish: Cotorra Colilarga

Other common names: Pink-checked/Red-cheeked Parakeet

Taxonomy. *Psittacus longicauda* Boddaert, 1783, Malacca.

Five subspecies recognized.

Subspecies and Distribution.

P. l. tyleri (Hume, 1874) - Andaman Is and nearby Cocos Is.

P. l. nicobarica (Gould, 1857) - Nicobar Is.

P. l. longicauda (Boddaert, 1783) - S Peninsular Malaysia and Singapore through Sumatra, Nias and Bangka to Anambas Is and Borneo.

P. l. modesta (Fraser, 1845) - Enggano I (off SW Sumatra).

P. l. defontainei Chasen, 1934 - Natuna Is (off W Borneo).

Descriptive notes. 40-48 cm; 168-196 g. Upper mandible red, lower blackish red; crown and area above line from cere to eye dark green; area from lower mandible and chin tapering onto lower sides of neck black; rest of head and nape rose pink, shading to pale yellowish green on mantle and upper back, pale bluish on lower back, green on uppertail-coverts; undersides greenish yellow shading slightly darker on belly; wings green with dull blue on primary coverts and primaries; tail deep blue centrally, outer feathers green. Female replaces rose pink on head with dull orange-red, with blue wash on ear-coverts; bill

all brownish. Immature mainly green, some orange-red tinge on sides of head. Race *defontainei* has deeper red on head, yellowish crown; *modesta* crown appears brownish, as feathers dull red mixed with green, duller brownish in female; *tyleri* crown, nape, mantle and upper back yellowish green, rump and lower back green; *nicobarica* bright green crown with yellowish green nape. Last three races larger than first two, *nicobarica* largest.

Habitat. An extreme lowland species, ranging up to 300 m but preferring areas in coastal regions, including mangroves, swamp forest (including peat swamp forest), rain forest edge, partly cleared land, oil-palm plantations, coconut groves.

Food and Feeding. Specific items include outer covering of betel nuts *Areca catechu*, papaya *Carica papaya*, ripe *Pandanus* fruit, fruits of kapor *Dryobalanops*, *Dillenia speciosa* and *Sonneratia alba*, flowers of *Acacia* and *Bombax*, seeds of *Macaranga*, *Ixonanthes*, *Vitex pybescens*, *Lagerstroemia*, *Dipterocarpus crinitus*. Can be pest in oil-palms, plucking ripe fruits to eat the soft mesocarp.

Breeding. Generally Dec-May in Malaysia; Jun in Kalimantan; Oct in Sumatra; Feb-Apr in Andamans and Nicobars. Nest in hole in tree, in one case adjacent to grass swamp, in another 10 m up in peat swamp forest; on Andamans usually in *Pterocarpus marsupium*, 4-8 m up. Breeds colonially, with multiple pairs (one count of 16) using neighbouring holes in particular tree or group of trees; 6-20 m up, but on Sumatra once 45 m up in dead limb of *Koompassia*. Eggs 2-3; in captivity, incubation 24 days.

Movements. Poorly understood fluctuations in numbers occur throughout range. In some parts of range, large flocks may build up or suddenly arrive in an area, then the species may be absent for several years. Certain statements based on single season or year's observations may not be reliable. In Membakut area of Sabah, however, birds reported to congregate in large flocks. Sept-Apr. These observations are consistent with the species being nomadic and/or trap-lining around food-resources over huge communal home ranges. Although once considered on passage only, Singapore, now judged resident although birds commute across Johor Straits.

Status and Conservation. Not globally threatened. CITES II. Very common and widespread in S Kalimantan; locally common on Sumatra, where however formerly abundant, decline being linked to loss of breeding sites in primary forest; locally common in Peninsular Malaysia, where its capacity to survive is linked to its ability to forage outside rain forest and to nest communally. Occurs in very large numbers in some areas, Brunei. Common, Andamans and Nicobars. International trade was relatively slight, 1981-1985, but in the period 1986-1990 an average 2143 birds were exported annually, mostly from Malaysia. Anticipated pest status in oil-palm plantations has not been fulfilled, probably because of inability of birds to breed in such habitat.

Bibliography. Abdulali (1964, 1967, 1978), Ali & Ripley (1981), Andrew (1992), Anon. 151. Vernal Hanging-parrot

Loriculus vernalis

French: Coryllis vernal **German:** Frühlingspapageichen **Spanish:** Lorículo Vernal
Other common names: Indian Hanging-parrot/Lorikeet

Taxonomy. *Psittacus vernalis* Sparrman, 1787, Cachar. Forms a superspecies with *L. beryllinus*. Birds of S India formerly placed in race *rubropygialis*, on basis of darker coloration and duller red rump, but these differences subsequently put down to individual variation and/or wear. Monotypic.
Distribution. SW, S & E India and E Nepal through S China and SE Asia to Indochina, except Malay Peninsula; Andamans, Nicobars and Mergui Archipelago.

Descriptive notes. 13 cm. Bill orangish red; plumage generally green, with yellow tone to underparts; pale blue patch on throat; rump and uppertail-coverts red; underside of flight-feathers and tail blue; legs orange. Female paler, with blue on throat reduced or lacking. Immature has dull greyish wash on face and cheeks, rump with green feathers.
Habitat. Evergreen forest, moist and dry deciduous woodlands, secondary growth, abandoned cultivated land, bamboo thickets, forest edge, orchards, tall scrub and beach-strand woodland particularly with mature casuarinas; up to 1800 m in Nilgiris.

Food and Feeding. Soft pulp of fruits and berries, chiefly figs (*Ficus*), largely supplemented by flower nectar, notably *Erythrina*, eucalypts, mistletoes and *Salmalia malabarica*; also seeds of *Casuarina*, *Tectona grandis* and bamboo. Can damage local crops of guavas (*Psidium*) and loquats (*Eriobotrya japonica*).

Breeding. Jan-Apr; in Andamans chiefly Jan-Feb. Nest in natural hollow in rotten tree stem or branch. Eggs 2-4; in captivity, incubation lasts 22 days, nestling period around 5 weeks.

Movements. In India subject to poorly understood local migrations, being a rains visitor in certain parts and a winter visitor in others.

Status and Conservation. Not globally threatened. CITES II. Very common on Andaman and Nicobar Is, reasonably so in S Thailand (common in Khao Yai National Park in NC). Common in Cambodia, around 1930. Extremely rare in China.

Bibliography. Abdulali (1964), Ali (1996), Ali & Ripley (1981), Ali *et al.* (1996), Buckley (1968), Chakravarty & Purna Chandra Tejasvi (1992), Cheng Tsohsin (1987), Deignan (1945), Delacour & Jabouille (1931), Donahue (1962), Fleming & Traylor (1968), Harvey (1990), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Lekagul & Round (1991), Medway & Wells (1976), Neelakantan (1973), Ripley (1982), Saha & Dasgupta (1992), Smythies (1986), Stepanyan (1995), Tikader (1984).

152. Ceylon Hanging-parrot

Loriculus beryllinus

French: Coryllis de Ceylan **German:** Ceylonpapageichen **Spanish:** Lorículo de Ceilán
Other common names: Sinhalese/Sri Lankan Hanging-parrot, Ceylon Lorikeet

Taxonomy. *Psittacus beryllinus* J. R. Forster, 1781, Sri Lanka. Forms a superspecies with *L. vernalis*. Monotypic.
Distribution. Sri Lanka.

Descriptive notes. 13-14 cm. Bill orangish red; entire crown red, shading on nape to golden yellow extending onto mantle and back; face yellowish green, extending in thin line above red-ringed eye and down onto sides of neck and underparts; chin and throat smudged blue; wings and tail green; rump and uppertail-coverts red; legs orange. Female has less blue throat. Immature generally lacks head and mantle colour, and may fledge with face and forehead naked.

Habitat. Wooded country, groves, plantations, coconut groves and gardens up to 1250 m, reaching 1600 m in NE monsoon.

Food and Feeding. Nectar of *Erythrina*, *Salmalia* and introduced eucalypts; seeds of *Casuarina*; fruit of "jambu" (presumably *Eugenia*); flowers and fruit of cultivated bananas.

Breeding. Jan-Sept, chiefly Mar-May. Nest in hollow in tree-stump or branch. Eggs 2-3.

Movements. Some upward altitudinal displacement appears to occur in the NE monsoon.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Widespread, and most plentiful in the SW of the island and almost absent from arid N.

Bibliography. Ali & Ripley (1981), Bloom (1960), Henry (1962, 1971), Kotagama & Fernando (1994), Legge (1880), Phillips (1978), Ripley (1982), Wait (1925), Wijesinghe (1994).

153. Philippine Hanging-parrot

Loriculus philippensis

French: Coryllis des Philippines **German:** Philippinenpapageichen **Spanish:** Lorículo Filipino

Other common names: Colasisi; Black-billed Hanging-parrot (*bonapartei*)

Taxonomy. *Psittacus philippensis* P. L. S. Müller, 1776, Philippines = Luzon. Race *bonapartei* sometimes considered worthy of species status, based on black bill and grey legs, although these colours may be variable. Proposed race *panayensis* is synonym of *regulus*; *salvadorii* is synonym of *apicalis*. Ten subspecies currently recognized.

Subspecies and Distribution.

L. p. philippensis (P. L. S. Müller, 1776) - Luzon and adjacent islands, Philippines.
L. p. mindorensis Steere, 1890 - Mindoro.
L. p. bournsi McGregor, 1905 - Sibuyan.
L. p. regulus Souancé, 1856 - Tablas, Ticao, Masbate, Panay, Guimaras, Negros; probably this race on Romblon.
L. p. chrysonotus P. L. Sclater, 1872 - Cebu.
L. p. worcesteri Steere, 1890 - Samar, Leyte, Bohol.
L. p. siquijorensis Steere, 1890 - Siquijor.
L. p. apicalis Souancé, 1856 - Mindanao and adjacent islands.
L. p. dohertyi Hartert, 1906 - Basilan.
L. p. bonapartei Souancé, 1856 - Sulu Archipelago.

Descriptive notes. 14 cm; 31-40 g. Green, more yellowish on undersides; bill orange-red, forehead to mid-crown red bordered by narrow yellow line; golden orange patch on nape; large red patch on throat and upper breast; rump and uppertail-coverts red, sides of rump pale blue; underside of wings and tail pale blue; legs orange. Female lacks red on throat, and only small red patch on forehead; pale blue area around base of bill. Immature similar with reduced red on crown. Race *mindorensis* lacks yellowish tones around crown, nape spot reduced or absent; *bournsi* with reduced red on crown with small yellow patch; *regulus* entire hindcrown golden yellow; *chrysonotus* hindcrown to upper back golden yellow, with orange collar; *worcesteri* entire crown red, orangish yellow on nape, mantle faintly tinged orange; *apicalis* similar but mantle washed golden yellow; *dohertyi* similar but mantle more orange, breast spot larger; *siquijorensis* hindcrown and nape green, smaller throat patch; *bonapartei* with orange hindcrown and nape, bill black, legs dull greyish.

Habitat. Forest, forest edge, secondary growth, orchards, coconut groves, bushy areas, and bamboo clumps, generally in lowlands, scarcer above 1250 m.
Food and Feeding. Nectar and blossoms, e.g. of coconuts, and soft fruit such as *Ficus*.
Breeding. Mar-May. Nest recorded in hole 12 m up in dead tree bordering a forest clearing. In captivity: 3 eggs; incubation lasting 20 days; nestling period c. 5 weeks.

Movements. No information.
Status and Conservation. Not globally threatened. CITES II. Common throughout most of range; even race *bournsi* was recently found common at three sites on Sibuyan, being reported as a pest to ripening fruit crops. However, race *regulus* judged to be in immediate danger of extinction, owing to the high degree of forest loss throughout its range; race *mindorensis* is considered near-threatened; race *siquijorensis* may well now be extinct; and race *chrysonotus*, although long regarded as extinct, survives in tiny numbers at one site in C Cebu (Central Cebu National Park), the island's last remaining small patch of forest which continues to be degraded, despite theoretical protected status. The species is heavily traded within the Philippines, and apart from habitat loss the rarer subspecies may now face or in the past have suffered from trade pressures; the population on Bohol, which may represent an undescribed subspecies, is heavily trapped there and evidently already very scarce.

Bibliography. Alonzo-Pascolan (1992), Amadon & Jewett (1946), Anon. (1993), Brooks, Dutton *et al.* (1996), Brooks, Evans *et al.* (1992), Burr (1981), Danielsen *et al.* (1994), Delacour & Mayr (1946), Dickinson *et al.* (1991), DuPont (1971), DuPont & Rabor (1973a, 1973b), Dutton *et al.* (1992), Evans, Dutton & Brooks (1993), Evans, Magsalay *et al.* (1993), Gilliard (1950b), Goodman *et al.* (1995), Hachisuka (1934), Harrison & Holyoak (1970), Inskipp *et al.* (1996), Magsalay (1993), McGregor (1909-1910), Parkes & Dickinson (1991), Potter (1953), Rabor (1955, 1977), Rand (1959), Rand & Rabor (1960), Ripley & Rabor (1958), Salvadori (1891a), Sargeant (1992), Spenkelink-van Schaik (1980a).

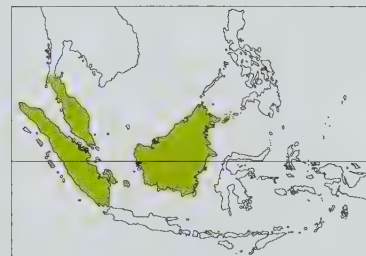

154. Blue-topped Hanging-parrot

Loriculus galgulus

French: Coryllis à tête bleue **German:** Blaukrönchen **Spanish:** Lorículo Coroniazul
Other common names: Blue-crowned/Malaysian Hanging-parrot, Malay Lorikeet

Taxonomy. *Psittacus Galgulus* Linnaeus, 1758, India; error = Malacca. Monotypic.

Distribution. S Thailand, W Malaysia, Singapore, Sumatra and associated islands, and Borneo and associated islands. Also W Java, where presumably introduced.

Descriptive notes. 12 cm; 22-35 g. Bright emerald, more yellowish on underparts; bill black; middle of crown blackish blue; throat patch red; triangular patch on mantle golden yellow; lower back yellow; rump and uppertail-coverts red; legs buff-orange. Female lacks red throat patch and yellow on lower back, much smaller crown patch. Immature duller with greatly reduced red and yellow.

Habitat. Forest and forest edge, secondary growth, peat swamp and riverine forest, bamboo patches, landward edge of mangroves, beach-strand woodland especially with casuarinas, wooded gardens, coconut groves, plantations, up to 1300 m, exceptionally to 2000 m, in Indonesia up to 500 m; possibly more abundant in selectively logged than primary forest.

On following pages: 155. Maroon-rumped Hanging-parrot (*Loriculus stigmatus*); 156. Sula Hanging-parrot (*Loriculus sclateri*); 157. Moluccan Hanging-parrot (*Loriculus amabilis*); 158. Sangihe Hanging-parrot (*Loriculus catamene*); 159. Orange-fronted Hanging-parrot (*Loriculus aurantiifrons*); 160. Green-fronted Hanging-parrot (*Loriculus tener*); 161. Green Hanging-parrot (*Loriculus exilis*); 162. Yellow-throated Hanging-parrot (*Loriculus pusillus*); 163. Flores Hanging-parrot (*Loriculus flosculus*).

Food and Feeding. Few specific records: fruit of various figs including *Ficus caulocarpa*, *F. virens*, *F. delosyae*, *F. pisocarpa*, *F. kerkenhovenii*, *F. crassiramea* and *F. stupenda*, also flowers of *Erythrina* and durian *Durio zibethinus*, and mesocarp of oil-palm fruits.

Breeding. Jan-Aug, possibly later, in Sumatra. Nest in hollow in living or dead tree, including dead *Oncosperma* palms and rubber trees in disturbed forest, 8-12 m up. Eggs 3; in captivity, nestling period c. 5 weeks.

Movements. Birds may move about widely, even ranging between adjacent islands. May trapline around a large communal home range or is truly nomadic.

Status and Conservation. Not globally threatened. CITES II. Very common and widespread throughout range except Singapore, where now very uncommon. Very popular as cage-birds. Malaysia, which exported 38,381 birds in the period 1985-1990; however, this and trade pressure elsewhere do not appear to constitute a significant impact on populations. In agricultural lowlands, requires patches of tall, semi-natural woodland for breeding sites.

Bibliography. Andrew (1992), Anon. (1993), van Balen & Lewis (1991), Barnicoat (1992), Bloom (1960), Buckley (1968), Chasen & Hoogerwerf (1941), Duckworth & Kelsh (1988), Gibson-Hill (1949), Gore (1968), Hails & Jarvis (1987), Holmes (1994b), Holmes & Burton (1987), Holmes & Nash (1991), Lekagul & Round (1991), MacKinnon & Philipps (1993), Madoc (1976), Mann (1987), van Marle & Voous (1988), Medway & Wells (1976), Nash & Nash (1988), Norgaard-Olesen (1968), Reinschmidt (1997), Silvius & Verheugt (1986), Smythies (1981), Wilkinson, Dutton & Sheldon (1991).

155. Maroon-rumped Hanging-parrot

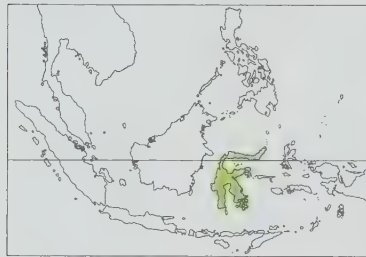

Loriculus stigmatus

French: Coryllis des Célèbes **German:** Rotplättchen **Spanish:** Lorículo de Célebes
Other common names: (Large) Sulawesi/Black-billed Hanging-parrot

Taxonomy. *Psittacus* (*Psittacula*) *stigmatus* S. Müller, 1843, Sulawesi.

Forms a superspecies with *L. sclateri*, *L. amabilis*, *L. catamene*, *L. aurantiifrons* and *L. tener*. Proposed races *croconotus* and *quadricolor* based on slight, probably individual variation. Monotypic.

Distribution. Sulawesi and adjacent islands.

Descriptive notes. 15 cm. Generally green, more yellowish on underparts; bill black; forehead to front of eye and mid-crown red; nape and mantle tinged orange; throat patch red; edge of wing red; rump and uppertail-coverts maroon; legs orange. Female lacks red on crown; throat patch often reduced. Immature similar, with throat patch yellowish and wing edge yellowish, bill and legs duller.

Habitat. Inhabits primary and tall secondary lowland and hill forest, forest edge, lightly wooded cultivation and scrub, mangrove and coconut plantations, occurring from sea-level to 1000 m.

Food and Feeding. Nectar from blossoms of *Eugenia*, flowers of *Ceiba pentandra* and soft fruits such as figs (*Ficus*) and *Tamarindus*.

Breeding. Jan-Feb, Apr-Jun and Aug. Nest in hole in bamboo or broken tree-trunk. Two young recorded in nest.

Movements. Apparently nomadic or migratory: in S Sulawesi recorded as most numerous, Oct-Dec.

Status and Conservation. Not globally threatened. CITES II. Considered widespread and common throughout range, occurring in wide variety of habitats including several extensively modified by humans.

Bibliography. Andrew (1992), Baltzer (1990), van Bemmelen & Voous (1951), Coates & Bishop (1997), Coomans de Ruiter (1951), Coomans de Ruiter & Maurenbrecher (1948), Fraser & Henson (1996), Holmes & Philipps (1996), McKean (1982), Rozendaal & Dekker (1989), Stresemann (1940), Watling (1983), White & Bruce (1986).

156. Sula Hanging-parrot

Loriculus sclateri

French: Coryllis des Sula **German:** Sulapapageichen **Spanish:** Lorículo de las Sula

Taxonomy. *Loriculus sclateri* Wallace, 1863, Sula Islands.

Forms part of the *L. stigmatus* superspecies. Sometimes treated as conspecific with *L. amabilis* and *L. catamene*. Proposed race *ruber* from Banggai based on character present in at least some *L. amabilis*, probably age-related. Monotypic.

Distribution. Sula and Banggai Is (off EC Sulawesi).

Descriptive notes. 14 cm. Considerably larger than *L. amabilis* with no red on head and a large orange patch, often with large red centre, on lower mantle and upper back. Female similar. Immature has duller red areas, and orange area on back dull and ill-defined, with little or no red.

Habitat. Primary and secondary forest and adjacent partially cleared lands.

Food and Feeding. No information.

Breeding. No information.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range"

species. Reported to be common throughout both island groups.

Bibliography. Andrew (1992), Bishop (1992), Coates & Bishop (1997), Davidson *et al.* (1995), Sujatnika *et al.* (1995), White & Bruce (1986).

157. Moluccan Hanging-parrot

Loriculus amabilis

French: Coryllis des Moluques **German:** Zierpapageichen **Spanish:** Lorículo Amable

Taxonomy. *Loriculus amabilis* Wallace, 1862, Halmahera.

Forms part of the *L. stigmatus* superspecies. Sometimes treated as conspecific with *L. sclateri* and *L. catamene*. Monotypic.

Distribution. Halmahera and Bacan in N Moluccas.

Descriptive notes. 11 cm. Emerald green, slightly darker on upperparts and wings; bill black; forehead to mid-crown red; throat patch, edge of wing, and rump and uppertail-coverts red; legs orange. Female has green crown and less red on throat, vague orange bloom on mantle. Immature has yellowish throat patch and forewing.

Habitat. Primary and secondary forest areas, selectively logged forest, coastal *Casuarina* trees, tall mangroves and edges of agricultural clearings, occasionally coconut groves. Generally found in lowlands, but this may simply be because most of the preferred secondary

habitat is in the lowlands, not a genuine altitude preference.

Food and Feeding. Birds have been seen foraging in the crowns of tall flowering and fruiting *Erythrina* and *Casuarina* trees, *Rhizophora* mangroves and coconut palms.

Breeding. No information.

Movements. Known to make diurnal movements over long distances.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Overall, moderately common; rare in primary forest, commoner in secondary forest.

Bibliography. Andrew (1992), Coates & Bishop (1997), Inskipp *et al.* (1996), Lambert & Young (1989), Sujatnika *et al.* (1995), White & Bruce (1986).

158. Sangihe Hanging-parrot

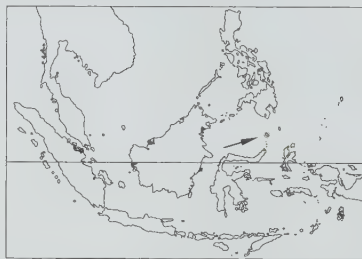

Loriculus catamene

French: Coryllis des Sangi **German:** Rotsteißpapageichen **Spanish:** Lorículo de la Sangihe

Taxonomy. *Loriculus catamene* Schlegel, 1873, Great Sangihe Island.

Forms part of the *L. stigmatus* superspecies. Sometimes treated as conspecific with *L. sclateri* and *L. amabilis*. Monotypic.

Distribution. Sangihe I, NE of Sulawesi.

Descriptive notes. 12 cm. Similar to *L. amabilis* but edge of forewing yellowish green, undertail-coverts orange-red edged green, tail tipped red; lacks red on forecrown.

Habitat. Primary and secondary forest, mixed orchards, coconut groves, in lowlands and hills, from sea-level up to 900 m.

Food and Feeding. No information.

Breeding. No information.

Movements. No information.

Status and Conservation. **ENDANGERED.** CITES II. A BirdLife "restricted-range" species. This bird has suffered from the extensive clearance of original vegetation on its

single small island, but fears of its extinction in the 1980's have happily been allayed by fieldwork in 1995 and 1996 which has found it common in some previously undocumented forested areas.

Bibliography. Andrew (1992), Coates & Bishop (1997), Collar & Andrew (1988), Collar *et al.* (1994), Inskipp *et al.* (1996), Riley (1997), Sujatnika & Jepson (1995), Sujatnika *et al.* (1995), White & Bruce (1986), Whitten, Bishop *et al.* (1987).

159. Orange-fronted Hanging-parrot

Loriculus aurantiifrons

French: Coryllis à front orange **German:** Goldstirnpapageichen **Spanish:** Lorículo Papú
Other common names: Papuan Hanging-parrot, Bat Lorikeet

Taxonomy. *Loriculus aurantiifrons* Schlegel, 1873, Misool.

Forms part of the *L. stigmatus* superspecies. Often considered to include *L. tener*. Three subspecies currently recognized.

Subspecies and Distribution.

L. a. aurantiifrons Schlegel, 1873 - Misool in W Papuan Is.

L. a. batavorum Stresemann, 1913 - Waigeo in W Papuan Is, and W & NW New Guinea.

L. a. meeki Hartert, 1895 - E New Guinea, and islands of Fergusson, Goodenough and Karkar.

Descriptive notes. 10 cm; 13-16 g. Green, more yellowish on underparts; bill black; forehead golden yellow; throat patch red; rump and uppertail-coverts red, with yellow sides to rump; undersides of wings greenish blue; legs dull yellowish. Female has forehead bluish green, smaller red throat patch. Immature like female without red throat patch. Race *batavorum* has less yellow on forehead; *meeki* supposedly but doubtfully larger, less yellow on forecrown.

Habitat. Lowland forest and secondary growth, noted visiting casuarinas, pines and palms; commonly up to 300 m, more rarely

up to 1200 m or even 1600 m.

Food and Feeding. Nectar, buds and blossoms, possibly also seeds and lerps. White paste in stomach was apparently "flower sap".

Breeding. Sept-Oct. Nest in small hollow in narrow tree; hole in an arboreal termitarium seen visited, but possibly only for roosting. Eggs reportedly four.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Regarded as commoner on Karkar than on mainland, but this may in part reflect greater observational difficulties, or else the species prefers more disturbed areas, in which it has been found to be common; has been reported as rare in primary habitats.

Bibliography. Andrew (1992), Anon. (1994a), Beehier *et al.* (1986), Bell (1970d), Coates (1985), Diamond (1972a), Diamond & LeCroy (1979), Gregory (1995a, 1995b), Mayr & Rand (1937), Mees (1965), Rand (1942b), Rand & Gilliard (1967), Schodde & Hitchcock (1968), Sims (1956).

160. Green-fronted Hanging-parrot

Loriculus tener

French: Coryllis des Bismarck

Spanish: Loriculo de las Bismarck

German: Bismarckpapageichen

Other common names: Bismarck Hanging-parrot

Taxonomy. *Loriculus tener* P. L. Selater, 1877, Duke of York Island.

Forms part of the *L. stigmatus* superspecies. Commonly treated as a race of *L. aurantiifrons*, but plumage distinctly different in several features, suggesting species status more appropriate. Monotypic.

Distribution. Bismarck Archipelago.

Descriptive notes. 10 cm; 12 g. Similar to *L. aurantiifrons* but forehead green, throat patch orange-red, rump and uppertail-coverts yellow; underside of tail pale blue.

Habitat. Forest and secondary growth along coasts.

Food and Feeding. No information.

Breeding. No information.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. Fairly common but perhaps seasonally or locally hard to find.

Bibliography. Coates (1985), Collar *et al.* (1994), Dahl (1986), Finch & McKean (1987), Gilliard & LeCroy (1967a).

161. Green Hanging-parrot

Loriculus exilis

French: Coryllis vert

German: Däumlingspapageichen

Spanish: Loriculo Exiguo

Other common names: Red-billed/Pygmy/Small Sulawesi Hanging-parrot

Taxonomy. *Loriculus exilis* Schlegel, 1866, Tulabulo, Sulawesi.

Forms a superspecies with *L. pusillus* and *L. flosculus*, and sometimes considered conspecific with latter. Monotypic.

Distribution. Sulawesi.

Descriptive notes. 10-11 cm. Green, more yellowish on underparts; bill red; thin red spot on throat, bordered bluish below; rump and uppertail-coverts red; legs orange. Female has red throat patch reduced or absent. Immature has no throat patch, yellowish bill and legs.

Habitat. Hill and lowland forest, occasionally mangroves and trees in open country, from sea-level to 1000 m.

Food and Feeding. Figs (*Ficus*), nectar and blossoms.

Breeding. Feb and Aug. Nest in hole in dead palm.

Movements. Probably nomadic, following the flowering of trees; in May 1871, after several months with only a single observation, large flocks appeared at the seaboard in extreme N Sulawesi, frequenting mangroves.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Overlooked or decidedly local, generally in small numbers. Uncommon to rare, Dumoga-Bone National Park. Generally low numbers in trade, but 2131 reported by Indonesia in 1991; zero quotas were set in 1994 and 1995.

Bibliography. Andrew (1992), Andrew & Holmes (1990), Coates & Bishop (1997), Harrison & Holyoak (1970), Holmes & Philipps (1996), McKean (1982), Rozendaal & Dekker (1989), Sujatnika *et al.* (1995), Watling (1983), White & Bruce (1986).

162. Yellow-throated Hanging-parrot

Loriculus pusillus

French: Coryllis à gorge jaune

German: Elfenpapageichen

Spanish: Loriculo de Java

Taxonomy. *Loriculus pusillus* G. R. Gray, 1859, no locality.

Forms a superspecies with *L. exilis* and *L. flosculus*. Monotypic.

Distribution. Java and Bali.

Descriptive notes. 12 cm. Green, more yellowish below; orange bill; large orange-yellow patch on throat; can have very faint orange band on nape; rump and uppertail-coverts red; legs pale orange. Female has smaller throat patch. Immature undescribed.

Habitat. Lowland swamp forest, montane forest, more open areas with *Casuarina* trees, up to 1850 m.

Food and Feeding. Observed feeding in flowering *Erythrina* trees, in *Ficus*, and at *Cassia siamea* flowers.

Breeding. Apr-May. Nest in hollow in tree, often a palm trunk or an old barbet hole; once

in top of tree-fern at the edge of primary forest. Eggs 2.

Movements. No certain information but considered probably nomadic.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. Considered generally uncommon throughout range in both Java and Bali.

Bibliography. Andrew (1985, 1992), van Balen *et al.* (1988), Collar *et al.* (1994), Hellebrekers & Hoogerwerf (1967), Hoogerwerf (1949), Inskipp *et al.* (1996), MacKinnon (1988), MacKinnon & Philipps (1993), Mason (1989), Nijman & Sözer (1996), Parrott & Andrew (1996), Rensch (1930).

163. Flores Hanging-parrot

Loriculus flosculus

French: Coryllis de Wallace

German: Florespapageichen

Spanish: Loriculo de Flores

Other common names: Wallace's Hanging-parrot

Taxonomy. *Loriculus flosculus* Wallace, 1864, Flores.

Forms a superspecies with *L. exilis* and *L. pusillus*, and sometimes considered conspecific with former. Monotypic.

Distribution. Flores (Lesser Sunda).

Descriptive notes. 11-12 cm. Green, lighter on underparts; bill red; throat with elongated red spot; nape tinged orange; rump and uppertail-coverts red; legs orange. Female has red on throat reduced or sometimes absent. Immature undescribed.

Habitat. Primary semi-evergreen forest, chiefly 800-1000 m but with records down to 450 m.

Food and Feeding. Most sightings in 1993 were in fruiting fig trees, and dependence or specialisation on this food resource judged likely.

Breeding. No information.

Movements. No information.

Status and Conservation. **VULNERABLE.**

CITES II. A BirdLife "restricted-range" species. Surveys in 1993 found it to be locally common in the Tanjung Kerita Mese proposed protected area, near Paku, but as little forest below 1000 m is included within existing protected areas on the island the species is considered vulnerable to rapid current habitat loss. In 1983 and 1984 total of 70 birds were reported as exported from Indonesia, and capture quotas were set for the species in most years down to 1993, although no trade was recorded. Commercial importation into the EC has been banned since Dec 1989.

Bibliography. Andrew (1992), Anon. (1993), Butchart *et al.* (1993, 1996), Coates & Bishop (1997), Collar *et al.* (1994), Jepson & Monk (1995), Robson (1988), Schmutz (1977, 1978), Sujatnika & Jepson (1995), Sujatnika *et al.* (1995), White & Bruce (1986).

Genus *AGAPORNIS* Selby, 1836

164. Grey-headed Lovebird

Agapornis canus

French: Inséparable à tête grise **German:** Grauköpfchen **Spanish:** Inseparable Malgache
Other common names: Madagascar Lovebird

Taxonomy. *Psittacus canus* J. F. Gmelin, 1788, Madagascar and Mauritius.
Two subspecies recognized.
Subspecies and Distribution.
A. c. canus (J. F. Gmelin, 1788) - W & E Madagascar.
A. c. ablectanea Bangs, 1918 - S Madagascar.
Introduced or thought to be introduced (presumed *canus*) to Comoros, Seychelles, Mauritius (failed), Rodrigues and Zanzibar (failed).

Descriptive notes. 15 cm; 25-31 g. Male has pale grey from head to upper breast; green upperparts, brighter on rump; yellow green underparts; black underwing-coverts. Bill whitish grey. Female more uniform green, with green underwing-coverts. Immature like female but with yellowish bill with black at base. Race *ablectanea* darker green above, less yellow below.
Habitat. Forest edges and clearings, wooded (e.g. *Medemia* palm) savanna, scrub and degraded forest, rice-fields and other cultivations bordering disturbed woodland and settlements, and less arid parts of semidesert zone: frequently seen on roads. Up to 1500 m, but generally in low-lying areas.

Food and Feeding. Fruits and seeds, mainly the latter, often eaten on ground; in one case (Comoros) unopened flowering shoots of the grass *Stenotaphrum micranthum*. Rice commonly sought, even in villages where set out to dry.
Breeding. Nov-Dec in Madagascar; Feb in Comoros. Nest in tree-hole, lined with finely chewed pieces of leaf, bark and grass. Eggs 3-6; in captivity, incubation c. 23 days, fledging period 43 days.
Movements. Sedentary.
Status and Conservation. Not globally threatened. CITES II. Generally widespread and common, more so in coastal areas, but now judged uncommon in E (where formerly common) and rare on the High Plateau. Listed for 25 protected areas in Madagascar. Can cause damage in rice-fields. Local trade is common.
Bibliography. Adamson *et al.* (1982), Appert (1968b, 1972), Baker (1990), Bangs (1918), Barnicoat (1980), Benson (1960), Benson *et al.* (1976-1977), Britton (1980a), Cheke (1987), Cheke & Diamond (1986), Dee (1986), Delacour (1930, 1932a, 1932b), Dowsett & Forbes-Watson (1993), Goodman & Putnam (1996), Griveaud (1960), Kaudern (1922), Langrand (1990), Lavauden (1937), Lever (1987), Louette (1988), McLaughlin (1996a, 1996b), Milon *et al.* (1973), Nicoll & Langrand (1989), Pakenham (1979), Penny (1974), Pidgeon & O'Connor (1985), Pringle (1985), Rand (1936), Seitre (1997), Sibree (1915), Snow (1978), van Someren (1947), Steinbacher (1972), Turner (1991).

165. Red-headed Lovebird

Agapornis pullarius

French: Inséparable à tête rouge **German:** Orangeköpfchen **Spanish:** Inseparable Carirrojo
Other common names: Red-faced Lovebird

Taxonomy. *Psittacus pullarius* Linnaeus, 1758, Asia, Ethiopia; error = Ghana.
Two subspecies recognized.
Subspecies and Distribution.
A. p. pullarius (Linnaeus, 1758) - patchily in Guinea, Sierra Leone and N Ivory Coast, and from Ghana E to Sudan and S into W Zaire and NW Angola, mainly N of Congo basin (southern boundaries unclear); also São Tomé.
A. p. ugandae Neumann, 1908 - E Zaire to W Ethiopia, W Kenya and NW Tanzania.

Descriptive notes. 13-15 cm; 29-50 g. Bright green with orange-red forehead and throat; rump bright blue; all but central tail feathers red at base, black in centre and green at tip; underwing-coverts black. Female has less bright forehead and throat, green underwing-coverts. Immature has face yellow. Race *ugandae* has paler blue rump.
Habitat. Mixed savanna woodland, light orchard bush, isolated patches of heavier woodland and subtropical humid primary and secondary forest and forest edge, riverine bushland, riparian forest, around inselbergs in savanna, and near areas of cultivation and pasture; mostly lowlands, but in E of range up to 2000 m.

Food and Feeding. Seeds of tall grasses, including *Sorghum*, taken from ground, also fruits of guavas and apparently figs.
Breeding. Nestlings and juveniles in Oct in Nigeria; Sept in Sierra Leone; Apr-Aug and Oct in Uganda and E Zaire. In Freetown area of Sierra Leone, appears to nest invariably in ant-nests in trees; said to nest where there are arboreal ant-nests in Sudan; one nest in Nigeria was in hole in occupied ant-nest attached to bole of tree 4 m up. Eggs 3-7; in captivity, incubation by female 22 days, nestling period 42 days.

Movements. Some populations sedentary, but others seem to behave as short-distance migrants, and all are perhaps capable of some nomadism. Considered to be a visitor of unclear seasonal status. Kagoro, Nigeria. Numbers appear to increase, Darfur, Nov-Feb, and certainly do so in rains. Cabinda. In E Africa birds subject to considerable local movements, occurring sporadically over much of Uganda and NW Tanzania.
Status and Conservation. Not globally threatened. CITES II. Generally rather uncommon, and never reported as abundant except locally in Ethiopia. In Sierra Leone, not uncommon in N woodlands, but less common further S with isolated population on Freetown Peninsula; significant numbers trapped each year as cage-birds; male's habit of sitting prominently just outside nest for long periods leads to most nests being robbed of young. Uncommon or rare in Liberia, Ghana and Benin. Uncommon in Gashaka-Gumti Game Reserve (now National Park), and rare in Kano State and Nindam Forest Reserve, Nigeria, although commonly on sale in most main towns (far commoner in last century). Rare in the Dzanga reserves, but common in Manovo-Gounda-St Floris and Bamingui-Bangoran National Parks, Central African Republic, with breeding proved in the latter park. Fairly common along whole Chad/Sudan border, Darfur, and indeed fairly common in Sudan. Much used as a cage-bird in Angola, where not common; and evidence of small amount of trade out of São Tomé. Race *ugandae* locally common. Most recent records in Kenya thought to represent wanderers, but a population apparently persists in Kakamega Forest. Generally frequent, locally abundant, in Ethiopia.

Bibliography. Atkinson *et al.* (1994), Bannerman (1953), Britton (1980a), Brown & Britton (1980), Cave & Macdonald (1955), Chapin (1939), Cheke & Walsh (1996), Claffey (1995), Dilger (1960, 1964, 1975), Dowsett & Forbes-Watson (1993), Dyer *et al.* (1986), Eccles (1988), Elgood *et al.* (1994), Evans & Balmford (1992), Fry *et al.* (1988), Green (1983, 1990), Green & Carroll (1991), Grimes (1987), Jones & Tye (1988), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Praed & Grant (1957, 1970), de Naurois (1994), Nielsen, A.V. (1964), Nikolaus (1987), Pinto (1983), Prestwick (1957), Savalli (1991), Serle (1957), Sharland & Wilkinson (1981), Short *et al.* (1990), Smith (1979a), Snow (1978), Thiollay (1985), Turner (1991), Zimmerman *et al.* (1996).

166. Black-winged Lovebird

Agapornis taranta

French: Inséparable d'Abyssinie **German:** Tarantapapagei **Spanish:** Inseparable Abisinio
Other common names: Abyssinian Lovebird

Taxonomy. *Psittacus taranta* Stanley, 1814, Pass of Taranta, Ethiopia.
Birds at higher altitudes are larger, but not subspecifically recognized. Monotypic.
Distribution. Ethiopia.

Descriptive notes. 16 cm; 49-66 g. Bright green with red bill, forehead and eye-ring; tail feathers marked yellow and barred black; flight-feathers and underwing-coverts black. Female without red on head, underwing-coverts green. Immature like female but with dusky yellow bill.
Habitat. Chiefly a highland bird, with optimal habitat, based on frequency, juniper-*Podocarpus* and olive-*Podocarpus*-juniper forest, 1800-3400 m, but also *Hagenia* forest above 2900 m and in broad-leaved tall-grass savanna and *Acacia* short-grass savanna in lower areas. Penetrates well-wooded gardens

in towns, including Addis Ababa.
Food and Feeding. Seeds; berries, e.g. junipers (*Juniperus*); and fruits, e.g. figs (*Ficus*).
Breeding. Possibly every month. Mar-Nov. Nest in tree trunk or branch, holes in walls and possibly weavers' nests, lined with vegetation and feathers. Eggs 5; in captivity, incubation period 25 days, and nestling period 49 days.
Movements. None recorded.
Status and Conservation. Not globally threatened. CITES II. Widespread and more frequently seen in 1989 than previously, perhaps owing to a reduction in roadside sales for the pet trade. Present in Abijata-Shala Lakes and Bale Mountains National Parks, but elsewhere considered a minor crop pest and exposed to risk from future increases in chemical spraying to control damage by other bird species.
Bibliography. Abdu Mohamud *et al.* (1992), Albrecht (1997), Ash & Gullick (1989), Benson (1945), Cheesman & Sclater (1935), Conacher (1976), Dilger (1960, 1964, 1975), Dowsett & Forbes-Watson (1993), Friedmann (1930a), Fry *et al.* (1988), Kirmse (1993), Mackworth-Praed & Grant (1957), Major & Cheesman (1935), Moreau (1948), Pain *et al.* (1975), Smith, G.A. (1979a), Smith, K.D. (1957), Snow (1978), Succow (1990), Urban (1980), Urban & Brown (1971).

167. Black-collared Lovebird

Agapornis swindernianus

French: Inséparable à collier noir **German:** Grünköpfchen **Spanish:** Inseparable Acolorado

Taxonomy. *Psittacus Swindernianus* Kuhl, 1820, Liberia.
Three subspecies recognized.
Subspecies and Distribution.
A. s. swindernianus (Kuhl, 1820) - patchily distributed in Liberia, Ivory Coast and Ghana.
A. s. zenkeri Reichenow, 1895 - Cameroon and Gabon E to S Central African Republic and W Zaire.
A. s. emini Neumann, 1908 - C & E Zaire E to W Uganda.
Descriptive notes. 13 cm, 39-41 g. Head green, with narrow black hind-collar and yellow neck; rump deep blue; rest of upperparts dark green with blackish flight-feathers; outer tail feathers with broad orange red markings against a black subterminal bar. Immature lacks collar. Race *zenkeri* replaces yellow with red on neck and below hind-collar, *emini* with less intense red than *zenkeri*.
Habitat. Mature and secondary lowland and gallery forest, 700-1200 m, particularly favouring fig trees and cultivated clearings. Found high in primary forest trees or low in secondary growth, depending on foliage level.
Food and Feeding. Fig seeds, especially from stranglers, and the fruit of *Rauwolfia*, *Harungana* and *Macaranga*, and ripe maize on the ground; repeatedly observed coming in small flocks (5-10)

at dawn to feed on fruit of oil palm, and noted at red flowers of *Spathodea* tree. Two stomachs contained seeds and berries; insects, including caterpillars and beetle larvae, also found.

Breeding. Nestlings Jan-Feb in Gabon. No other information, though nesting in E Zaïre and Uganda likely in Jul.

Movements. Flock sizes larger in dry season, Gabon, but no evidence of migration.

Status and Conservation. Not globally threatened. CITES II. Generally reported as rare or uncommon except in Gabon, where common; this perhaps reflects observer activity and

sensitization to the species. Rare, Liberia. Not uncommon, Yapo Forest, Ivory Coast, where also recorded from Azagny and Tai National Parks. Rare Ghana, where probably now confined to forest reserves, also Bia National Park. Rare in Dzanga reserves, Central African Republic. Rarely recorded in E Africa, but reasonably common, Bwamba lowlands, Uganda.

Bibliography. Bannerman (1953), Britton (1980a), Brosset & Erard (1986), Chapin (1939), Cunningham-van Someren (1948), Demey & Fishpool (1991, 1994), Dilger (1960, 1964, 1975), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Gatter (1988), Green & Carroll (1991), Grimes (1987), Lippens & Wille (1976), Macdonald (1980a), Macdonald & Taylor (1977), Mackworth-Praed & Grant (1957, 1970), Parkes (1960a), Short *et al.* (1990), Snow (1976, 1978), Turner (1991).

168. Rosy-faced Lovebird

Agapornis roseicollis

French: Inséparable roseorge **German:** Rosenköpfchen **Spanish:** Inseparable de Namibia
Other common names: Peach-faced Lovebird

Taxonomy. *Psittacus roseicollis* Vieillot, 1818. Goodhouse, north-west Cape Province. Two subspecies recognized.

Subspecies and Distribution.

A. r. catumbella Hall, 1952 - SW Angola N almost to Luanda.

A. r. roseicollis (Vieillot, 1818) - Namibia and South Africa.

Feral population (*roseicollis*) in Simonstown, Cape Peninsula.

Descriptive notes. 15-18 cm; 43-63 g. Pale grass green, somewhat darker above, with bright blue rump; peach pink face and upper chest, darker reddish crown. Bill yellowish; fleshy white eye-ring. Immature pale buff brown on face and upper chest. Race *catumbella* richer and brighter.

Habitat. Arid woodland, scrubby hillsides and tree-lined watercourses including river canyons, in rocky terrain, where rainfall exceeds 100 mm, and where water accessible. Coastal sandstone cliffs in Kisama National Park. Escapes occur in urban areas. Up to 1500 m.

Food and Feeding. Mainly seeds of *Albizia*

(also flowers) and *Acacia*, and buds and foliage of various plants including *Euphorbia*. Pest in grain fields, notably on maize; also eats cultivated sunflowers. Very dependent on water.

Breeding. Feb-Apr, i.e. late summer, when main seed pods ripening; but Jul in N of range. Nests in rock crevices although also utilizing nests of Sociable Weaver (*Philetarius socius*) and even buildings and bridges; nest cup-shaped, made of straw, twigs and other material. Eggs 4-6; incubation c. 23 days, by female only; fledging c. 43 days.

Movements. Resident, but wanders locally, e.g. when temporary waterholes dry up.

Status and Conservation. Not globally threatened. CITES II. Flocks of hundreds at good food sources, but otherwise in small flocks. Frequently kept as a cage-bird, Angola, and the export of thousands of birds has greatly contributed to the diminution of populations in the S of the country. Present in Kisama National Park near Luanda, and in Augrabies Falls and Kalahari Gemsbok National Parks, South Africa.

Bibliography. Brickell (1982), Brooke (1984a), Ciancy (1980), Dean *et al.* (1988), Dilger (1960, 1964, 1975), Dowsett & Forbes-Watson (1993), Dyck (1971), Fischdick *et al.* (1984), Fry *et al.* (1988), Ginn *et al.* (1989), Haugaard (1995), Hoesch (1940), Lever (1985), Lever (1987), Macdonald (1957), Mackworth-Praed & Grant (1962), Maclean (1993), Mebes (1977, 1978, 1981a, 1981b, 1982), Newman (1996), Pinto (1983), Preiss & Franck (1974), Rowan (1983), Smith (1979a), Snow (1978), Traylor (1963), Winterbottom (1969).

169. Fischer's Lovebird

Agapornis fischeri

French: Inséparable de Fischer **German:** Pfirsichköpfchen **Spanish:** Inseparable de Fischer

Taxonomy. *Agapornis fischeri* Reichenow, 1887, Ussure, Tanzania.

Sometimes treated as conspecific with *A. personatus*; also on occasion with *A. lilianae* and *A. nigrigenis*; perhaps best considered to form superspecies with all three. Monotypic.

Distribution. Virtually endemic to Tanzania S and E of L Victoria, but including some islands off southern shore; range centred on Serengeti. Feral populations exist in Mombasa, now apparently hybridizing with *A. personatus*. Recent records from Burundi and Rwanda appear to refer to wild birds interrupting in response to drought within normal range.

Descriptive notes. 15 cm; 42-58 g. Forehead and bill red, less intense on rest of head and shading on nape, sides of neck and throat to yellowish pink, then green on lower breast and belly; back, wings and tail dark green; uppertail-coverts dark blue. Immature has duller head.

Habitat. Wooded grasslands with *Acacia*, *Commiphora* and *Adansonia*, at 1100-2200 m, and cultivated areas to the W of its range; found to be commonest in savanna dominated by *Acacia tortilis*, with other *Acacia* and *Balanites aegyptiaca* the principal associates, and a ground layer of grasses made up of *Penisetum*, *Digitaria*, *Themeda* and *Eustachys*. In Serengeti present in all types of woodland and borassus palms (*Borassus aethiopum*); this latter is chief habitat in S of range. Riverine forest, dominated by *Ficus*, *Ziziphus*, *Tamarindus*, *Aphania*, *Garcinia* and *Eckbergia*, is an important dry season habitat. Avoids miombo woodland.

Food and Feeding. Essentially granivorous, including seeds of the grass *Penisetum mezianum* and weed *Achyranthes asper* collected from seedheads or off the ground; also takes *Acacia* seeds di-

rectly from the tree or on the ground. Fruit includes *Rhus villosa*, *Commiphora* and *Ficus capensis*. Drinks daily at waterholes and other surface water.

Breeding. Jan-Apr, Jun-Jul. Most nests 2-15 m up in dead trees or dead branches of living trees, commonly in old woodpecker or barbet holes in *Acacia tortilis* but also in natural cracks in *Commiphora trochae* branches, holes in *Adansonia* and frond-bases of *Borassus* palms; probably also sometimes in cliffs. In captivity: 3-8 eggs; incubation c. 23 days; nestling period 38 days.

Movements. Sedentary, although with local dry season movements, and irruptions in Jul-Aug some years into Rwanda and Burundi.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. Locally common, fairly common and widespread. Range centred on Serengeti National Park where generally common, but recorded also in Tarangire and Arusha National Parks. Total area of distribution c. 136,000 km², though possibly only 51,000 km² of suitable habitat within this. Large flocks of 1930's now greatly reduced (largest in recent survey 150); current total population estimated 290,205-1,002,210 birds, of which 103,205-815,210 lie within protected areas, the remaining 187,000 living at very low density outside them. The low densities are attributable to trade, with peak of 87,566 birds exported in 1987, and an average annual export of 56,481 in the years 1982-1990, probably representing a minimum offtake of 644,500 in the years 1982-1992, making it then the most highly traded parrot in the world. In 1992 no export quota was issued, suspending trade.

Bibliography. Anon. (1995d), Beesley (1973), Britton (1980a), Brown & Britton (1980), Cunningham-van Someren (1969, 1975), Dilger (1960, 1964, 1975), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Fuggles-Couchman (1984), Gaugris *et al.* (1981), Gerhart (1977), Lever (1987), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1957), Moreau (1945), Moyer (1995), Schmidt (1982), Short *et al.* (1990), Smith (1979a), Snow (1978), Thompson (1989, 1990), Thompson & Karanja (1989), Turner (1977a, 1991), Vande Weghe (1981), Zimmerman (1967), Zimmerman *et al.* (1996).

170. Yellow-collared Lovebird

Agapornis personatus

French: Inséparable masqué **German:** Schwarzköpfchen **Spanish:** Inseparable Cubecinegro
Other common names: Masked/Black-masked Lovebird

Taxonomy. *Agapornis personata* Reichenow, 1887, Serian, Tanzania.

Sometimes regarded as conspecific with *A. fischeri*, with which it does not, however, interbreed where naturally sympatric, although where introduced at L Naivasha and a few other highland sites in Kenya these two taxa have formed stable hybrids; also on occasion lumped with *A. lilianae* and *A. nigrigenis*; perhaps best considered to form superspecies with all three. Monotypic.

Distribution. Tanzania. No evidence of natural occurrence in Kenya, although ecological barrier unclear and feral populations exist in Mombasa (now apparently hybridizing with *A. fischeri*), as well as in Tanga and Dar es Salaam. Overlaps with *A. fischeri* from S of Lake Manyara to Babati.

Descriptive notes. 13-15 cm; 43-47 g. Head blackish brown with red bill and white eye-ring; breast yellow extending as collar onto nape; belly, wings and tail green, all but central tail feathers can be subterminally marked in orange and black but individually variable. Immature duller on head.

Habitat. Well-wooded bushland, *Acacia* thorn scrub, especially with scattered baobabs *Adansonia*, to which particularly partial, at 1100-1800 m. Avoids miombo woodland.

Food and Feeding. Diet very poorly known. Seeds of grasses and millet recorded, and feral birds eat *Cassia* seeds and those of weeds

on lawns.

Breeding. Mar, Apr, Jun, Jul and Aug, i.e. mainly in dry months. Nest a bulky structure of long stalks and strips of bark, in cavities of trees, especially *Adansonia*; feral populations use eaves and apertures used by other urban birds. In captivity: 3-8 eggs; incubation, by female only, c. 23 days; nestling period c. 44 days.

Movements. Sedentary.

Status and Conservation. Not globally threatened. CITES II. Locally common, and generally fairly so. Recorded from Tarangire (common) and Ruaha National Parks. The hybrid population at Lake Naivasha comprised some 6000 individuals in 1986.

Bibliography. Britton (1980a), Brown & Britton (1980), Cunningham-van Someren (1969), Dilger (1960, 1964, 1975), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Gerhart (1977), Lever (1987), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1957), Moreau (1945), Short *et al.* (1990), Smith (1979a), Snow (1978), Thompson (1989, 1990), Thompson & Karanja (1989), Turner (1977a, 1991), Wüst (1997), Zimmerman *et al.* (1996).

171. Nyasa Lovebird

Agapornis lilianae

French: Inséparable de Lilian **German:** Erdbeerköpfchen **Spanish:** Inseparable del Nyasa
Other common names: Lilian's Lovebird

Taxonomy. *Agapornis lilianae* Shelley, 1894, Liwonde, Upper Shire, Malawi.

Sometimes regarded as conspecific with *A. nigrigenis*; also on occasion with *A. fischeri* and *A. personatus*; perhaps best considered to form superspecies with all three. Monotypic.

Distribution. Isolated populations in S Tanzania, NW Mozambique and S end of L Malombe, Malawi; SE Zambia along middle Zambesi to N Zimbabwe, where patchy. Introduced into E Zambia with escapes in S Namibia.

Descriptive notes. 14 cm; 28-37 g. Similar to *A. fischeri* without blue uppertail-coverts, and with reddish pink extending from forehead, around eye to chin and throat, orange-green on rest of crown. Immature has blackish ear-coverts.

Habitat. Strong association with mopane (*Colophospermum mopane*) woodland in S of range, but also occurs in belts of *Acacia* on alluvium, riparian forest and at fig trees in N; presence in S Tanzania probably linked to areas of *Acacia* woodland. Avoids miombo (*Brachystegia*) woodland in Zambia.

Food and Feeding. Grass seeds including *Hyparrhenia*, millet and wild rice (*Oryza perennis*) and various others in low vleis areas; flowers and/or seeds or fruit of *Acacia albida*, *Erythrophleum africanum*, *Vitex duarumiana* and wild mango (*Cordia africana*).

Breeding. Jan-Mar and Jun-Jul in Zambia; possibly lays Jan and Feb in Malawi; 4 young, 2 well-grown and 2 much younger, in Apr, Zimbabwe. Nest a roofed structure in crevices in mopane trees and perhaps old nests of White-billed Buffalo-weavers (*Bubalornis albigularis*). In captivity: 3-8 eggs; incubation c. 22 days; nestling period 44 days.

Movements. Apparently sedentary.

Status and Conservation. Not globally threatened. CITES II. Common in most of range. Common in large flocks at only site, Malawi; often in large flocks, Zambia. Very common locally, and overall population not large and susceptible to overtrapping, Zimbabwe. Locally common, Mozambique.

Bibliography. Baker (1991), Benson (1953), Benson & Benson (1977), Benson *et al.* (1971), Clancey (1980, 1996), Davies (1991), Dilger (1960, 1964, 1975), Dowsett & Dowsett-Lemaire (1980, 1993), Dowsett & Forbes-Watson (1993), Fothergill (1984), Fry *et al.* (1988), Ginn *et al.* (1989), Howells (1985), Irwin (1981), Mackworth-Praed & Grant (1957, 1962), Maclean (1993), Moreau (1945), Rowan (1983), Smith, G.A. (1979a), Smith, K.D. (1950), Snow (1978), Turner (1991).

172. Black-cheeked Lovebird

Agapornis nigrigenis

French: Inséparable à joues noires **German:** Rußköpfchen **Spanish:** Inseparable Cachetón

Taxonomy. *Agapornis nigrigenis* W. L. Sclater, 1906, Muguzzi River, Zambia. Sometimes treated as a subspecies of *A. lilianae*, from which separated by a 100 km block of unsuitable miombo (*Brachystegia*) woodland; also on occasion lumped in single species with

A. fischeri and *A. personatus*; perhaps best considered to form superspecies with all three. Monotypic.

Distribution. S Zambia and formerly extreme N Zimbabwe at Victoria Falls, with old uncertain records from Namibia (Caprivi Strip).

Descriptive notes. 14 cm; (in captivity) male 38 g, female 43 g. Forehead and crown dark reddish brown, hindcrown and nape yellowish green, cheeks and throat blackish brown with white eye-ring and red bill; upper breast orange pink; rest green, tail with some inconspicuous pale orange and blackish barring (sometimes concealed). Immature has black marks on base of upper mandible.

Habitat. Medium-altitude deciduous woodland, dominated by mopane (*Colophospermum mopane*) but only where adjacent to woodland dominated by *Baikiaea plurijuga*, birds using mopane in the dry season and *Baikiaea* in the

rains. Usually within reasonable distance of reliable water source, at which birds drink daily.

Food and Feeding. Seeds of *Amaranthus*, *Rottboellia exaltata*, *Rhus quartiniana*, *Albizia anthelmintica*, *Combretum massambicense* and *Syzgium guineense*, and grass seeds *Hyparrhenia* and *Eragrostis*; also young leaves of *Pterocarpus antunesiana*.

Breeding. Nov-Dec in Zambia. Nest in large mopane trees. In captivity a dome-shaped nest is built in cavities. In captivity: 3-8 eggs; incubation c. 24 days; nestling period c. 41 days.

Movements. Subject to some local movements, possibly seasonal in nature, and said to be annual in the Senanga district of Zambia.

Status and Conservation. **ENDANGERED.** CITES II. A BirdLife "restricted-range" species. Decline (or inability to recover) attributed informally to replacement in 1950's of sorghum and millet by maize (birds used to be crop pests), although also to massive exploitation in 1920's, with a report of 16,000 being captured in four weeks in 1929 for the cagebird market. Current estimated total around 10,000 in two subpopulations, 6200 in S and 3800 in N. Present in Kafue National Park.

Bibliography. Benson & Irwin (1967), Benson *et al.* (1971), Clancey (1980, 1985), Collar & Andrew (1988), Collar & Stuart (1985), Collar *et al.* (1994), Dilger (1960, 1964, 1975), Dodman (1995a, 1995b, 1996), Dodman & Katanekwa (1995), Dowsett (1971a, 1972), Dowsett & Dowsett-Lemaire (1980, 1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Ginn *et al.* (1989), Irwin (1981), Killmer (1994), Lietzow (1984, 1997), Mackworth-Praed & Grant (1962), Maclean (1993), Moreau (1948), Perrin (1996), Smith, G.A. (1979a), Smith, R. (1994), Snow (1978), Them (1989).

173. Vasa Parrot

Coracopsis vasa

French: Perroquet vasa **German:** Großer Vasa **Spanish:** Loro Vasa
Other common names: Greater Vasa Parrot

Taxonomy. *Psittacus Vasa* Shaw, 1812, South Africa; error = east Madagascar. Three subspecies recognized.

Subspecies and Distribution.

C. v. comorensis (W. K. H. Peters, 1854) - Ngazidja (Grand Comoro), Mwali (Moheli) and Ndzuani (Anjouan) in Comoros.

C. v. drouhardi Lavauden, 1929 - W & S Madagascar.

C. v. vasa (Shaw, 1812) - E Madagascar

Introduced (presumably race *vasa*) to Reunion, but apparently died out.

Descriptive notes. 50 cm. Dark brown, slightly lighter on underparts with pale grey undertail-coverts, greyish wing-coverts and edges to primaries; rosy grey bare area on face. Bill light brown when breeding, dark grey otherwise. Some breeding birds lose most head feathers to reveal yellow or orange skin. Immature generally more brownish, bare area on face smaller. Race *drouhardi* slightly paler and smaller; *comorensis* paler, with brown undertail-coverts.

Habitat. Less tied to forest than *C. nigra*, present in humid and deciduous forests, coastal plains with coconut plantations, savannas including *Medemia* palm savanna with scrub and

relict forest, rice-fields and other cultivations adjacent to woodland, and subdesert areas, noted alighting on ground on sandbanks. Generally only to 1000 m.

Food and Feeding. Fruits (in one case *Cussonia*), berries, seeds. More granivorous than *C. nigra*, capable of eating maize on the stalk.

Breeding. Oct-Jan. In W Madagascar uses baobabs and several nests can be simultaneously active in same tree. Eggs 3; in captivity, incubation 17 days, nestling period 45-49 days.

Movements. Probably sedentary, but moving locally in search of food. Birds often fly very high over forest, sometimes by moonlight.

Status and Conservation. Not globally threatened. CITES II. Commoner than *C. nigra* in W Madagascar. Listed for 28 protected areas in Madagascar, and still fairly common in many areas. Causes some crop damage, and often persecuted in S. Hunted for food, taken for trade, and officially listed in 1970's as a pest species; there is now concern that levels of exploitation are excessive, owing to the zeal with which the birds are trapped by the Betsimisaraka people, who resent their raids on ricefields. Relatively common on Comoros.

Bibliography. Adamson *et al.* (1982), Appert (1972), Atkins (1991), Benson (1960, 1981), Benson *et al.* (1976-1977), Bowen (1989), Cheke & Diamond (1986), Dee (1986), Delacour (1930, 1932a, 1932b), Dowsett & Forbes-Watson (1993), Forbes-Watson (1969), Forbes-Watson & Turner (1973), Kaudern (1922), Langrand (1990), Lavauden (1929b, 1937), Louette (1988), Louette *et al.* (1988), McBride (1996), Milon *et al.* (1973), Nicoll & Langrand (1989), Parsons (1991), Pidgeon & O'Connor (1985), Pringle (1985), Rand (1936), Robiller & Meier (1989), Smith (1985b), Steinbacher (1972), Werner (1985), Wilkinson (1990, 1994), Wilkinson & Birkhead (1995), Wilkinson *et al.* (1992).

174. Black Parrot

Coracopsis nigra

French: Perroquet noir **German:** Rabenpapagei **Spanish:** Loro Negro
Other common names: Lesser Vasa Parrot

Taxonomy. *Psittacus niger* Linnaeus, 1758, eastern Madagascar.

Proposed race *barklyi* of Seychelles apparently indistinguishable from *sibilans*. Three subspecies recognized.

Subspecies and Distribution.

C. n. sibilans Milne-Edwards & Oustalet, 1885 - Ngazidja (Grand Comoro) and Ndzuani (Anjouan) in Comoros; population on Praslin, Seychelles, may have been introduced, but appears to have colonized Curieuse through natural dispersion.

C. n. libs Bangs, 1927 - W & S Madagascar.

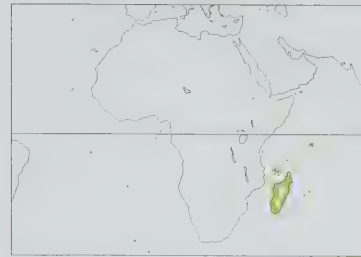

C. n. nigra (Linnaeus, 1758) - E Madagascar.

Introduced (presumably race *nigra*) to Mauritius.

Descriptive notes. 35-40 cm; 315 g (nominate *nigra*), 132-153 g (*sibilans* on Seychelles). Dark brown, with greyish brown undertail-coverts and grey cast to primaries, bill dusky. When breeding, plumage has iridescent green sheen and bill pale, and birds show a fleshy protrusion from the cloaca. Naked skin around eye rosy grey. Immature duller and browner, bare facial patch smaller. Race *libs* slightly smaller and paler; *sibilans* considerably smaller, no grey in primaries.

Habitat. Dense humid and waterlogged forest including mangroves, but also savanna, dry forest, secondary woodland, up to 2050 m. On Mt Karthala, Ngazidja, more altitudinally restricted than *C. vasa*.

Food and Feeding. Fruits, berries, flowers and seeds. More frugivorous than *C. vasa*, descending into shrubbery when foraging, and with taste for *Azela bijuga*; also recorded taking seeds of *Cinnamosma fragrans*, blossoms of *Symphonia* and fruits of *Chassalia*. On Comoros reported to

attack young cacao pods, and seen feeding on leaves, nipping edges of some, plucking others to hold in feet. On Praslin, Seychelles, main foods are *Verschaffeltia splendida*, *Averrhoa bilimbi*, *Phoenixophorium borsigionum*, *Deckenia nobilis*, *Chrysobalanus icaco* and *Ficus rubra*, with seasonal partiality for mangoes (*Mangifera indica*); buds of *Dillenia* and shoots of *Casuarina* are also targeted.

Breeding. Nov-Jan. Nests in hollow limbs or tree holes. Eggs 2-3; incubation period 18 days (14-16 recorded in captivity); fledging 5-7 weeks (37-48 days in captivity). In captivity only the female fed the young.

Movements. Sedentary, but with daily dispersals in search of food.

Status and Conservation. Not globally threatened. CITES II. Common on Madagascar, though less so than *C. vasa* in W; in 19th century considered commoner overall than *C. vasa*. Listed for 37 protected areas in Madagascar. Hunted for food, taken for trade, and officially listed in 1970's as a pest species. On Comoros relatively common on Ngazidja, rare Ndzuani. Population on Seychelles best known and perhaps best protected, since virtually confined to the Vallée de Mai Reserve, Praslin, established to conserve the remarkable coco-de-mer palm (*Laodicea maldivicum*); at least 58 were present, 1983-1984, and probably the population lies between 70 and 100. Nest-site competition from Common Mynas (*Acridotheres tristis*) may be a problem.

Bibliography. Albignac (1970), Appert (1972), Benson (1960, 1981), Benson *et al.* (1976-1977), Bullock (1990), Dee (1986), Delacour (1930, 1932a), Diamond, A.W. Genus *PSITTACUS* Linnaeus, 1758

175. Grey Parrot

Psittacus erithacus

French: Perroquet jaco **German:** Graupapagei **Spanish:** Loro Yaco
Other common names: African Grey Parrot

Taxonomy. *Psittacus erithacus* Linnaeus, 1758, Ghana.

Race *timneh* may be separate species, with very little interbreeding and fairly distinctive voice. Proposed race *princeps*, from Principe in the Gulf of Guinea, is not distinguishable from nominate. Two subspecies recognized.

Subspecies and Distribution.

P. e. timneh Fraser, 1844 - Sierra Leone to Ivory Coast (at least 70 km E of R Bandama), with isolated populations in Guinea-Bissau and S Mali.

P. e. erithacus Linnaeus, 1758 - Ivory Coast E to W Kenya and NW Tanzania and S to SC Zaire and Cabinda, including Principe and (probably introduced) São Tomé.

Feral population of *timneh* alongside nominate race at Abidjan, Ivory Coast. Feral populations of nominate race in many African cities.

Descriptive notes. 28-39 cm; 402-490 g. Bare facial area around eye whitish, head scaled white on grey extending onto darker grey back and breast; wings mid-grey, primaries blackish grey; tail and tail-coverts bright red; bill and legs grey to blackish. Size, notably that of the bill, individually variable independent of age, as is the intensity of the grey and the amount of red, which sometimes extends onto the belly. Immature has dark red tail tips. Race *timneh* darker grey with dull grey-red tail; smaller.

Habitat. Generally lowland moist forest, both primary and secondary, including edges and

clearings, and also at times occupying mangroves, gallery forest, savanna woodland, cultivations; in E of range up to 2200 m. Strongly associated with oil-palms (*Elaeis guineensis*) for food and raphia palms overhanging large watercourses for roosts, but also roosts on offshore islands. Although prefers secondary forest in Gabon, on Principe densities highest in lowland primary forest, intermediate in montane primary forest, and lowest in coconut plantations.

Food and Feeding. Fruits and seeds, notably the oily flesh but not stone of oil-palm, the most preferred food in Gabon, also *Ficus*, *Heisteria*, *Dacryodes*, *Petersianthus*, *Combretum*, *Macaranga*, *Raphia*, *Harungana*, *Ceiba*, *Blighia*, *Bombax*, *Celtis*, *Caccia*, *Petersianthus*, *Parkia*, *Terminalia*; apparently attracted to red fruits, e.g. *Cola tragacantha*. Recorded also taking *Prunus africanum*, *Pseudospondias microcarpa* and maize, to which much damage can be done, Angola, although no evidence of such crop destruction, Ghana. Birds are judged to travel considerable distances in search of fruiting trees.

Breeding. Nov-Apr in W Africa, Principe and Gabon; Jun-Jul in E Africa; Jul-Dec in Zaire. Nest in hole generally high in tall tree, e.g. *Terminalia superba*, *Ceiba pentandra*, *Distemonanthus benthamianus*. Most nests solitary, but on Principe, one or two nests per tree, in Ghana rarely up to three in one tree. Eggs 2-3, rarely 4; incubation period 21-30 days or longer, probably depending on sequence of egg in clutch; young leave the nest after c. 80 days.

On following pages: 176. Brown-necked Parrot (*Poicephalus robustus*); 177. Red-fronted Parrot (*Poicephalus gulielmi*); 178. Brown Parrot (*Poicephalus meyeri*); 179. Rüppell's Parrot (*Poicephalus rueppellii*); 180. Brown-headed Parrot (*Poicephalus cryptoxanthus*); 181. Niam-niam Parrot (*Poicephalus crassus*); 182. Red-bellied Parrot (*Poicephalus rufiventris*); 183. Senegal Parrot (*Poicephalus senegalus*); 184. Yellow-fronted Parrot (*Poicephalus flavifrons*).

Movements. Resident, although in Yapo Forest, Ivory Coast, most sightings were Nov-Feb. In Kibale Forest Reserve, W Uganda, abundance related to presence or absence of fruiting trees, with largest numbers appearing when particular tree species producing a seed crop, while at other times months might pass without a sighting, which suggests birds in the region range over a very large area. Short-distance movements occur between roosting and feeding areas, e.g. from inshore island roosts, Guinea Bissau. In Ghana evidence suggests that evergreen forest is used in dry season for breeding, with semi-deciduous forest belt then being largely deserted, birds returning there only after breeding.

Status and Conservation. Not globally threatened. CITES II. Locally abundant with a very large range, hence with a high world population. However, clearly must suffer to some degree from forest destruction, especially loss of large nesting trees. More importantly, second most heavily traded parrot in world in period 1982–1989 after *Agapornis fischeri*, with an average annual export from Africa of 47,357 birds. This trade is judged to be the cause of its decline from common in the recent past to relative current rarity in Liberia, where other than in Sapo National Park only a few birds were observed, 1988–1990. Similarly in Ghana chronic exploitation since at least the 1870's, and in spite of a 1986 ban, has reduced local populations that numbered many hundreds in 1940's to twos and threes today, e.g. in Bia National Park, although the total population in the country is still estimated to be 30,000–80,000 birds. Generally uncommon in Sierra Leone, with large decline since 1930's and 1940's; now confined to mangrove belt and forests of E. Common throughout forest zone S of 8° N in Ivory Coast, where population of nominate race (E part of country) is probably 10,000–25,000; likewise in many areas in rest of range, including Nigeria, Congo and Cabinda: thus, over 500 in oil-palm plantation just outside Korup National Park, Cameroon, and abundant in the park with little sign of trade. Several roosts in Gabon accommodate 5000–6000 birds nightly, and one in the N takes 10,000. Declining but still common on Principe, despite capture of some 1500 chicks per year. An abundant resident (10–100 seen or heard daily) of the two Dzanga reserves, Central African Republic. Around Kinshasa, Zaire, large flocks (200) are now gone, possibly owing to trade, and the species is also diminishing around Congo cities. In Uganda occurs in Budongo, Bugoma and Bwamba forest reserves plus Rwenzori National Park. In Kenya now absent from several forests where previously reported, and virtually now only known from Kakamega Forest where although still locally common in 1980's only 10 reportedly survived in mid-1990's.

Genus *POICEPHALUS* Swainson, 1837

176. Brown-necked Parrot

Poicephalus robustus

French: Perroquet robuste **German:** Kappapagei **Spanish:** Lorito Robusto
Other common names: Cape Parrot

Taxonomy. *Psittacus robustus* J. F. Gmelin, 1788, east Cape Province.

Forms a parapatric species pair with *P. gulielmi*. Race *suaehelicus* sometimes considered a separate species, incorporating *fuscicollis*, but voices claimed to be identical and morphological differences rather slight; nevertheless, notable differences in habitat preference suggest that treatment as separate species may be justified, although birds of W Africa may show more similarities to nominate *robustus* than to *suaehelicus*: within race *fuscicollis*, populations of lower R Congo and Cabinda are closest to *suaehelicus*. Three subspecies currently recognized

Subspecies and Distribution.

P. r. fuscicollis (Kuhl, 1820) - patchily from Gambia to EC Nigeria, lower R Congo and Cabinda (N Angola).

P. r. suaehelicus Reichenow, 1898 - E & CS Angola through Rwanda (one record in Uganda) to C Tanzania (Ngurus), and S to extreme N Botswana and extreme NE South Africa.

P. r. robustus (J. F. Gmelin, 1788) - E South Africa.

Descriptive notes. 30–36 cm; 225–401 g. Head, throat and neck yellowish brown; body and wings dark green; thighs and outer edges of wings orange red; tail and flight-feathers black. Bill large. Some yellow feathers or other plumage abnormality in c. 20% of specimens. Female typically has red forehead. Juvenile has brownish olive head and neck, reddish ear-coverts, without red on tibia and wing edge. Race *suaehelicus* larger, with heavier and more pointed bill, and silvery grey head and neck; *fuscicollis* smaller than *suaehelicus*, and tinged more bluish.

Habitat. Nominate *robustus* occupies montane mist-belt evergreen *Podocarpus* forest in temperate zone. Race *suaehelicus* uses many types of woodland, chiefly well developed formations such as riparian fringing forest, intervening mopane and baobab woodland, undisturbed *Baikiaea*, and open or dense tall *Brachystegia*, with lowland or mid-altitude evergreen forest used for roosting but not feeding; in Tanzania ranges mostly only up to 300 m, 925 m in Ngurus; in Angola no higher than 1500 m, but almost reaching 2000 m in Malawi, and up to 4000 m on Kivu, Zaire. Race *fuscicollis* uses mature wooded savanna, in Ivory Coast mainly in *Borassus aethiopum* palm woodland in the forest-savanna mosaic; in Gambia it prefers *Rhizophora* mangroves, and these are probably the main habitat of this race.

Food and Feeding. Seeds, nuts, berries and nectar. In South Africa fruits of the yellow-woods *Podocarpus falcatus* and *P. latifolius*, *P. henkelli*, *Harpephyllum caffrum*, *Olea capensis*, *Mimusops caffra*, *Acacia molissima*, *Melia azedarach*, *Eucalyptus*, *Ficus*, *Terminalia*, *Calodendron capense*, and *Commiphora*, also seeds of introduced *Acacia meurnsii*. In Zimbabwe most favoured food source is nut of mobola plum (*Parinari curatellifolia*), widespread in wetter areas and with extended fruiting period, Jul–Nov, with *Monotes glaber* seeds in dry season, also *Erythrina* (seeds and nectar), *Uapaca*, *Pseudolachnostylis maprouneifolia*, *Syzygium cordatum*, *S. guineense*, *Lannea discolor*, *Celtis africana*, *Ricinodendron rautanenii* and *Diospyros mespiliformis*, with a heavy dependence on *Ziziphus abyssinica* berries, Aug–Oct. *Adansonia* fruits eaten, Angola. Drinks regularly at certain places in early morning.

Breeding. Recorded most months of year in S Africa, with chief period apparently Mar–Apr in Malawi, Apr–Jun in Zambia; recorded in Jul in Zaire; Feb–Apr in Gambia. Nest chiefly in a natural hole in trunk of dead *Podocarpus falcatus* in South Africa, but elsewhere recorded in baobabs and in mangroves in Gambia. Up to 4 eggs; incubation 26–28 days; nestling period 8–11 weeks.

Movements. Some populations or parts of populations resident, with others wandering extensively during dry seasons in search of food. Fruiting of *Syzygium* and *Uapaca* appears to cause a regular migration by part of Zambezi Valley population to the central plateau of Zimbabwe (Trelawney district), birds arriving in Aug, leaving by Dec. although in Matobo National Park the period of occupancy is May–Oct. Similarly, a regular post-breeding visitor to submontane forest, Malawi in Nov–Feb. Considered probably casual visitor rather than true African migrant in Nigeria, owing to extended range of months recorded. Subject to local movements in some years in the northern savannas of Ghana. Birds in the mountain forests of the SE Cape, South Africa, undertake three different types of excursion into lower areas: daily flights, short visits with overnight stops, and more extensive periodic wanderings. These are largely prompted by the availability of *Podocarpus* fruits.

Status and Conservation. Not globally threatened. CITES II. Generally scarce, but patchily common. 1500–5000 birds. South Africa, with trapping for trade apparently the cause of decline, although populations survive in over 10 conserved areas. Common, Middle Zambezi, and in the Ulugurus, Tanzania; locally common in Zambia, but sparse in N Botswana and uncommon and very local in Angola. Generally scarce or rare throughout W Africa except Ghana, where fairly common; scarce and local in Gambia; rare and local, probably only casual in Nigeria; only one record from Sierra Leone, in Nov 1938, and only a doubtful one from Togo. Annual movement out of Zambezi Valley to central plateau, Zimbabwe, reflects food shortages in former, so progressive destruction of indigenous woodland in latter area will render the species much more vulnerable.

177. Red-fronted Parrot

Poicephalus gulielmi

French: Perroquet à calotte rouge **German:** Kongopapagei **Spanish:** Lorito Frentirrojo
Other common names: Red-crowned/Red-headed/Jardine's Parrot

Taxonomy. *Pionus gulielmi* Jardine, 1849. River Congo.

Forms a parapatric species pair with *P. robustus*. Birds of Kenya highlands formerly separated as race *permistus*; nominate race includes doubtful race *aubryanus*. Three subspecies currently recognized.

Subspecies and Distribution.

P. g. fantiensis Neumann, 1908 - Liberia E to Ghana.

P. g. gulielmi (Jardine, 1849) - Cameroon S to Cabinda (N Angola) and E to E Zaire and SW Uganda.

P. g. massaicus (Fischer & Reichenow, 1884) - W & C Kenya and N Tanzania.

Descriptive notes. 26–30 cm; 255–300 g. Green on head, underparts and rump, with forehead, crown, thighs and leading edge of wing orange red, back and wings brownish black edged green, flight-feathers and tail brownish black; iris reddish orange in male, orange brown in female. Immature duller, without red. Race *massaicus* paler, with smaller bill; *fantiensis* replaces orange red with orange, and overall smaller.

Habitat. Primary lowland rain forest, secondary forest, shade trees in coffee plantations, and adjacent clearings. In montane areas in E of range found at 1600–2550 m and even 3250

m, where occupies *Podocarpus* and *Juniperus* forests.

Food and Feeding. Seeds (e.g. from *Spathodea* pods), various palm fruits including oil-palm (*Elaeis guineensis*), large grains, pods of *Podocarpus* and *Cedrus*, wild olives, flowers or seeds of *Grevillea robusta*, and even insects.

Breeding. Evidence in W Africa feeble: members of a pair at hole in dead tree in Jul, Ivory Coast, were possibly breeding; young on wing in May, Ghana; in or around Jan, Gabon; Sept in N Zaire, Oct in C Zaire, Apr–May in S Zaire; Jan and Nov, E Africa, reportedly also Jun and Sept–Nov, with evidence for Mar. Nest in natural hollow of living tree, in one study 13 in *Hagenia abyssinica*, 4 in *Podocarpus*, 1 in *Juniperus*. Eggs 2–4; incubation period 26–28 days.

Movements. Resident, but at one site in Central African Republic large flocks noted several times a year, and occasional absences also recorded during middle months of year, Kenya.

Status and Conservation. Not globally threatened. CITES II. Rare to fairly common, W Africa, with few records, Ivory Coast, although 35 seen adjacent to Maraoúé National Park. Present in Kakum and Bia National Parks, Ghana, with flocks of up to 30 sometimes in latter. Uncommon in Korup National Park, Cameroon, fairly rare, Gabon, but common in small range, Cabinda, Angola. Uncommon in Dzanga reserves and present in Manovo-Gounda-St Floris National Park, Central African Republic. Locally common and widespread in highlands, E Africa, often forming large roosting flocks, but local declines in Kenya attributable to deforestation possibly coupled with aversion to secondary woodland. Trapping continues throughout the year on Mt Kilimanjaro and may lead to local extinction there. International

trade figures recorded for the period 1987–1993 still unclear, but apparently as many as 16,000 birds involved, with some uncertainty over countries of origin.

Bibliography. Bannerman (1953), Brickell (1987), Britton (1980a), Brosset & Énard (1986), Brown & Britton (1980), Chapin (1939), Cordeiro (1994), Demey & Fishpool (1991), Dowsett & Forbes-Watson (1993), Fisk (1991), Friedmann (1930a), Fry *et al.* (1988), Green & Carroll (1991), Grimes (1987), Helsen (1996), Hüton (1994a, 1994b), Holyoak, D.M. & Holyoak (1972), Holyoak, D.T. & Seddon (1990b), Jackson & Schlater (1938), Krüwer (1990), Laubscher (1997c), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Praed & Grant (1957, 1962, 1970), Morgan-Davies & Peterson (1976), Pinto (1983), Rodewald *et al.* (1994), Sessions (1966), Short *et al.* (1990), Snow (1978), Stoodley (1978b), Taylor & Macdonald (1978b), Thiollay (1985), Traylor (1963), Walters (1976), Westen (1983), Zimmerman *et al.* (1996).

178. Brown Parrot
Poicephalus meyeri

French: Perroquet de Meyer **German:** Goldbugpapagei **Spanish:** Lorito de Meyer
Other common names: Meyer's Parrot

Taxonomy. *Psittacus Meyer* Cretzschmar, 1827, Kordofan. Forms a superspecies with *P. rueppellii*, *P. cryptoxanthus* and *P. crassus*, and possibly others. Much intergradation between races, and also variation within each, indicating need for revision. Six subspecies currently recognized.

Subspecies and Distribution.
P. m. meyeri (Cretzschmar, 1827) - NE Cameroon through S Chad, N Central African Republic and N Zaire to S Sudan and W Ethiopia.
P. m. saturatus (Sharpe, 1901) - W Kenya and Uganda to E Zaire, Rwanda, Burundi and NW Tanzania.
P. m. matschiei Neumann, 1898 - SE Zaire and W & C Tanzania to E Angola, N Zambia and N Malawi.
P. m. reichenowi Neumann, 1898 - W Angola.
P. m. damarensis Neumann, 1898 - S Angola, N & C Namibia and NW Botswana.
P. m. transvaalensis Neumann, 1899 - S Zambia and N Mozambique, through E Botswana and Zimbabwe to N South Africa.

Descriptive notes. 21–25 cm; 100–150 g. Head, back, wings and tail dull brown, belly and rump green or turquoise, underparts washed yellow; variable amount of yellow on flanks, shoulders and crown (often absent from last). Underwing-coverts yellow. Immature lacks yellow markings. Race *saturatus* darker, *matschiei* with bluer tinging to green, *transvaalensis* bluer still and smaller, *reichenowi* like *matschiei* but large with no yellow on crown, *damarensis* like *matschiei* but large.

Habitat. Wide range of open woodland and riparian habitats, with obligate proximity to water in Angola and where sympatric with *P.*

rufiventris uses riverine forest not open savanna, although in drier areas than *P. cryptoxanthus* in Mozambique. Mixed lowland short- and tall-grass savanna, including those types dominated by *Terminalia laxiflora* and *Isobertinia doka*, *Combretum* bushlands and *Acacia tortilis* grassland, plus *Syzygium-Adina* riparian woodland, gallery forest, *Brachystegia* woodland along watercourses, riverine *Acacia*. In Darfur, Sudan, abundance linked to *Acacia albidia*, and this species and *A. nigrescens* also favoured in South Africa. 600–2200 m in E Africa, 900–1350 m in Malawi.

Food and Feeding. Fruits of large riverine trees such as *Azelia quanzensis*, *Melia volkensii* and *Ficus sycamorus*: seen excavating the large fruits of *Kigelia africana*; also figs, marulas, and is fond of cultivated oranges. Seed pods of trees, particularly the green pods of several *Acacia* species; only bird noted to feed on seeds of *Brachystegia* and other leguminous trees in miombo woodland. Other food-plants include *Ziziphus abyssinica*, *Uapaca nitidula*, *Monotes glaber*, *Combretum*, *Grewia*, *Sclerocarya*, *Pseudolachnostylis* and *Schotia*. Reported raiding grain fields, and recorded as taking caterpillars and other insects.

Breeding. Apr–Oct in Ethiopia, and similarly extended, patchily Feb–Dec in E Africa; nests with young in Jan in Sudan; May–Sept in Angola; Apr–May in Botswana; Jun in Malawi; Jan–Aug, chiefly Apr–May, in Zimbabwe; Mar–Jun in South Africa. Commonly uses old woodpecker holes, usually in vertical trunks at 3–7 m, with use continuing in successive years. Eggs 2–4, probably staggered; incubation 29–31 days; fledging 60–84 days.

Movements. Resident, although local movement or nomadism occurs, Botswana and South Africa.

Status and Conservation. Not globally threatened. CITES II. Common, NE Central African Republic, where present (breeding) and common in Manovo-Gounda-St Floris and Bamingui-Bangoran National Parks. Very common, W Darfur; fairly common elsewhere, Sudan. Common breeding resident, C Kenya. Seen daily, Ajai's Game Reserve, Uganda. Present but uncommon in Serengeti National Park, Tanzania. In Zambia and Malawi fairly common locally, while in Zimbabwe it is the only widespread and common parrot, but snared by local tribesmen, Middle Zambezi, because of the damage it does to ripening *Ziziphus* berries, an important human food. Common, N Botswana, sparser in E. The commonest parrot in Angola, where considered a crop pest, and present in Kangandala National Park and Giant Sable Strict Nature Reserve. Generally scarce and localized, Transvaal, and much less widespread and numerous than in last century; formerly notorious there for damage to orange orchards, also eating grain and taking maize from cobs.

Bibliography. Bannerman (1953), Benson & Benson (1977), Benson *et al.* (1971), Bretagnolle (1993), Brickell (1985), Britton (1980a), Cave & Macdonald (1955), Chapin (1939), Clancey (1977, 1980, 1996), Dean *et al.* (1988), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Fuggles-Couchman (1984), Ginn (1971), Ginn *et al.* (1989), Green (1983), Greenway, K.W. (1967), Günther & Feiler (1986), Harwin (1961), Hawkins (1972), Holyoak & Holyoak (1972), Howells (1985), Irwin (1981), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Praed & Grant (1957, 1962, 1970), Maclean (1993), Massa (1995), Nikolaus (1987), Penry (1994), Pinto (1983), Rowan (1983), Schmidt (1982), Short *et al.* (1990), Snow (1978), Stubblefield (1994), Tarboton (1976), Tarboton *et al.* (1987), Wilson, N. & Wilson (1994), Wilson, R.T. (1982), Wirminghaus (1995), Wooldridge (1969), Zimmerman *et al.* (1996).

179. Rüppell's Parrot
Poicephalus rueppellii

French: Perroquet de Rüppell **German:** Rüppelpapagei **Spanish:** Lorito de Rüppell

Taxonomy. *Psittacus Rüppellii* G. R. Gray, 1849, Nunez River, French Guinea; error = Damaraland. Forms a superspecies with *P. meyeri*, *P. cryptoxanthus* and *P. crassus*, and possibly others. Monotypic.

Distribution. SW Angola and N & C Namibia.

Descriptive notes. 22–25 cm; 98–140 g. Dusky brown with slight blue wash on rump and tail-coverts. Carpal joint, leading edge of wing and underwing-coverts yellow, thighs yellow. Female similar but with rump and uppertail-coverts blue, lower belly to undertail-coverts dull blue. Immature like female but yellow absent or duller, wing feathers tipped or margined whitish.

Habitat. Well developed dry *Acacia* woodland along watercourses, also dry *Euphorbia* forests, *Brachystegia* woodland, *Adansonia*-dominated thornveld, and montane *Commiphora*/*Acacia* formations when extending upslope (generally

little above 1500 m).

Food and Feeding. Pods, e.g. of *Acacia* and *Faidherbia*; flowers, e.g. *Grewia*; fruits of *Ficus*, fruit endocarp of *Acacia* and *Commiphora*; seeds, e.g. of *Elephantorrhiza*, *Prosopis juliflora* and *Combretum imberbe*; nectar of flowering mistletoe (*Tapinanthus*), and young shoots in the canopy of taller trees and bushes; also insect larvae.

Breeding. Feb in Namibia; around Mar–Apr in Angola, but also reported later in year, with young in nest in Aug. One nest was in the dead branch of an *Acacia*, 3 m from ground, and occupied at least two years in succession; another was 5 m up in baobab, a third in an *Acacia*. Eggs 3–5; in captivity, fledging at c. 4 months.

Movements. Resident, but partly nomadic.

Status and Conservation. Not globally threatened. CITES II. Fairly common in suitable habitat, but only 9000 birds now estimated in Namibia, and its popularity among bird-fanciers coupled with its relatively restricted range means a significant reduction in overall numbers could easily occur; some illegal trading certainly occurs. Fairly common in S Angola, and frequent in Kissama National Park.

Bibliography. Brickell (1985), Clancey (1980), Dean (1974), Dean *et al.* (1988), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Ginn *et al.* (1989), Günther & Feiler (1986), Heinrich (1958), Holyoak & Holyoak (1972), Macdonald (1957), Mackworth-Praed & Grant (1962), Maclean (1993), Manning (1995), Meyer de Schauensee (1933), Moat (1996), Nelson (1994), Newman (1996), Pinto (1983), Rowan (1983), Selman & Hunter (1996), Snow (1978), Sweeney (1995f), Traylor (1963), Wooldridge (1969).

180. Brown-headed Parrot
Poicephalus cryptoxanthus

French: Perroquet à tête brune **German:** Braunkopfpapagei **Spanish:** Lorito Cabecipardo

Taxonomy. *Psittacus (Poicephalus)* [sic] *cryptoxanthus* W. K. H. Peters, 1854, Inhambane, Mozambique.

Forms superspecies with *P. meyeri*, *P. rueppellii* and *P. crassus*, and possibly others. Believed to hybridize with *P. meyeri* in SE Zimbabwe, although this is perhaps not as extensive as once thought: birds with yellow shoulders may be aberrant birds of present species. In past considered conspecific with *P. crassus*. Proposed race *zanzibarius*, of Zanzibar and Pemba, indistinct from *tanganyikae*, which itself is sometimes regarded as invalid. Two subspecies currently recognized.

Subspecies and Distribution.

P. c. tanganyikae Bowen, 1930 - SE Kenya, Zanzibar and Pemba to S Malawi and Mozambique N of R Save.

P. c. cryptoxanthus (W. K. H. Peters, 1854) - SE Zimbabwe and Mozambique S of R Save to NE South Africa.

Descriptive notes. 23–25 cm. 121–156 g. Head and neck dusky brown, back and wings brownish green, rump yellowish green, tail greenish brown, underparts green, underwing-coverts yellow. Juvenile generally duller, with yellowish olive on breast and neck. Supposed hybrids with *P. meyeri* show some yellow over head and loss of green in brownish back, with bluish in rump and uppertail-coverts. Race *tanganyikae* greener above, richer below.

Habitat. Semi-arid and subhumid bush, thornveld, open wooded savanna and woodland, including areas with large baobabs or figs, riparian forest, coconut and cashew-nut plantations, edges of smallholdings, and mangroves, up to 1200 m.

Food and Feeding. Seeds, e.g. *Erythrina* and *Adansonia*; nuts; fruits, particularly of figs (*Ficus*), *Pseudocadia zambesica* and berries, e.g. of cultivated cassava; pods of *Acacia* and *Albizia gummifera*; nectar, apparently, of *Aloe marlothii* and *Kigelia pinnata*; and coconut inflorescences and green shoots of trees. Known to raid millet and maize crops.

Breeding. Apr–Oct in S Africa; May in Malawi; Jul and Sept in Mozambique; Apr, Jun and Jul in E Africa, but probably Sept–Oct on Zanzibar and Pemba. Nest in unlined hole in tree. Eggs 2–3; incubation c. 28 days, by female only; fledging period c. 12 weeks.

Movements. Resident. In Transvaal probably moves locally in response to fruiting seasons of trees.

Status and Conservation. Not globally threatened. CITES II. Locally common, E Transvaal, especially in Kruger National Park. Common, especially in *Acacia* below 600 m, Malawi. The common small parrot of Mozambique. Common Pemba. Frequent, Wasiri I, S Kenya, and common, Shimoni, but local and uncommon elsewhere in Kenya. Persistently destructive of grain crops.

Bibliography. Benson (1953), Benson & Benson (1977), Brickell (1984c), Britton (1980a), Clancey (1977, 1980, 1996), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Ginn *et al.* (1989), Holyoak & Holyoak (1972), Irwin (1981), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1957, 1962), Maclean (1993), Pakenham (1979), Prestwick (1955), Rowan (1983), Ryall (1991, 1994), Short *et al.* (1990), Snow (1978), Tarboton *et al.* (1987), Taylor (1996), Vernon (1987), Wirminghaus (1995), Zimmerman *et al.* (1996).

181. Niam-niam Parrot
Poicephalus crassus

French: Perroquet des niam-niam **German:** Niamniampapagei **Spanish:** Lorito Niam-niam

Taxonomy. *Pionias crassus* Sharpe, 1884, Ndoruma, upper Uelle River.

Forms a superspecies with *P. meyeri*, *P. rueppellii* and *P. cryptoxanthus*, and possibly others. Formerly treated as a race of *P. cryptoxanthus*, to which is morphologically extremely close. Monotypic. **Distribution.** SW Chad through Central African Republic to extreme SW Sudan and extreme N Zaire.

Descriptive notes. 25 cm. Like *P. cryptoxanthus* with brown of throat extending more onto upper breast, underwing-coverts green, eye yellow (not red, as often stated). Immature duller and more yellowish, but difficult to distinguish from those of *P. meyeri* and *P. senegalus*.

Habitat. Forest-savanna mosaic, mixed lowland savanna and *Syzygium-Adina* riparian woodland, often near water; up to 1000 m.

Food and Feeding. Millet and pale yellow seeds in stomachs.

Breeding. Probably breeds from start of Aug in Zaire and Central African Republic.

Movements. Generally believed sedentary but with some nomadism and considerable daily displacements.

Status and Conservation. Not globally threatened. CITES II. The least known African parrot, assumed to be frequent to common in its poorly explored range, but this needs confirmation. Present but uncommon in Manovo-Gounda-St Floris National Park, Central African Republic. Rare, Sudan.

Bibliography. Bannerman (1953), Blancou (1939), Brickell (1985), Carroll (1988), Cave & Macdonald (1955), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Holyoak & Holyoak (1972), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1957, 1970), Nikolaus (1987), Snow (1978).

182. Red-bellied Parrot

Poicephalus rufiventris

French: Perroquet à ventre rouge **German:** Rotbauch-Mohrenkopf **Spanish:** Lorito Ventrirrojo
Other common names: (African) Orange-bellied Parrot

Taxonomy. *Pionus rufiventris* Rüppell, 1845, Shoa.

Probably belongs in superspecies with *P. meyeri*, *P. rueppellii*, *P. cryptoxanthus* and *P. crassus*. Two subspecies recognized.

Subspecies and Distribution.

P. r. pallidus van Someren, 1922 - E Ethiopia and Somalia.

P. r. rufiventris (Rüppell, 1845) - C Ethiopia to N Tanzania.

Descriptive notes. 25 cm; 120 g. Head, breast, upperparts and tail greyish brown; rump dusky blue; uppertail-coverts bluish green; belly and underwing-coverts orange red; thighs and vent green. Female has green belly and brown underwing-coverts. Immature like female, but with assumption of orange red in males. Race *pallidus* has paler grey on head and breast.

Habitat. Dry country, partial to *Commiphora* bush with baobabs, lowland *Acacia* short-grass savanna and *Acacia-Commiphora* thorn bush, riverine forest and bushland. Where sympatric with *P. meyeri*, uses open savanna.

Food and Feeding. *Ficus* fruits and *Acacia*

seeds taken, also ripe fruits of *Balanites aegyptiaca*, also *Cordia ovalis* and *Dalbergia melanoxylon*.

Breeding. May-Jun in Ethiopia; Nov, Jan and May in Somalia; possibly Jun-Jul in E Africa, where loosely colonial, a group of 6 pairs each occupying a single baobab 100–200 m apart over c. 30 ha in Feb.

Movements. Generally sedentary, but possibly moves out of NW Somalia in summer, as none seen Jun–Aug, and in Jul–Sept thought to move altitudinally up to 2000 m in pursuit of figs.

Status and Conservation. Not globally threatened. CITES II. Uncommon to common, Nechisar National Park, Ethiopia. Fairly common. E Africa, including Tsavo East National Park and Samburu Game Reserve in Kenya, and Mkomazi Game Reserve and Tarangire National Park, N Tanzania.

Bibliography. Archer & Godman (1937–1961), Ash & Miskell (1983), Berlioz & Roche (1963), Britton (1980a), Brown & Britton (1980), Clarke (1985), Dowsett & Forbes-Watson (1993), Duckworth *et al.* (1992), Friedmann (1930a), Fry *et al.* (1988), Harrison & Holyoak (1970), Holyoak & Holyoak (1972), Lack (1985), Lewis & Pomeroy (1989), Low (1993b), Mackworth-Praed & Grant (1957), Massa (1995), Norman (1991), Safford *et al.* (1993), Short *et al.* (1990), Snow (1978), Sweeney & De Dios (1993, 1994), Urban & Brown (1971), Zimmerman *et al.* (1996).

183. Senegal Parrot

Poicephalus senegalus

French: Perroquet youyou **German:** Mohrenkopf **Spanish:** Lorito Senegalés

Taxonomy. *Psittacus Senegalus* Linnaeus, 1766, Senegal.

Proposed race *mesotypus* from E end of range appears indistinguishable from, or only a clinal end of, nominate race. Two subspecies normally recognized.

Subspecies and Distribution.

P. s. senegalus (Linnaeus, 1766) - Gambia and Guinea-Bissau E to S Niger, N Cameroon and SW Chad. *P. s. versteri* Finsch, 1863 - NW Ivory Coast E to SW Nigeria, S of nominate *senegalus* but N of rain forest belt.

Descriptive notes. 23 cm; 120–161 g. Head grey; upperparts, breast and thighs green; belly yellow, shading to orange in centre; tail greenish brown; underwing-coverts yellow. Immature duller, with brownish head. All-yellow morphs reported, Gambia. Race *versteri* darker above, with deeper orange on centre of breast and upper belly.

Habitat. Any type of lowland savanna, but apparently favouring relatively open country with *Adansonia* or *Parkia filicoides* numerous, apparently also areas with borassus palms. Open woodland and cleared agricultural land with scattered trees, light orchard bush or isolated patches of heavier, almost closed-canopy woodland and wooded valleys; also in villages.

Food and Feeding. Fruits of *Ficus*, *Adansonia*, *Ximenia americana* and *Pterocarpus erinaceus*, seeds of *Parkia*, *Acacia albida*, *Khaya senegalensis*, *Vitex cienkowskii*, *Butyrospermum parkii* and *Sclerocarya birroea*, young buds of *Cassia*, flowers of *Melina*, plus cultivated crops such as millet, maize and peanuts.

Breeding. Jan–Oct in Gambia; Jun in Ghana; Aug in Niger; bird noted entering tree-hole in Nov, Burkina Faso; young fledging in Oct, Nigeria. Nest in hole commonly in larger branches of *Adansonia* or *Parkia*. Eggs 2–4; incubation c. 25 days; fledging in around 9 weeks.

Movements. Sedentary in places, e.g. Burkina Faso, but noted more numerous in rainy season, SW Niger, and a rainy season visitor (Sept–Dec) to parts of S Mauritania. Also seasonal, Apr–Dec, N Ghana, i.e. avoiding driest period. In Sierra Leone, known as vagrant to Freetown Peninsula with just 4 records, but reported by local bird-catchers to visit Kambia district in NW regularly in early dry season.

Status and Conservation. Not globally threatened. CITES II. Often abundant. Common, Boucle du Baoulé Biosphere Reserve, Mali. Breeds in W National Park, Niger. Common resident, Ghana and Nigeria, e.g. in latter's Falgore Game Reserve, although uncommon in Yankari Game Reserve and uncommon to frequent in Gashaka-Gumti Game Reserve (now National Park). Common in Bénoué Nord National Park, Cameroon.

Bibliography. Balança & de Visscher (1993), Bannerman (1953), de Bie & Morgan (1989), Brickell (1987), Callaghan (1982), Cheke & Walsh (1996), Claffey (1995), Coombes (1993), Crick & Marshall (1981), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fry *et al.* (1988), Gee (1984), Giraudoux *et al.* (1988), Gore (1990), Green (1990), Grimes (1987), Harris (1991), Harrison & Holyoak (1970), Holyoak, D.M. & Holyoak (1972), Holyoak, D.T. & Seddon (1990a), Koster & Grettenberger (1983), Lamarche (1980), Mackworth-Praed & Grant (1970), Muhé (1988), Petersen (1957), Radicke (1984), Schneider (1982), Sharland & Wilkinson (1981), Sheasby (1991), Snow (1978), Thiollay (1985), Thonnérieux *et al.* (1989), Wilkinson & Beecroft (1985).

184. Yellow-fronted Parrot

Poicephalus flavifrons

French: Perroquet à face jaune **German:** Schoapapagei **Spanish:** Lorito Carigualdo
Other common names: (African) Yellow-faced Parrot

Taxonomy. *Pionus flavifrons* Rüppell, 1845, Shoa.

Birds of SW Ethiopia formerly awarded race *auranticeps*, but racial segregation nowadays considered invalid. Monotypic.

Distribution. Ethiopia.

Descriptive notes. 28 cm; 140–205 g. Green, with forehead, crown and upper cheeks yellow, often washed orange; flight-feathers and tail dusky brown. Some yellow sometimes on wing edge and thighs. Female with less yellow, which is never washed orange. Immature yellowish olive where adult yellow.

Habitat. *Ficus-Acacia* riverine forest from 300 m, lowland subtropical humid forest, olive-*Podocarpus*-juniper forest, and *Hagenia* forest up to 3200 m. Penetrates well-wooded gardens in towns.

Food and Feeding. Poorly recorded, but presumably like other *Poicephalus* parrots. Observed feeding on ripe fruits of *Dovyalis abyssinica*, Nov.

Breeding. Unrecorded.

Movements. Sedentary, with occasional displacements, e.g. into Addis Ababa.

Status and Conservation. Not globally threatened. CITES II. Frequent to common, and considered commonest in the northerly, higher parts of its range. Present in Abijata-Shala Lakes and Bale Mountains National Parks, but elsewhere considered a minor crop pest and exposed to risk from future increases in chemical spraying to control damage by other bird species. No notable change in status in recent years.

Genus *ANODORHYNCHUS* Spix, 1824

185. Hyacinth Macaw

Anodorhynchus hyacinthinus

French: Ara hyacinthe **German:** Hyazinthara **Spanish:** Guacamayo Jacinto

Taxonomy. *Psittacus hyacinthinus* Latham, 1790, Brazil. Populations in S of range have been separated as race *maximiliani* but differences minute and clinal. Monotypic.

Distribution. NC to SC Brazil ranging into extreme NW Paraguay and E Bolivia; formerly present in Amapá, N Brazil, and possibly still so.

Descriptive notes. 100 cm; 1435-1695 g. Cobalt blue throughout, more violet on wings; undersides of flight-feathers and tail grey; bare orbital ring and strip at base of lower mandible yellow. Immature has shorter tail and paler bare skin.

Habitat. Edge of tropical moist lowland forest, palm savannas, open dry woodland with gallery forest and *Mauritia* palm stands, the critical factors evidently being presence and abundance of appropriate palm foodplants.

Food and Feeding. Dependent on small number of palm species, using different species in different areas: in Amazon region

Maximiliana regia, *Orbignya martiana* and *Astrocaryum*; in the Pantanal *Scheelea phalerata* and *Acrocomia totia*; in dry NE of range *Attalea funifera* and *Syagrus coronata*, where most foraging done on ground. Other fruits also sometimes taken, and even snails *Pomacea*.

Breeding. Jul-Dec. Nest in hole in tree in lower Amazon and Pantanal, usually one of only three species in latter (and chiefly *Sterculia striata*), since only these reach sufficient size; otherwise dead palm trees and stubs commonly provide sites; in NE Brazil nests in cliff. Eggs 2, sometimes 3; incubation 27-30 days; nestling period generally 105-110 days. Usually only one young fledges, although success appears to vary between years.

Movements. Seasonal displacements over large distances are strongly indicated by fragmentary evidence from Lower Amazon, apparently geared to plant phenology.

Status and Conservation. **VULNERABLE.** CITES I. This species was reduced to an estimated 3000 birds by massive illegal trade in the period 1970-1990, with possibly as many as 10,000 being taken from the wild in the 1980's alone. In 1987 the species was placed on Appendix I of CITES, but for a time this only stimulated greater demand. In the 1990's several long-term studies of the species have started, in part coupled with conservation initiatives, often involving ecotourism, environmental education and nest-box deployment, at certain ranches in the Pantanal. However, local trapping for feathers and food may persist, as well as destruction of nest-sites either for farming or to obtain birds, and indeed general habitat loss throughout the species's range continues to decrease its survival prospects.

Bibliography. 186. Indigo Macaw

Anodorhynchus leari

French: Ara de Lear **German:** Learara **Spanish:** Guacamayo de Lear
Other common names: Lear's Macaw

Taxonomy. *Anodorhynchus leari* Bonaparte, 1856, no locality, presumed to have come from Brazil. May form a superspecies with *A. glaucus*. Monotypic.

Distribution. Interior NE Brazil.

Descriptive notes. 75 cm; 940 g. Metallic blue throughout, slightly tinged green, richer on wings, slightly fuscous on breast; bare orbital ring and semi-circular patch at base of lower mandible yellow.

Habitat. *Caatinga* thornscrub vegetation with stands of licuri palm (*Syagrus coronata*) and pastures, plus the proximity of sandstone cliffs for nesting and roosting.

Food and Feeding. Predominantly licuri palm nuts; also fruits of *Jatropha pohliana*, *Spondias tuberosa*, *Dioclea*, flowers of *Agave*, seeds of *Melanoxylon*; maize also taken when ripening.

Breeding. Oct-Jan. Nest in fissure in cliff. Clutch size unknown but 2 offspring repeatedly recorded fledging from nests; incubation in captivity lasts 28 days or more.

Movements. Apparently sedentary, with birds tied year-round to lands reachable from their accustomed nesting and roosting cliffs.

Status and Conservation. **CRITICALLY ENDANGERED.** CITES I. A BirdLife "restricted-range" species. Although known since mid-19th century from traded birds, wild population only discovered in 1978 when judged to consist of 60 birds, not all mature. Several new smaller populations have now been discovered, and in Jul 1994 altogether 118 birds were counted and the total popula-

tion was estimated at 140 birds. The species may always have been rare, hanging on as a relict, but the activities of man for possibly several hundred years have doubtless affected it adversely: clearance and non-regeneration of licuri palm stands as a consequence of stock-raising is probably the greatest and most enduring problem, since the original area covered by this palm was 250,000 km², while today the range of the macaw is confined to roughly 4000 km². Hunting for food was evidently also serious in the past. Trapping for trade, although illegal, is an ever-present danger: at least 19 birds probably stolen from the wild population

in 1996, a level of predation that would clearly obliterate the tiny wild population within under ten years; newly discovered populations are scattered in a remote area that appears difficult to police effectively. There are various initiatives to secure the management of local farmland and to warden colonies to minimize risks of disturbance and trapping. Part of the population occurs in the Raso da Catarina Ecological Station, but this is not in itself a guarantee of security.

Bibliography. Beissinger & Snyder (1992), Bish (1985), Brandt & Machado (1990), Cavalcanti (1988), Clinton-Eitnien (1981b), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Decoteau (1982), Forrester (1993), Freud (1980a), Harrison & Holyoak (1970), Hart (1992, 1995), King (1978/79), Low (1972, 1994b, 1997g), Munn (1995b), Reynolds (1993, 1995, 1997), Ridgely (1981), Seitre (1990), Shuker (1993), Sick (1979a, 1979b, 1981a, 1985, 1993), Sick & Teixeira (1980, 1983), Sick, Gonzaga & Teixeira (1987), Sick, Teixeira & Gonzaga (1979), Snow (1985), Stotz *et al.* (1996), Vieillard (1979), Voous (1965), Wege & Long (1995), Whitney (1996), Yamashita (1987), Yamashita & Valle (1993).

187. Glaucous Macaw

Anodorhynchus glaucus

French: Ara glauque **German:** Türkisara **Spanish:** Guacamayo Glauco

Taxonomy. *Macrocerus glaucus* Vieillot, 1816. South America between lat. 27° and 30° S...on the banks of the Paraná and Uruguay Rivers.

May form a superspecies with *A. leari*. Monotypic.

Distribution. E Paraguay, SE Brazil, W Uruguay and N Argentina.

Descriptive notes. 72 cm. Dull greenish blue; head and neck suffused greyish; bare orbital ring and semi-circular patch at base of lower mandible yellow; underside of tail grey. Immature undescribed.

Habitat. Lightly wooded grassland, marshes and river borders with good stands of palms and in particular yatay or chatay (*Butia yatay*).

Food and Feeding. Palm nuts, almost certainly predominantly those of *Butia yatay*.

Breeding. Dec-Jan. Nest in hole in cliff, e.g. in riverbank, but also in tree. Eggs reportedly two.

Movements. No certain information; the species was described as sedentary by one observer in the early nineteenth century, but a coastal island site in Santa Catarina, reported only once, is so anomalous that it may have been a seasonally visited area.

Status and Conservation. Almost certainly **EXTINCT.** CITES I. There have been only two moderately acceptable reports in the wild this century, and rumours of surviving populations and birds in private collections have either been disproved or remain unsubstantiated; possible sighting reported from Paraguay, 1997. The similarity of the species to *A. leari* has made it possible to work out the most probable food (yatay palm) within its known range: this palm, being an indicator of good soils, was a prime target for clearance by early colonists, and great areas of palm stand either were cut down or failed to regenerate owing to cattle-grazing. Other habitat destruction may also have been important, e.g. widespread loss of gallery forests. Substantial use of the species for food must have been greatly facilitated by its colonial cliff-nesting habit.

Bibliography. Beissinger & Snyder (1992), Belton (1984), Canevari *et al.* (1991), Chebez (1986a, 1994), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Decoteau (1982), Hayes (1995), King (1978/79), Low (1972, 1994b), Nores & Yzurieta (1994), Orfila (1936), Ridgely (1981), Shuker (1993), Sick (1969, 1985, 1993), Sick & Teixeira (1979), Smith, G.A. (1991b), Snow (1985), Stotz *et al.* (1996), Straube (1988), Vieillard (1979), Yamashita & Valle (1993), Zotta (1944).

Genus *CYANOPSITTA* Bonaparte, 1854

188. Spix's Macaw

Cyanopsitta spixii

French: Ara de Spix **German:** Spixara **Spanish:** Guacamayo de Spix
Other common names: Little Blue Macaw

Taxonomy. *Sittace Spixii* Wagler, 1832, Joazeiro, Rio São Francisco, Brazil.

Occasionally placed in *Ara*. Monotypic.

Distribution. N Bahia (E Brazil).

Descriptive notes. 55-57 cm; 296-400 g (captivity). Crown pale greenish blue; bare mask-like area around eye to upper mandible blackish grey; cheeks to ear-coverts light grey, shading to blue of rest

Nest in hole in caraiba and, by report, braúna. Eggs probably 2-3, although in captivity 4 laid; again in captivity, incubation 26 days, and nestling period two months, with a dependence period of 3 months after that.

Movements. Reports of the species from other habitats and areas are mostly likely to be misidentifications, but some nomadism may have occurred in cases where nesting habitat was cleared and birds, unlimited by food availability, wandered in search of alternative areas to breed in. Moreover, some wandering in response to rainfall appears to have taken place, with (e.g.) birds absent from their known breeding area from Dec 1986 to Mar 1987, reappearing when rains began. The single surviving wild bird sometimes disappears for days or even weeks from its favoured area.

Status and Conservation. CRITICALLY ENDANGERED. CITES I. A BirdLife "restricted-range" species. Although known to science since 1824 and fully protected by Brazilian law since 1967, the species was only rediscovered in the wild in 1985, when just five birds, including two pairs, were located at Melância Creek near Curaçá, N Bahia. Trappers had been active at the site for some 15 years, removing at least 23 birds and possibly as many as 40, and by 1988 appeared to have removed the last five. However, one wild survivor was located in 1990, when it was realized that while trapping was the proximate cause of the species's rarity, the ultimate cause was the almost total loss of caraiba woodland, its nesting habitat, of which only 30 km² appeared to remain. The Brazilian nature conservation authority, IBAMA, established a Permanent Committee for the Recovery of Spix's Macaw in 1990, and this has involved various interested parties including most holders of captive birds, plus representatives of certain international nature conservation bodies. Attempts have been made to improve captive breeding performance by moving birds between facilities, and there has been a steady growth in the number of captive birds to over 30, although most (and probably all) are very closely related to one another. In 1995, after tests on feathers to confirm the sex (male) of the wild bird, a captive wild-caught female was released to join it. However, the wild bird had paired with a solitary *Propyrrhura maracana*, and although the released female met up with the male they did not form a bond, possibly because of the *Propyrrhura*, and in due course the female disappeared. In mid-1996 the male was still alive.

Bibliography. Anon. (1995c, 1995f, 1995h), Arndt *et al.* (1986), Beissinger & Snyder (1992), Brack (1987), Cavalcanti (1988), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Decoteau (1982), Forrester (1993), Griffiths & Tiwari (1995), Hämmerli (1991), Harrison & Holyoak (1970), Juniper (1990a, 1990b, 1991, 1997), Juniper & Yamashita (1990, 1991), Keller (1987, 1992), King (1978/79), Low (1972, 1994b, 1997g), Margolis (1996), da Ré (1995), Reynolds (1993), Ridgely (1981), Roth (1985, 1986, 1987a, 1987b, 1988a, 1988b, 1989b, 1990), Sick (1969, 1985, 1993), Silva (1990, 1991a, 1994a, 1994c), Smith, G.A. (1991a), Snow (1985), Sojer (1989), Sojer & Wirth (1989), Stotz *et al.* (1996), Sweeney (1994d, 1995c, 1996d), Thomsen & Munn (1988), Vaughan (1993), Waugh (1996a, 1996b), Wege & Long (1995), Whitney (1996).

Genus *ARA* Lacépède, 1799

189. Blue-and-yellow Macaw

Ara ararauna

French: Ara bleu **German:** Ararauna **Spanish:** Guacamayo Azulamarillo
Other common names: Blue-and-gold Macaw

Taxonomy. *Psittacus Ararauna*, Linnaeus, 1758, South America = Pernambuco. Monotypic.

Distribution. E Panama through Colombia E to S Venezuela, the Guianas and Brazil, and S to W & E Ecuador, E Peru and NE Bolivia; formerly occurred on Trinidad, and apparently also in Paraguay and N Argentina. Also listed for W Ecuador, where probably extinct.

Descriptive notes. 86 cm; 995-1380 g. Forehead to mid-crown dull green shading into blue on rest of upperparts, wings and tail; bare face white with thin dark feathered transverse lines, the lowest of which loops down and broadens as blackish green chinstrap; ear-coverts, sides of neck and rest of underparts strong yellow except vent pale blue; underside of tail gold edged dusky; underwing-coverts yellow. Immature similar.

Habitat. Seasonally flooded *várzea* forest and gallery forest, *Mauritia* palm stands in savanna, and, in NW of range, deciduous forest away from water; lowlands to only 500 m in

most of range, occasionally to 1500 m in Peru.

Food and Feeding. Seeds of *Spondias*, *Terminalia*, *Hura*, *Enterolobium*, *Inga*, *Parkia*, *Platypodium*, nectar of *Quararibea*, flowers of *Combretum*, fruit and/or petioles of *Ficus*, pulp of *Sloanea*, *Schwartzia*, *Brosimum*, *Soroea*, aril of *Otoba*, leaves of *Iriarte*, mesocarp of *Scheelea* and *Pouteria*, and undetermined parts of *Mauritia*; *Maximiliana* palm nuts in Surinam.

Breeding. Evidence of breeding Dec-Feb in Colombia, Jan-Mar in Surinam, and Apr-May on Trinidad; in Guyana, eggs laid around Feb, cycle lasting to Jun; in Peru eggs laid Nov-Jan, cycle completed generally by Apr. Nest in hole high in dead *Mauritia* or other palm. Eggs 1-3. In one study, of 17 nestlings recorded in 14 nests, 10 (59%) fledged, 3 (18%) died of malnutrition or related diseases, and 4 (24%) were killed by predators.

of plumage, slightly glaucous on belly and vent; wings and tail darker blue. Immature has bare facial area whitish grey, plumage darker blue.

Habitat. Gallery woodland dominated by caraiba (*Tabebuia caraiba*) trees within the *caatinga* dry scrub zone, dominated locally by the euphorbs *Jatropha* and *Cnidocolus* along with *Caesalpinia*, *Ziziphus* and various cacti such as *Cereus*, *Pilocereus* and *Opuntia*.

Food and Feeding. Seeds of *Jatropha* and *Cnidocolus*, fruits of *Ziziphus* and *Maytenus*, fruits and/or seeds of braúna (*Melanoxylon*).

Breeding. Nov-Mar, variable with rainfall.

Movements. Seasonal foraging may take birds into semi-open country (in Colombia this typically happens in wet season), and such movements appear to be responsible for records of the species from Paraguay.

Status and Conservation. Not globally threatened. CITES II. Common still in much of range, with a density of 1 pair/km² in Manu National Park, Peru. However, less numerous at edges of range, and declining with habitat loss in many of these peripheral areas; thus extinct on Azuero Peninsula, Panama, and probably extinct in W Andes, Ecuador, and at great risk in W Andes, Colombia; however, still common in Los Katíos National Park in NW Colombia in 1989. Around 1980 only around 10 birds remained in the Nariva Swamp, Trinidad, and these are now gone, in large part owing to the taking of young from nests. In SE Brazil the species became extinct by 1960's except for relict population in Morro do Diabo State Forest, São Paulo, and in SW Brazil there is evidence for substantial local decrease in numbers, for reasons unclear. Many thousands exported annually, chiefly from Bolivia and Guyana, in late 1970's, and although still common in former in early 1980's there were strong fears for its long-term survival there. Bolivia exported 18,350 in the four years 1981-1984 after which trade was banned, but Guyana continued to export over 2000 birds annually, 1985-1990, prohibiting further trade in 1993. Areas depleted by intensive trapping may recover numbers fairly rapidly, but local extinction in Orinoco Delta within 10 years predicted from relentless removal of young from nests, and hunting pressure has caused a considerable decrease in French Guiana, where only a few hundred were believed to survive in the 1980's; in Surinam it is still a gamebird with open season 15 Jul-31 Dec, and as a consequence now lost from Surinam R basin. In E Peru, where suitable nest-sites appear to limit the population, nesting habitat has successfully been created by decapitating *Mauritia* palms.

Bibliography. Abramson (1993b), Anon. 190. Blue-throated Macaw

Ara glaucogularis

French: Ara canindé **German:** Blaukehrlara **Spanish:** Guacamayo Barbazul
Other common names: Caninde/Wagler's Macaw

Taxonomy. *Ara glaucogularis* Dabbene, 1921, Santa Cruz de la Sierra, Department of Santa Cruz, Bolivia.

Taxonomic status long disputed, largely because species was unknown in wild to ornithologists until very recently; was considered probably an aberrant form of *A. ararauna*, but the two are now known to occur sympatrically without interbreeding. In past, present species has erroneously been named *A. canindé*, but this name is probably a synonym of *A. ararauna*. Monotypic.

Distribution. N Bolivia.

Descriptive notes. 85 cm; 600-800 g. Very similar to *A. ararauna*, but lighter and thinner tailed, crown all blue, and bare facial patch (pinkish around base of bill) almost totally obscured by thick blue feather lines merging into blue lower cheek, chin and throat. Immature has darker blue on throat.

Habitat. Seasonally inundated savanna with groves of *Attalea phalerata* and *A. princeps* palms, scattered *Acrocomia* and *Copernicia* palms, and small slightly raised patches of low tropical forest dominated by *Scheelea* and *Acrocomia* palms and large *Tabebuia impetiginosa* trees. Occurs in lowlands at 200-

300 m, on occasion near human habitation.

Food and Feeding. Mesocarp of fruits of *Attalea* and *Acrocomia* palms, occasionally opening unripe *Attalea* nuts to drink liquid within.

Breeding. Oct/Nov-Mar. Nest in hole in *Acrocomia* or *Attalea* palm or tall *Tabebuia*; in Nov 1996, nest found in live deciduous tree, probably *Calycophyllum*. In captivity: 2-3 eggs; incubation 26-28 days; nestling period 90-94 days.

Movements. No information.

Status and Conservation. ENDANGERED. CITES I. A BirdLife "restricted-range" species. This bird has always been very rare and until 1992 was known by skins from uncertain localities and captive specimens. Although 28 birds were discovered in 1992, the possible total in three areas of N Bolivia may be only 100 individuals, well short of the 500-1000 suggested in early 1980's. Seen in flocks of up to 5 birds, never in large ones like some macaw species; in occupied areas, outnumbered by *A. ararauna* by factor of 20, and may suffer competition from this larger congener. The principal danger at present is from trapping for trade, e.g. 6 wild-bred birds stolen from Santa Cruz Zoo in Dec 1996; 390 birds recorded in international trade in period 1981-1992, most in 1981-1984; CITES I since 1983, and additional Bolivian legislature in 1984 and 1986. Also significant is agriculture, as all populations located to date are on ranchland: burning to improve pasture destroys potential nesting trees and may reduce food supplies; cattle too cause serious damage to vegetation. Current conservation initiatives include discussions with local ranchers and also with schoolchildren in order to enlist local support to save the species; requirements include more exhaustive census work and also research into biology and ecology.

Bibliography. Abramson (1993b), Anon. (1997a), Beissinger & Snyder (1992), Brack *et al.* (1995), Canevari *et al.* (1991), Chebez (1987a), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Duffield & Hesse (1997), Freud (1993c), de Grahl (1985), Hayes (1995), Hayward (1983), Hesse (1993, 1997), Ingels *et al.* (1981), Jordan & Munn (1993), Kiessling (1985), King (1978/79), Lanning (1982), Leibfarth (1988), Low (1972, 1994b), Morvan *et al.* (1993, 1995), Munn & Munn (1993), Nores & Yzurieta (1984, 1994), Remsen & Traylor (1989), Remsen *et al.* (1986), Ridgely (1981), Riviere *et al.* (1986), Stotz *et al.* (1996), Sweeney (1994b, 1996c, 1997c), Waugh (1996b), Wege & Long (1995), Whitney (1996).

191. Military Macaw

Ara militaris

French: Ara militaire **German:** Soldatenara **Spanish:** Guacamayo Militar

Taxonomy. *Psittacus militaris* Linnaeus, 1766, no locality, Colombia suggested. Sometimes treated as conspecific with *A. ambiguus*, but in spite of evidence of interbreeding the characters of the two forms are consistently different over their respective ranges. Three subspecies recognized.

Subspecies and Distribution.

A. m. mexicana Ridgway, 1915 - Mexico.

A. m. militaris (Linnaeus, 1766) - NW Venezuela, Colombia, E Ecuador and N Peru.

A. m. boliviana Reichenow, 1908 - Bolivia and N Argentina.

Descriptive notes. 70-71 cm; 972-1134 g. Forehead red; bare patch on face extending over eye white (often flushing pinkish-red) with dark transverse feather lines; rest of crown, nape and body green, except olive-yellow on throat and pale blue on lower back, rump and tail-coverts; wings with olive tone, flight-feathers mostly blue above, olive-yellow below; tail blue above, with red at base, olive-yellow below. Immature similar. Race *mexicana* slightly larger; *boliviana* has indistinct brown throat patch, spreading onto upper breast.

Habitat. Relatively dry montane evergreen and tropical deciduous forest, gallery woodland and

pine-oak formations, 600-2600 m, seasonally in some places penetrating humid forest, thorn forest and other habitats in lowland areas. Local presence dictated by preference for roost- and nest-sites in cliffs.

Food and Feeding. *Jessenia bataua* palm, *Melia azedarach* fruit, *Ficus*.

Breeding. Reportedly from Mar in Mexico, but other evidence indicates as late as Jun-Jul. No information elsewhere in range. Nest in hole in tree. In Mexico even holes fashioned by the near-extinct or extinct Imperial Woodpecker (*Campephilus imperialis*); also in cliffs, and formerly on rocky inshore islets off Acapulco. Eggs 2-3.

Movements. In Colombia regularly crosses E Andes from Huila to Caquetá, and then present in Cueva de los Guácharos National Park, May-Aug. In Peru birds (used to) cross from E slopes to an area of forest on W. Sept-Oct, to feed on particular fruits, thereby crossing large stretches of *puna* grassland. Birds also extend down into lower-lying habitats at certain seasons, e.g. dense thorn forest in dry season, Nov-Jun, W Mexico.

Status and Conservation. **VULNERABLE.** CITES I. In Mexico, uncommon to frequent in N part range, but possibly extinct in S, largely through trade. Reintroduction being attempted, Guatemala. Highly threatened in restricted Venezuelan range by combination of habitat loss and trade pressure; small populations are resident in Henri Pittier and Guatopo National Parks. Fairly common on N slope of Santa Marta massif but sporadic elsewhere, Colombia. Very few recent records, Ecuador. Uncommon and becoming rarer, N Peru, but as many as 50-60 birds seen per day in the Salvación and Atalaya areas of Manu National Park, 1994. Up to 60 recorded recently near Amboví National Park, Bolivia, but in Argentina the species is now extremely rare and on the verge of extinction.

Bibliography. Abramson (1993b), Binford (1989), Canevari *et al.* (1991), Chebez (1991), Collar (1996), Collar *et al.* (1994), Davies *et al.* (1994, 1997), Davis (1986), Desenne & Strahl (1991, 1994), Fernández-Badillo *et al.* (1994), Fjeldså & Krabbe (1990), Fjeldså *et al.* (1987), Gardner (1972), Haffer (1975), Hilty & Brown (1986), Howell & Webb (1995a), Inskipp *et al.* (1988), Low (1972, 1994b, 1997g), Machado de Barros (1995), Meyer de Schauensee & Phelps (1978), Munn (1988), Nore & Yzurieta (1994), O'Neill (1981), Parker *et al.* (1982), Pulido (1991), Ridgely (1981), Rowley (1984), Schaldach (1963), Stotz *et al.* (1996), Vansteenkiste (1997), Whitney (1996), Wille (1992), Zimmer (1930).

192. Great Green Macaw

Ara ambiguus

French: Ara de Buffon

German: Bechsteinara

Spanish: Guacamayo Ambiguo

Other common names: Buffon's Macaw

Taxonomy. *Psittacus ambiguus* Bechstein, 1811, north-western Colombia.

Sometimes treated as conspecific with *A. militaris*, but in spite of evidence of interbreeding the characters of the two forms are consistently different over their respective ranges. Two subspecies recognized.

Distribution.

A. a. ambiguus (Bechstein, 1811) - E Honduras and Nicaragua through Costa Rica and Panama to NW Colombia.

A. a. guayaquilensis Chapman, 1925 - W Ecuador.

Descriptive notes. 85-90 cm; 1265-1430 g. Very similar to *A. militaris* but larger with larger bill, notably paler (lime) green on head and upper wing-coverts, paler blue on lower back to uppertail-coverts, and tail longer and with more orange-red; in old birds, especially females, the black lines of the face turn red, a tendency not noted in *A. militaris*. Immature duller, more olive. Race *guayaquilensis* has a smaller bill.

Habitat. Humid lowland evergreen forest and intervening tracts of partially cleared terrain, up to 1000 m; in Colombia in wetter areas than *A. militaris*, but in Ecuador the species also

extends into deciduous forest.

Food and Feeding. Seeds of *Dipteryx panamensis* are highly important during the breeding season, but other seeds and fruit are taken, including the very hard-shelled *Lecythis costaricensis*.

Breeding. Dec-Apr or later in Costa Rica; May-Oct in Ecuador. Nest is hole in tree, in one case a dead *Cavanillesia platanifolia* in Ecuador, but large *Dipteryx panamensis* apparently preferred in Costa Rica. Lays 2-3 eggs, captive birds rarely 4; in captivity, incubation by female only around 29 days, nestling period about 11 weeks.

Movements. Very poorly understood, but in Costa Rica birds range widely over Caribbean slope, perhaps tracking fruiting *Dipteryx*; concentrations appear on the coast, Oct-Dec, then are thought to move inland to breed, thereafter dispersing to other parts of the coastlands.

Status and Conservation. **VULNERABLE.** CITES I. Retreating in response to habitat loss throughout its range, and sensitive to habitat disturbance; perhaps NW Nicaragua and Colombia's Baudó Mountain foothills alone hold tracts of sufficiently extensive primary forest for its long-term sur-

vival. In Honduras its stronghold is the Río Plátano Biosphere Reserve, and in Panama it is fairly common in the Darién Biosphere Reserve. In Costa Rica the technology has been developed to process the super-hard timber of *Dipteryx* trees, so the species is now in crisis there. Numbers in Central America are much lower than the total of 5000 estimated for *Ara macao*, so situation clearly very serious. In N Ecuador (subspecies uncertain) the total population, located in and around Cotacachi-Cayapas Ecological Reserve, may only be 50-100 birds. Race *guayaquilensis* long considered threatened and now critically so, but with efforts being made to protect it in the 20 km² Cerro Blanco Forest Reserve in Guayas; there are also records from Machalilla National Park.

Bibliography. Abramson (1993b), van den Berg & Bosman (1984), Berg & Horstman (1996), Bjork & Powell (1995), Carriker (1910), Collar (1996), Collar *et al.* (1994), Fjeldså *et al.* (1987), Gale (1983), Haffer (1975), Hilty & Brown (1986), Horstman (1995, 1996), King (1978/79), Low (1972, 1994b, 1995b, 1997g), Meyer de Schauensee (1949), Monroe (1968), Müller (1997), Pfeffer (1997), Ridgely (1981), Ridgely & Gwynne (1989), Slud (1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Thorn (1991), Waugh (1995), Wetmore (1968), Whitney (1996).

193. Scarlet Macaw

Ara macao

French: Ara rouge

German: Arakanga

Spanish: Guacamayo Macao

Taxonomy. *Psittacus Macao* Linnaeus, 1758, South America.

Two subspecies recognized.

Subspecies and Distribution.

A. m. cyanoptera Wiedenfeld, 1995 - SE Mexico to Nicaragua.

A. m. macao (Linnaeus, 1758) - Costa Rica, Panama and N & E Colombia (recent record from Nariño), E through Venezuela and the Guianas to C Brazil, and S to E Ecuador, E Peru and NE Bolivia.

Descriptive notes. 84-89 cm; 900-1490 g. Head and most of body red; large bare facial area extending round eye white; bill whitish above, blackish below; greater and median wing-coverts yellow edged with green; flight-feathers mainly blue; underwing mostly red; back, rump and tail-coverts pale blue; tail red tipped blue. Immature has shorter tail. Race *cyanoptera* larger, with yellow wing-coverts tipped blue.

Habitat. Largely in humid *terra firme* lowland evergreen forest and gallery woodland in savannas, often in vicinity of exposed river banks and clearings with big trees, and some-

times entering drier formations; tends to be confined to riverine forest in Guianas and more open deciduous or pine forest in Central America, sometimes roosting in mangroves; up to around 500 m, ranging at least formerly up to 1000 m in Central America.

Food and Feeding. Seeds of *Jacaranda*, *Dialium*, *Sclerolobium*, *Hymenaea*, *Caryocar*, *Licaria*, *Hevea*, *Guarea*, *Piptadenia*, *Porouma*, *Euterpe*, *Cedrela*, *Hura*, *Terminalia*, *Eschweilera*, *Sapum*, flowers/nectar of *Virola*, *Erythrina*, *Ochroma*, *Quararibea*, *Combretum*, leaves of *Laetia*, *Aspidosperma*, *Licania*, *Schizolobium*; pulp/ fruit of *Inga*, *Micropholis*, *Sterculia*, *Bursera*, *Ficus*, *Scheelea*, *Spondias*, *Dipteryx*, *Borismene*, *Anomospermum*, *Sorocea*, *Pseudolmedia*, *Ampelocera*, fruits and/or seeds of *Anacardium*, *Bernoullia*, *Brosimum*, *Enterolobium*, *Pithecellobium*, *Bytneria*, *Leonia*, *Couma* and *Goupia*; fruit, seeds, bark and leaves of *Ceiba*; fruit, seeds and flowers of *Tabeuia*, arils of *Virola* and *Cupania*, sap of *Clarisia*; in Brazil *Bertholletia*, *Lecythis* and *Syagrus* fruit appear to be favoured. In Central America birds noted to eat *Pinus caribaea* seeds, crushing the cones and dropping a shower of scales.

Breeding. Mar in Mexico; Apr in Nicaragua; Oct-Apr in Costa Rica, with flying young noted as early as Feb on Coiba I, Panama; evidence for Mar in French Guiana; Oct-Mar in C Brazil; Nov-Apr in Peru. Nest in large natural cavity 7-40 m up in tall tree, commonly in *Iriarthea* palms in Peru, where competition with *A. chloroptera* prevents use of *Dipteryx* and other hardwoods; in Costa Rica *Schizolobium* and *Ceiba* preferred. Eggs 1-4; incubation 24-28 days; nestling period 14 weeks. In one study, 9 out of 14 nests successfully produced one or more young; of the 21 nestlings involved, 10 (48%) fledged, 4 (19%) died of apparent malnutrition, and 7 (33%) were predated. In Costa Rica recruitment rates, 1990-1992, varied from 6.2% to 10.2%.

Movements. Seasonal movements in search of fruit occur, but pattern not determined other than that in Colombia in "summer" it penetrates semi-arid forest, and that it was a winter visitor in very large numbers, now all gone, to Pacific swamp and tropical deciduous forest in Oaxaca, Mexico.

Status and Conservation. Not globally threatened. CITES I. Common over much of extensive range where habitat remote from human disturbance, with a density of 1 pair/km² in Manu National Park, Peru. However, in Central America (where once revered as an oracle of the sun) the race *cyanoptera* only now survives in the Lacandon Forest, Mexico; it is now mainly confined to one area in Belize; it is extinct in most of Guatemala save the Petén; it is extinct in El Salvador; it is extinct or virtually so on the Pacific slope of Honduras and Nicaragua, although a relict population survives on the Cosigüina Peninsula in the latter; while on the Caribbean side 1000-1500 birds may survive in Honduras centred on Depto. Gracias A Dios (a good number are protected within Río Plátano Biosphere Reserve), and a population persists in eastern Nicaragua; altogether the total number of this subspecies is estimated at c. 4000. Habitat destruction and considerable trapping pressure, including for household pets locally, are responsible for this situation. The nominate race has also suffered substantial declines in settled and developing areas, and relict populations survive in Costa Rica, the best protected being in Corcovado National Park, and in Panama the stronghold is now Isla Coiba owing to its status as a penal settlement, birds at the only other site (Azuerro Peninsula) suffering from habitat loss and persecution by Indians using their feathers; the total Central American population of nominate birds may be only c. 1000. In French Guiana the species is less common than *A. chloroptera*, with most in coastal forests. Conservation initiative in Carara Biological Reserve, Costa Rica, involves education programmes for local communities, visitors and guards, community development with ecotourism promotion, and ongoing intensive biological study. Provision of nestboxes made from *Iriarthea* palm stems has been highly successful in improving reproductive output of the species in Peru, where the main constraint appears to be nest-site availability.

Bibliography. Abramson (1993b), Binford (1989), Bradshaw *et al.* (1995), Clinton-Eitner (1981a, 1991), Desenne (1994), Desenne & Strahl (1991, 1994), Fragosó (1985), González-García (1993), Greiser (1995), Haverschmidt & Mees (1994), Hebert (1992), Hilty & Brown (1986), Howell & Webb (1995a), Low (1972, 1997g), Lowery & Dalquest (1951), Marineros & Vaughan (1995), McLoughlin & Burton (1970), Meyer de Schauensee & Phelps (1978), Monroe (1968), Müller-Bierl (1986), Munn (1988), Nycander *et al.* (1995),

(1991d), Snyder (1966), Stiles & Skutch (1989), Stotz *et al.* (1996), Terborgh *et al.* (1990), Thorn (1991), Tostain *et al.* (1992), Vaughan & Liske (1991), Vaughan *et al.* (1991), Volk & Volk (1983), Wetmore (1957, 1968), Whitney (1996), Wiedenfeld (1994).

194. Red-and-green Macaw

Ara chloroptera

French: Ara chloroptère **German:** Grünflügelara **Spanish:** Guacamayo Aliverde
Other common names: Green-winged Macaw

Taxonomy. *Ara chloropterus* G. R. Gray, 1859, no locality. Original spelling has been taken as evidence that species name was created as a masculine noun; however, at least as likely to be a *lapsus calumi*, and long-standing feminine ending should thus be retained. Monotypic.

Distribution. E Panama through lowland Colombia, Venezuela, the Guianas and Brazil S to Paraguay and W to E Ecuador, E Peru and NE Bolivia; formerly in N Argentina.

Descriptive notes. 90-95 cm; 1050-1708 g. Very similar to *A. macao* but green in wing instead of yellow, red feathered lines on bare face, flight-feathers above mostly pale blue, and larger, with bill proportionately larger. Immature has shorter tail and replaces black on bill with grey.

Habitat. Humid lowland evergreen forest, generally up to 500 m, but also penetrating tropical deciduous forest and gallery woodland in savannas and llanos, and even undisturbed *caatinga* vegetation; favours hilly areas in Panama, where reaches to 1500 m.

Food and Feeding. Seeds of *Jacaranda*,

Tetragastris, *Sclerolobium*, *Hymenaea*, *Copaifera*, *Caryocar*, *Hevea*, *Eschweilera*, *Guarea*, *Abuta*, *Euterpe*, *Maximiliana*, *Micropholis*, *Sterculia*, *Spondias*, *Terminalia*, *Sapium*, *Croton*,

Parkia, pulp of *Inga*, *Quararibea*, *Rheedia*, *Eperua*, *Dipteryx*, *Schwartzia*, *Borismene*, *Sorocea*, *Mauritia*, fruits of *Endopleura*, *Bertholletia*, endosperm of *Scheelea*, arils of *Virola*, leaves of *Erythrina*.

Breeding. Nesting or prospecting in Dec, Surinam; Nov-Apr in Peru; evidence of nesting from Jan in C Brazil. Nest in hole in tree, in E Peru preferred species being *Dipteryx* or *Iriarthea*; in sandstone cliffs at two sites in Bolivia, in natural cavity high in cliff, NE Brazil, and birds observed digging in river cliffs in S Brazil. Eggs 2-3. In one study, 7 out of 16 nests successfully produced one or more young; of the 25 nestlings involved, 10 (40%) fledged, 9 (36%) died of apparent malnutrition, and 6 (24%) were predated.

Movements. No information. Birds are reportedly commoner in the dry season. Mato Grosso, and records in Argentina may always have been of wanderers.

Status and Conservation. Not globally threatened. CITES II. Generally uncommon, pairs frequently solitary and dispersed. Has declined at edges of range, and usually disappears early from areas disturbed or settled by man. Very uncommon, Panama, where at risk from trade. In steep decline, W Colombia. Heavily persecuted for trade, Venezuela, but little habitat loss as yet. Uncommon in Guyana, but most widespread macaw in Surinam and French Guiana, but greatly reduced in latter through uncontrolled hunting but still commoner there than *A. macao* (in contrast to pattern elsewhere). Under great pressure in E parts of C Brazil from both habitat loss and in particular taking of nestlings for trade, and now extinct in SE Brazil, where formerly common, except for remnant population in Morro do Diabolo State Forest, São Paulo. Apparently a steep decline in Ecuador in 1970's, but still fairly common, Peru, with a density of 1 pair/km² in Manu National Park. Common in *campos cerrados*, Paraguay, elsewhere uncommon to rare. Few records in Argentina since 1917, possibly escapes. Most of the average 1962 birds in international trade each year in 1981-1985 came from Bolivia and Guyana, and most went to USA; in 1986-1990 the figure fell slightly to 1706, with Guyana the chief source, but in 1993 the country introduced an indefinite prohibition on further exports.

Bibliography. Abramson (1993b), Anon. (1993), Canevari *et al.* (1991), Chebez (1987b), Contreras *et al.* (1990), Deckert (1991), Deckert & Deckert (1982), Delorme (1979), Desenne (1994), Desenne & Strahl (1991, 1994), Haverschmidt & Mees (1994), Hayes (1995), Hilty (1985), Hilty & Brown (1986), Hohmann (1984), Inskipp *et al.* (1988), López (1992), Low (1972, 1997g), McLoughlin & Burton (1970), Meyer de Schauensee & Phelps (1978), Munn (1988), Nazimuddeen (1991), Nores & Yzurieta (1994), Nycander *et al.* (1995), O'Neill (1981), Olmos (1993), de la Peña (1988), Pinto (1946), Pulido (1991), Ridgely (1981), Ridgely & Gwynne (1989), Rigge (1963), Robbins *et al.* (1985), Short (1975), Sick (1985, 1993), Snyder (1966), Soos (1996), Stotz *et al.* (1996), Terborgh *et al.* (1990), Thiollay (1988), Tostain *et al.* (1992), Wetmore (1968), Whitney (1996), Willis & Oniki (1981).

195. Red-fronted Macaw

Ara rubrogenys

French: Ara de Lafresnaye German: Rotohara Spanish: Guacamayo de Cochabamba

Taxonomy. *Ara rubro-genys* Lafresnaye, 1847, Bolivia. Monotypic.

Distribution. C Bolivia.

Descriptive notes. 55-60 cm; 450-650 g. Broad red forehead running up and back to above eye; bare orbital ring and strip at base of bill pale pinkish red; rear ear-coverts, shoulder patch, underwing-coverts and thighs red; rest of body green except turquoise in flight-feathers and distal half of tail. Immature has reduced red throughout.

Habitat. Arid montane scrub, deciduous and cactus woodland in intermontane valleys and gorges at 1100-2500 m, common tree genera being *Prosopis*, *Carica*, *Acacia*, *Mimosa*, *Gourliea*, *Schinus*, *Schinopsis*, *Aspidosperma*, *Jacaranda*, *Erythrina*, *Salix*, *Alnus* and

Dodonea, with such cacti as *Cleistocactus*, *Lobivia*, *Echinopsis*, *Opuntia*, *Quiabentia* and *Cereus*.

Food and Feeding. The legumes *Schinopsis quebracho* and *Prosopis chilensis* and a cactus *Cereus* (or *Neocardenasia*) are important; so also are *Schinus*, *Aspidosperma*, *Cnidoscolus*, *Jatropha*, *Erythrina*, *Ziziphus* and the grasses *Tribulus* and *Cenchrus*; also cultivated crops of maize and groundnuts. These and other foods become available at various stages of the year, so each may have considerable value to the species.

Breeding. Oct-Mar, sometimes later, but apparently timed so that fledging coincides with period of maximum food availability, in Feb-Mar. Nest in fissure in cliff; often loosely colonial. Eggs 1-3; in captivity, incubation 26 days, nestling period 70-73 days.

Movements. No evidence of any displacements.

Status and Conservation. ENDANGERED. CITES I. A BirdLife "restricted-range" species. Although the subject of several recent studies, total population difficult to assess: figures of 1000-3000 and 3000-5000 have been put forward, yet only 555-626 were censused in the main range in 1991, so possibly less than 1000 survive. Several hundred birds were reputedly trapped annually up to 1987, although trade has not been flagged as a problem since. However, the birds' depredation of local crops results in some persecution by farmers, some of whom appear very recently to have acquired firearms for the purpose, and the steady clearance and degradation of woodland by charcoal-burners, firewood-gatherers and goats is rendering the long-term prospects for the species very doubtful.

Bibliography. Abramson (1993b), Beissinger & Snyder (1992), Boussekey *et al.* (1991a, 1991b, 1992), Brace *et al.* (1995), Christiansen & Pitter (1993a, 1993b), Clarke & Durán (1991), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), DeLoach (1982, 1983), Fjeldså & Krabbe (1990), Freud (1993c), Krabbe *et al.* (1996), Lanning (1982, 1991a), Low (1972, 1994b, 1997g), Müller-Bierl & Cordier (1991), Norez & Yzurieta (1984), Pitter & Christiansen (1995), Remsen & Traylor (1989), Remsen *et al.* (1986), Ridgely (1981), Robiller *et al.* (1988a), Romero (1974a, 1974b), Simmons (1993), Stotz *et al.* (1996), Wege & Long (1995), Whitney (1996).

196. Chestnut-fronted Macaw

Ara severa

French: Ara vert German: Rotbugara Spanish: Guacamayo Severo
Other common names: Severe Macaw

Taxonomy. *Psittacus severus* Linnaeus, 1758, Indies; error = Amazon River.

Usually treated as comprising two races, with W populations (*castaneifrons*) being marginally larger, but differences likely to be clinal. Monotypic.

Distribution. E Panama and Colombia S and E through Ecuador, E Peru and N Bolivia to C & NE Brazil, Venezuela and the Guianas.

Descriptive notes. 46-51 cm; 285-387 g (other data suggest mean of 430 g). Narrow dark chestnut frontal band, rest of crown dull turquoise; bare facial patch extending over eye white, bordered below and under chin by narrow dark brown line; rest of body green but with red shoulder, carpal area and lesser underwing-coverts, blue primary coverts and primaries, turquoise vent and reddish tail with blue tip. Immature undescribed.

Habitat. Seasonally flooded (*várzea*) forest, early successional growth along rivers, gallery woodland, palm-rich borders of slow-moving rivers and swampy areas, second growth, old

plantations and clearings with scattered large trees, temporarily or permanently wet areas with

Mauritia palm stands; occasionally in humid lowland *terra firme* forest. Generally up to 600 m, but 1500 m recorded in Ecuador, perhaps as seasonal wanderer.

Food and Feeding. Seeds of *Sclerolobium albiflorum*, *Sapium aereum*, *Cedrela odorata*, *Cupania cinerea*, pulp of *Hyeronima* and *Ficus*, pulp and seeds of *Inga laterifolia*, *Micropholus melinoneana*, *Euterpe precatória*, *Citharexylum poeppigii* and *Gulielma*, fruit of *Hura crepitans*, *Feuillea*, *Cecropia* and *Cariniana*, leaves of *Cecropia miparia* and *Sterculia excelsa*, flowers of *Quararibea cordata*, *Virola surinamensis* and *Erythrina amazonica*, bark of *Ceiba pentandra*.

Breeding. Feb in Panama; Mar-May in Colombia and Surinam; Sept-Dec or later in SC Brazil. Prefers tall dead palms, in one case *Roystonea*, often over water. Eggs 2; in captivity, incubation 28 days, nestling period not more than 9 weeks.

Movements. No evidence other than the possible vertical movement noted above.

Status and Conservation. Not globally threatened. CITES II. No evidence of any substantial decline in overall numbers; indeed may increase range with patchy forest clearance creating longer edges. Fairly common in Darién, Panama, but illegal trade persistent in region. Extinct in Cauca valley, W Colombia, but elsewhere maintaining presence, and abundant at Los Katíos National Park in NW in 1989. Extensive clearance for open farmland in W Ecuador has caused a decline, but common to abundant in E Ecuador and Peru, with a density of 1 pair/km² in Manu National Park. Recently extended its range to become breeding resident in Henri Pittier National Park, but burning of deciduous forest in N Venezuelan range causing a local decline, and some pressure from local trade. Common in parts of Surinam, but relatively rare in French Guiana, and evidently at edge of range in Guyana, where rare. International trade not considered a problem: Bolivia exported 6417 in years 1981-1984 but then banned all psittacine commerce.

Bibliography. Desenne (1994), Desenne & Strahl (1991, 1994), Fernández-Badillo *et al.* (1994), Friedmann (1948b), Haverschmidt & Mees (1994), Hilty & Brown (1986), Inskipp *et al.* (1988), Low (1972, 1997g), McLoughlin & Burton (1970), Meyer de Schauensee & Phelps (1978), Mullick (1969), Munn (1988), O'Neill (1974, 1981), Pulido (1991), Ratcliffe (1984), Ridgely (1981), Ridgely & Gwynne (1989), Scharringa (1975), Sick (1985, 1993), Snyder (1966), Stotz *et al.* (1996), Terborgh *et al.* (1990), Tostain *et al.* (1992), Vit (1988), Wetmore (1968), Whitney (1996).

Genus *ORTHOPSITTACA* Ridgway, 1912

197. Red-bellied Macaw

Orthopsittaca manilata

French: Ara macavouanne German: Rotbauchara Spanish: Guacamayo Ventrirrojo

Taxonomy. *Psittacus manilatus* Boddaert, 1783, Cayenne.

Normally included in genus *Ara* (see page 284). Monotypic.

Distribution. SE Colombia S to E Ecuador, E Peru and N Bolivia, and E through Venezuela, Trinidad and the Guianas to NC & NE Brazil.

Descriptive notes. 50-51 cm; 292-390 g. Bare facial patch from base of bill above and behind eye pale yellowish; forehead grey-blue shading through dull blue to green on nape and rest of plumage, but with brownish red patch on belly, bluish green undertail-coverts, primary coverts and primaries above blue, undersides of flight-feathers and tail olive-yellow. Immature undescribed.

Habitat. *Mauritia* palm stands in seasonally or permanently inundated savannas and partly forested lands and along creeks, gallery forest and tall mangroves, penetrating parklands and plantations near settlements. Up to 500 m.

Food and Feeding. Almost exclusively the fruits of *Mauritia* palms, but *Euterpe* and *Roystonea oleracea* also recorded.

Breeding. Feb-Jun in Guyana; Feb and Sept, Trinidad; bird visiting hole in stub in Sept, Brazil. Nest in hole in dead palm, of which base commonly in water, possibly giving protection against predation; on Trinidad often in just-vacated hole of *Amazona amazonica*. Eggs 2 (in captivity 4); also in captivity, incubation lasts 25 days, and nestling period 73-78 days.

Movements. At a site in Bolivia, Sept-Nov, the species was common but in another year it could not be found. Nov-Jan, suggesting either annual fluctuations in numbers or some migratory pattern, presumably in response to annual or seasonal differences in *Mauritia* phenology across its wide range.

Status and Conservation. Not globally threatened. CITES II. Generally common to abundant throughout range with the exception of Colombia and Guyana, where uncommon: *Mauritia* palm stands tend to be left by human colonists, so this bird is little affected by forest clearance within range, and it is relatively little sought-after for trade. However, in Venezuela there is some commercial exploitation and habitat loss, in French Guiana industrial use of palms is considered a potential threat to the species, while in Guyana around 1980 a proposed dam was expected to reduce its habitat substantially, combined with an annual average of 383 birds exported 1981-1985, was a source of concern for its future in the country.

Bibliography. Desenne & Strahl (1991, 1994), French (1991), Friedmann & Smith (1955), Haverschmidt & Mees (1994), Herklots (1961), Hilty & Brown (1986), Inskipp *et al.* (1988), Low (1972, 1987a, 1997g), McLoughlin & Burton (1970), Meyer de Schauensee & Phelps (1978), Niles (1981), O'Neill (1981), Parker & Remsen (1987), Pearson (1975a), Pinto (1964), Remsen & Ridgely (1980), Ridgely (1981), Roth (1984a), Sick (1985, 1993), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Whitney (1996), Willis & Oniki (1993).

Genus *PROPYRRHURA* Miranda-Ribeiro, 1920

198. Blue-headed Macaw

Propyrrhura couloni

French: Ara de Coulon German: Blaukopfara Spanish: Guacamayo Cabeciazul

Taxonomy. *Ara couloni* P. L. Slater, 1876, eastern Peru.

Normally placed in genus *Ara* (see page 284). Forms superspecies with *P. maracana* and *P. auricollis*; sometimes considered conspecific with former. Monotypic.

Distribution. E Peru and extreme W Brazil S to N Bolivia.

Descriptive notes. 41 cm; 207-294 g. Head blue; small bare facial patch from bill around eye greyish; body green; edge of wing, primary coverts and flight-feathers blue; tail above dull reddish shading at tip to blue; wings and tail below dusky yellow. Immature undescribed.

Habitat. Edge of humid lowland evergreen forest, along rivers and by clearings and other breaks in continuous canopy, locally even on the outskirts of towns; lowlands to 1550 m.

Food and Feeding. No information.

Breeding. Young birds observed in company of adults in Apr.

Movements. Occurrence in lowland SE Peru erratic.

Status and Conservation. Not globally threatened. CITES II. One of the least known of South American parrots. Although it is usually reported as uncommon to rare, it can be locally fairly common, especially around settlements; and owing to its habitat preferences, patchwork clearance of forest within its range may even cause an increase in overall population. Recent observations suggest it is commoner in foothills than the lowlands in Manu National Park; 4-6 birds per day seen in the Salvación and Atalaya area of the park, but reproductive output very low, with only one of ten pairs seen immediately after the breeding season judged to have bred successfully (accompanied by one young) in 1994. Virtually unknown in international trade.

Bibliography. Allen (1995), Low (1972, 1997g), Machado de Barros (1995), O'Neill (1981), Parker & Remsen (1987), Parker, Castillo *et al.* (1991), Parker, Parker & Plenge (1982), Pinto (1964), Pulido (1991), Ridgely (1981), Sick (1985, 1993), Stotz *et al.* (1996), Terborgh *et al.* (1984), Weske (1972), Wheatley (1994), Whitney (1996).

199. Blue-winged Macaw

Propyrrhura maracana

French: Ara d'Illiger

German: Maracana

Spanish: Guacamayo Maracaná

Other common names: Illiger's Macaw

Taxonomy. *Macrocerus maracana* Vieillot, 1816, Paraguay.

Normally placed in genus *Ara* (see page 284). Forms superspecies with *P. coultoni* and *P. auricollis*; sometimes considered conspecific with former. Monotypic.

Distribution. NE, C & SE Brazil, Paraguay and NE Argentina.

Descriptive notes. 36-43 cm; 246-266 g. Very similar to *Orthopsittaca manilata* but iris yellow not dark, not contrasting with face, forehead and patch on back red, tail above blue, reddish at base. Immature shows less red.

Habitat. Borders of tropical lowland evergreen forest, palm groves and gallery woodland penetrating *caatinga* vegetation.

Food and Feeding. No information save for a record of seeds of introduced *Melia azedarach*.

Breeding. Evidence for Dec in N Brazil; breeding condition female in Feb. Argentina. In captivity: 3 eggs; incubation lasting 26-27 days; nestling period 70 days.

Movements. Apparently sedentary, but may wander to transitional woodland.

Status and Conservation. VULNERABLE. CITES I. Although the area from which this species has been recorded is vast, in the past few decades at least it has been inexplicably difficult to find. It is probably now extinct in Misiones, Argentina, where in the 1950's it appears to have been relatively numerous. In Paraguay it is still present in Orient. In Brazil it was once common in Rio Grande do Sul but is now extinct there, and indeed only survives in the SE of the country at a handful of sites such as Fazenda Paraíso (São Paulo) and Rio Doce State Park (Minas Gerais); puzzlingly, having once been thought extinct in Rio de Janeiro it has apparently recolonized one area so well that this is perhaps its stronghold in the region. Otherwise it seems only to be at all common in the Serra Negra (Pernambuco) and the Serra do Cachimbo (Pará).

Bibliography. Belton (1984), Brooks *et al.* (1993), Canevari *et al.* (1991), Collar (1996), Collar *et al.* (1994), Eckelberry (1965), Hayes (1995), López (1992), Low (1972, 1997g), Lowen *et al.* (1996), Navas & Bó (1988), Nores & Yzurieta (1994), Olmos (1993), de la Peña (1988), Pinto (1964), Ridgely (1981), do Rosário (1996), Sick (1985, 1993), Stotz *et al.* (1996), Waugh (1997a, 1997b, 1997c, 1997d), Whitney (1996), Willis (1979), Willis & Oniki (1981).

200. Yellow-collared Macaw

Propyrrhura auricollis

French: Ara à collier jaune

German: Halsbandara

Spanish: Guacamayo Acolarado

Other common names: Golden-collared Macaw

Taxonomy. *Ara auricollis* Cassin, 1853, Bolivia. Normally placed in genus *Ara* (see page 284). Forms superspecies with *P. maracana* and *P. coultoni*. Monotypic.

Distribution. NE Bolivia and N Paraguay to EC & SW Brazil and N Argentina.

Descriptive notes. 37-45 cm; 240-250 g. Bare facial patch from base of bill above and behind eye white; forehead and area bordering lower facial patch blackish green shading to green on nape, sides of neck and rest of plumage, but with narrow yellow collar reaching to sides of breast, primary coverts and primaries above blue, undersides of flight-feathers and tail olive-yellow, tail above reddish basally shading to blue distally. Immature undescribed.

Habitat. Open *cerrado*, gallery woodland in Pantanal and deciduous Chaco woodland, also humid upper tropical forest in foothills in S of range, adapting to areas partly cleared for agriculture and ranchland; to 600 m, although as high as 1700-2000 m reported.

Food and Feeding. Fruit and seeds reported, but no specific information.

Breeding. Dec in Argentina. Nest in hole in tree, in one case 20 m from ground. Eggs 3-4; in captivity, incubation lasts around 23 days, nestling period around 7 weeks.

Movements. Near the Itenez R, Bolivia, birds were noted as common but they left the area before the end of the dry season and were thought to have moved S. Notable flocking behaviour in this species outside breeding season supports idea of at least local movements.

Status and Conservation. Not globally threatened. CITES II. Common and ecologically adaptable. Some concern over trade levels from Bolivia in late 1970's, which escalated to an annual average of 3204 in the years 1980-1983, but which was effectively curtailed with a total trade ban in 1984; rare, presumably being at edge of range, in Paraguay; although populations reported as critically low in Argentina in late 1980's, this now disproven with the species fairly common in N Salta and Jujuy, and has even colonized Calilegua National Park.

Bibliography. Canevari *et al.* (1991), Fuqua (1981), Goodfellow (1933), Hayes (1995), Hoy (1968), Inskipp *et al.* (1988), López (1992), Low (1972, 1997g), Nores & Yzurieta (1994), de la Peña (1988), Pinto (1964), Ridgely (1981), Short (1975), Sick (1985, 1993), Stone & Roberts (1935), Stotz *et al.* (1996), Whitney (1996).

Genus *DIOPSITTACA* Ridgway, 1912

201. Red-shouldered Macaw

Diopsittaca nobilis

French: Ara noble

German: Zwergara

Spanish: Guacamayo Noble

Taxonomy. *Psittacus nobilis* Linnaeus, 1758, South America = Surinam.

Commonly placed in genus *Ara* (see page 284). Three subspecies recognized.

Subspecies and Distribution.

D. n. nobilis (Linnaeus, 1758) - E Venezuela, the Guianas and N Brazil N of Amazon.

D. n. cumananensis (Lichtenstein, 1823) - N Brazil S of lower Amazon to NE Brazil.

D. n. longipennis Neumann, 1931 - SE Peru and NE Bolivia to C & SE Brazil.

Descriptive notes. 30 cm; 129-169 g. Bare facial mask from dark bill around eye white; forehead to mid-crown blue shading to green of rest of body; bend of wing, carpal edge and lesser underwing-coverts red; undersides of wings and tail dull olive-yellow. Immature lacks blue on crown and has reduced red in wing. Race *cumanensis* larger with bicoloured bill and paler forehead; *longipennis* larger still.

Habitat. Natural savannas (including *cerrado*) and marshy areas with *Mauritia* or *Orbignya* palm stands, gallery woodland, second growth, sparse *caatinga* woodland and cultivated areas adjacent to tall forest.

Food and Feeding. Seeds found in stomachs, but berries of *Cordia*, flowers of *Erythrina* and fruits of *Euterpe* reported. Flocks reported to raid crops and rice fields.

Breeding. Feb-Jun in Guyana. Nest in hole often in living palm, also in arboreal termitarium. In captivity: 4 eggs; incubation lasting 24 days; nestling period 60 days.

Movements. Possibly some wandering occurs in Surinam, where flocks occasionally noted in Sept-Oct in city areas.

Status and Conservation. Not globally threatened. CITES II. Local but fairly common across range, and not under pressure from either habitat loss or trade. Still secure in Venezuela, and likely to be so also in Guyana. Common in sandy savannas in Surinam; restricted to coastal plain in French Guiana. Locally very common in C and NE Brazil.

Bibliography. Davis (1993), Desenne & Strahl (1991, 1994), Graham *et al.* (1980), Harrison & Holyoak (1970), Haverschmidt & Mees (1994), Inskipp *et al.* (1988), Low (1972, 1997g), McLoughlin & Burton (1970), Meyer de Schauensee & Phelps (1978), O'Neill (1981), Pacheco (1994), Pinto (1964), Remsen & Ridgely (1980), Ridgely (1981), Schubart *et al.* (1965), Sick (1985, 1993), Silva (1983, 1996), Snyder (1966), Stager (1961), Stotz *et al.* (1996), Tostain *et al.* (1992), Vane (1950), Whitney (1996), Young (1929).

Genus *RHYNCHOPSITTA* Bonaparte, 1854

202. Thick-billed Parrot

Rhynchopsitta pachyrhyncha

French: Conure à gros bec

German: Kiefernstitich

Spanish: Cotorra Serrana Occidental

Other common names: Macawlet

Taxonomy. *Macrocerus pachyrhynchus* Swainson, 1827, tableland of Mexico.

Very close to *R. terrisi* but the two are probably best considered to form a superspecies. Monotypic. **Distribution.** Sierra Madre Occidental, Mexico, formerly wandering into southernmost USA, where perhaps was present for years at a time.

Descriptive notes. 38-43 cm. Green throughout but with red forehead extending as broad line over and behind eye, bare orbital ring dull yellow, red shoulders and lower thighs, and greater underwing-coverts yellow. Immature has less red.

Habitat. Temperate conifer forests including mature pine-oak, pine and fir forests, usually at 2000-3000 m. Recorded once roosting in tropical lowland deciduous forest although flying each day to feed in highland pines.

Food and Feeding. Principally seeds of various pines, most frequently *Pinus arizonica* and *P. ayacahuite*, but also *P. teocote*; irrupting birds, Arizona, fed on *P. leiophylla* seeds before switching to acorns, and elsewhere *Prunus* fruits and legume seeds have been used as supplements.

Breeding. Timed to coincide with peak pine-seed production, so slightly variable between years; eggs recorded May-Aug, and a newly fledged bird in mid-Jun. Nest in hole in tree, usually a pine, more rarely aspen (*Populus tremuloides*) or Douglas fir (*Pseudotsuga taxifolia*). Eggs 1-4, possibly variable with pine crop; incubation in captivity lasts 24-28 days.

Movements. Nomadic in response to pine crop success, thus behaving irruptively in the manner of crossbills (*Loxia*), and for the same reason. Major invasions of southernmost USA formerly occurred, and as with *Loxia* smaller numbers may have stayed to breed or have all-

ways been present. This pattern may apply in many parts of the Sierra Madre Occidental itself, with perhaps only a few core areas permanently holding the species.

Status and Conservation. **ENDANGERED.** CITES I. A BirdLife "restricted-range" species. The destruction of the pine forests of the Sierra Madre has proceeded throughout this century, and for any species dependent on food that is patchy in both space and time, the interposition of even more space between productive areas is an energetic catastrophe leading to spatio-temporal bottlenecks in food supply; it also removes nest-sites. Forest destruction is continuing with the settlement of even remote areas by cattle-ranchers and drug-growers, and with logging operations still active. This parrot is now uncommon throughout its range, and owing to its nomadic behaviour it cannot easily be protected by one or a few reserves; ironically, however, not a single reserve for the conservation of the fauna and flora of the once-extensive pine forests of the Sierra Madre Occidental exists. "Reintroduction" efforts into the USA have been carried out using confiscated cage-birds, but although there was some breeding activity the birds have largely dispersed away from the release site and disappeared.

Bibliography. Arndt (1986), Beissinger & Snyder (1992), Bent (1940), Blake & Hanson (1942), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Fleming & Baker (1963), Hanson (1987), Hawley & Brue (1995), Healy & Thormahlen (1988), Howell & Webb (1995a), Hubbard & Crossin (1974), Jeggo (1974), Johnson & Snyder (1987), Johnson *et al.* (1989), King (1978/79), Koschmann & Price (1987), Lamberton (1993), Lanning & Shiflett (1979, 1981, 1983), Leopold (1937), Low (1972), Marshall (1957), Martin (1989), Monson (1965), Ridgely (1981), Schnell *et al.* (1974), Smith (1973), Snyder & Johnson (1988, 1989), Snyder & Wallace (1987), Snyder, Koenig *et al.* (1994), Snyder, Snyder & Johnson (1989), Snyder, Toone *et al.* (1996), Stager (1954), Stotz *et al.* (1996), Taylor (1991), Vorhies (1934), Watson (1993), Wege & Long (1995), Wetmore (1935), Whitney (1996), Witt (1978), Woodard (1980).

203. Maroon-fronted Parrot

Rhynchopsitta terrisi

French: Conure à front brun **German:** Maronenstirnsittich **Spanish:** Cotorra Serrana Oriental
Other common names: Maroon-fronted Macawlet

Taxonomy. *Rhynchopsitta terrisi* R. T. Moore, 1947, near Galeana, Sierra Potosí, Nuevo León, Mexico. Forms a superspecies with *R. pachyrhyncha*, with which has often been considered conspecific. Monotypic.

Distribution. Sierra Madre Oriental, Mexico.

Descriptive notes. 40-45 cm; 392-468 g. Very like *R. pachyrhyncha* but slightly darker green with darker shoulder patch, red of head dark maroon, greater underwing-coverts olive grey. Immature has less red.

Habitat. Mixed conifer forest generally at 2000-3500 m.

Food and Feeding. Principally seeds of pines including *Pinus arizonica*, *P. gregii*, *P. teocote*, *P. montezumae* and *P. cembroides*, birds exploiting the different species in relation to their annual availability; also seeds of a fir *Abies*, acorns *Quercus* and nectar and seeds of *Agave macraculmis*.

Breeding. As in *R. pachyrhyncha*, nesting coincides with pine crop ripening, and variation in timing no less dramatic, with breeding condition males being collected in May and Oct. Nest in hole in limestone cliff, birds often breeding colonially. Eggs unrecorded, but 1-3 fledged young seen.

Movements. Although some birds may remain throughout year at given sites, there appears to be a fairly regular movement of many birds to the S of the known range for the post-breeding dry season, roughly Oct-Apr.

Status and Conservation. **VULNERABLE.** CITES I. A BirdLife "restricted-range" species. The population is not known to exceed 2000 birds, and the available habitat within its range covers only 7000 km². However, although there has been much habitat loss over time, the species's cliff-nesting habit gives it an advantage over *R. pachyrhyncha*, and there have at least been two reserves established within its range, namely Cumbres de Monterrey National Park, where 1480 birds were counted in Oct 1994, and El Taray Sanctuary near Monterrey, established in 1995 and containing an estimated 100 pairs.

Bibliography. Anon. (1996c), Arndt (1986), Beissinger & Snyder (1992), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Ely (1962), Hardy (1967), Hardy & Dickerman (1955), Howell & Webb (1995a), King (1978/79), Lanning & Lawson (1977), Lawson & Lanning (1981), Low (1972), Ridgely (1976, 1981), Robins & Heed (1951), Sada (1987), Snyder & Enkerlin (1996), Snyder *et al.* (1996), Stotz *et al.* (1996), Urban (1959), Valenzuela *et al.* (1981), Wege & Long (1995), Whitney (1996).

Genus *OGNORHYNCHUS* Bonaparte, 1857

204. Yellow-eared Parrot

Ognorhynchus icterotis

French: Conure à joues d'or **German:** Gelbohrsittich **Spanish:** Aratinga Orejigualda
Other common names: Yellow-eared Conure/Parakeet

Taxonomy. *Conurus icterotis* Massena and Souancé, 1854, Ocaña, Colombia. Monotypic.

Distribution. Andes of Colombia and N Ecuador.

Descriptive notes. 42 cm; 285 g. Bill black, forehead and face yellow, extending back to ear-coverts; bare orbital ring grey; mid-crown and area above post-ocular line to nape green, extending round sides of neck to chin, and continuing throughout upperparts and wings, except shoulder yellow; breast and belly yellow shading to greenish on thighs and vent; tail green above, dusky reddish below. Immature undescribed.

Habitat. Humid forest and partially cleared terrain, especially where wax palms (*Ceroxylon*) occur in extensive stands; chiefly at 2000-3000 m, with overall range of 1200-3400 m.

Food and Feeding. Wax palm nuts probably of various species, with *C. quindiuense* and *C. alpinum* recorded, also fruit of *Saurauia tomentosa* and *Sapium*.

Breeding. Mar-May in Colombia; Jul-Oct in Ecuador. Breeds colonially in mature stands of wax palms. Nest in hole high (over 25 m) in *C. quindiuense* in Colombia, *C. ventricosum* in Ecuador, found at 2000-2600 m. Eggs 4. No further information.

Movements. Flocks probably wander nomadically or seasonally in search of food, and if this so then the loss of much feeding habitat will have rendered the species highly exposed to temporal failures in food supply.

Status and Conservation. **CRITICALLY ENDANGERED.** CITES I. Having once been common to abundant locally, this species has suffered a catastrophic collapse of numbers in response to the near-total clearance of Colombia's national tree, the wax palm *C. quindiuense*. Regeneration of these plants is inhibited by cattle-grazing and kikuyu grass, and several species are themselves threatened. The parrot itself has become so rare that it can no longer be found in Colombia, or at least the few birds encountered do not remain on site for long. Colonial nesting behaviour renders birds more vulnerable to trapping, and although little trade ever recorded this bird would now command enormous prices in illicit markets. A tiny population recently discovered in Ecuador is in great need of major conservation effort, but nomadic nature of species may render efforts of little long-term effect.

Bibliography. Arndt (1986), Beissinger & Snyder (1992), Butler (1979), Chapman (1917, 1926), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Fjeldså & Krabbe (1990), Hilty & Brown (1986), King (1978/79), Krabbe & Sornoza (1996), Lehmann (1957), Lönnberg & Rendahl (1922), Low (1972), Meyer de Schauensee (1949), Orejuela (1985), Ridgely (1981), Rodríguez & Hernández (1988), Smith (1977a), Stotz *et al.* (1996), Waugh (1996b), Wege & Long (1995), Whitney (1996).

Genus *GUAROUBA* Lesson, 1831

205. Golden Parakeet

Guarouba guarouba

French: Conure dorée **German:** Goldsittich **Spanish:** Aratinga Guaruba
Other common names: Golden Conure

Taxonomy. *Psittacus Guarouba* J. F. Gmelin, 1788, north-eastern Brazil.

Genus name often spelt *Guaruba*, but original spelling is *Guarouba*. Often placed in genus *Aratinga*. Monotypic.

Distribution. N Brazil in N Maranhão and Pará; recent single records from Rondônia and Mato Grosso.

Descriptive notes. 34-36 cm. Bright yellow throughout, but flight-feathers dark green. Immature has green markings on head, breast and tail.

Habitat. *Terra firme* rain forest, mainly in flooded areas, wandering into seasonally hilly *várzea* forest at times and occupying more open areas, including riverine grasslands with scattered trees, to breed.

Food and Feeding. Fruits or pseudofruits of *Euterpe*, *Anacardium*, *Protium*, *Tetragastris*, *Visnia*, *Inga*, *Byrsonima*, *Carapa*, *Cecropia* and *Oenocarpus*, buds and flowers of *Symphonia*. Attacks maize crops and takes mangoes.

Breeding. Nov-Feb, sometimes earlier or later. Nest high in hole in tree, usually isolated but within short distance of intact forest. Eggs apparently 2-3 per pair, but birds often breed communally with up to 9 young reported in nests with multiple attendants; possibly one female lays, adjusting clutch size to number of helpers available; in a captive group of three males and three females, all six helped rear 14 young. Incubation in captivity lasts around 30 days.

Movements. Apparently nomadic, with birds seeming to wander widely and not predictable at one locality at any one season. Post-breeding dispersal seems, however, to take birds regularly into *várzea*, Feb-Apr.

Status and Conservation. **ENDANGERED.** CITES I. Massive habitat destruction now accelerating within main range of species, where major roads now bisect it both N-S and E-W, compounded by unknown but doubtless intense levels of smuggling of what is one of the most prized birds in aviculture. Persecution as a crop pest, and hunting for both food and sport, are further causes for alarm. Recorded in Amazonia National Park (Pará), Jamari National Forest (Rondônia) and Gurupi Forest Reserve (Maranhão).

Bibliography. Beissinger & Snyder (1992), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Descourtiz (1983), Forrester (1993), Hayward (1993), Hellmayr (1929), Hill (1939), King (1978/79), Lieberman (1990), Lo (1995), Low (1972, 1994b, 1995d), Oren & Novaes (1986), Oren & Willis (1981), Pinto (1946, 1964), Ridgely (1981), Schubart *et al.* (1965), Sick (1985, 1990, 1993), Stotz *et al.* (1996), Turner (1940), Walters (1974), Wege & Long (1995), Wenner (1978), Whitney (1996), Yamashita & França (1991).

Genus *ARATINGA* Spix, 1824

206. Blue-crowned Parakeet

Aratinga acuticaudata

French: Conure à tête bleue **German:** Spitzschwanzsittich **Spanish:** Aratinga Cabeciazul
Other common names: Blue-crowned Conure

Taxonomy. *Psittacus acuticaudatus* Vieillot, 1818, Paraguay. Five subspecies recognized.

Subspecies and Distribution.

A. a. koenigi Arndt, 1995 - NE Colombia and N Venezuela.
A. a. neoxena (Cory, 1909) - 1 Margarita (Venezuela).
A. a. haemorrhous Spix, 1824 - interior NE Brazil.
A. a. neumanni Blake & Traylor, 1947 - upland E Bolivia.
A. a. acuticaudata (Vieillot, 1818) - E Bolivia, Paraguay and SW & S Brazil to W Uruguay (extinct?) and N Argentina.

Descriptive notes. 33-38 cm; 170-176 g. Head dull blue, bare orbital ring white; body and wings green, paler below, sometimes with blue tinge on breast; tail old gold below with reddish inner webs basally, green above with outer feathers brownish red and tipped dark yellow-green. Immature has reduced blue on head. Race *neumanni* has forehead to nape blue, rest of head green, underparts washed blue; *haemorrhous* has only forecrown blue, no bluish wash below, and lower mandible horn-coloured; *koenigi* like *haemorrhous* but much smaller, with less red to inner webs of undersides of tail; *neoxena* same size as *koenigi* but

breast and abdomen bluish green.

Habitat. Arid thornbush, cactus scrub, dry woodland, gallery woodland, *cerrado*, open savanna with *Mauritia* palm stands, Chaco. To 400 m, Colombia, 600 m Venezuela; race *neumanni* occurs at 1500-2650 m in thorny leguminaceous wood with columnar cacti.

Food and Feeding. Berries (e.g. *Condalia lineata*), seeds, nuts, fruits of large cacti. Takes ripe mangoes and attacks corn and sorghum crops, although also said to take seeds of noxious weeds.

Breeding. Apparently Mar-Jul, Venezuela; May-Aug., 1 Margarita; Dec in Argentina. Nest in hole high in tree; on Margarita, *neoxena* uses only the mangrove *Avicennia germinans*. Eggs 2 (Argentina), 3-5 (*neoxena*); in captivity, incubation lasting 23 days, nestling period 50 days.

Movements. In Colombia described as common in gallery woodland, Mar-Jul, but absent rest of year; as these dates coincide with reported breeding season in adjacent Venezuela, the Colombian record may reflect breeding presence and habitat. Clearly some movements occur. Race *neumanni* in Andes nomadic, and other populations likely to show complex movements in response to seasonal changes in food availability.

Status and Conservation. Not globally threatened. CITES II. Common in many parts of range, and officially declared a pest species in Argentina, where more abundant than *Myiopsitta monachus* in Chaco. This country responsible for majority of birds in trade throughout 1980's, when over 15,000 per year were logged on CITES import records; the cumulative effect of this considered probably serious. Generally uncommon in Paraguay. Last recorded in Uruguay over 50 years ago. Race *neoxena* highly threatened by taking of young for pets (although nests situated in La Restinga National Park) and by rat predation of nests, with only 100-200 individuals remaining.

Bibliography. Anon. (1993), Arndt (1980b), Blake & Traylor (1947), Canevari *et al.* (1991), Collar (1997), Contreras *et al.* (1990), Desenne & Strahl (1991, 1994), Fjeldså & Krabbe (1990), Hayes (1995), Hilty & Brown (1986), Inskipp *et al.* (1988), López (1992), Low (1972), Meyer de Schauensee & Phelps (1978), Norez & Yzurieta (1994), de la Peña (1988), Pereira (1994), Ridgely (1981), Rodríguez & Rojas-Suárez (1994), Rojas-Suárez (1994a), Short (1975), Sick (1985, 1993), Stotz *et al.* (1996), Wetmore (1926, 1939), Whitney (1996).

207. Green Parakeet

Aratinga holochlora

French: Conure verte **German:** Grünsittich **Spanish:** Aratinga Verde
Other common names: Green Conure; Pacific Parakeet (*strenua*)

Taxonomy. *Conurus holochlorus* P. L. Sclater, 1859, Jalapa, Vera Cruz.

Often considered conspecific with *A. brevipes* and *A. rubritorquis*. Race *strenua* often regarded as a separate species (see page 285). Three subspecies currently recognized.

Subspecies and Distribution.

A. h. brewsteri Nelson, 1928 - NW Mexico.
A. h. holochlora (P. L. Sclater, 1859) - NE to S Mexico.
A. h. strenua (Ridgway, 1915) - S Mexico to N Nicaragua.

Descriptive notes. 32 cm; 232 g. Green, more yellowish below; bare orbital ring pale pinkish grey; some birds with a few red flecks on head; underwing-coverts yellowish; tail and flight-feathers olive yellow below. Immature similar to adult. Race *brewsteri* slightly glaucous on head, and generally darker; *strenua* larger and more olivaceous than nominate, with generally larger bill.

Habitat. Deciduous, semi-deciduous, evergreen and gallery woodland, Pacific swamp forest, arid tropical scrub, clearings, edge and upland pine-oak formations; lowlands to 1500 m, but at 1500-2000 m in NW of range and *strenua* reaching 2600 m in Guatemala.

Food and Feeding. Few details; *Mimosa* seeds, *Myrica mexicana* fruits, and maize recorded, and evidently sometimes a crop pest.

Breeding. Season seemingly extended (perhaps in certain years only), with a breeding condition male collected in Aug in Guatemala, and a cliff-nesting colony with young in Jan in Mexico; otherwise generally reported Feb-Apr. Nest in hole in tree, termitarium, or, colonially, in rock crevices in cliffs. In captivity: 4 eggs; incubation lasting 23 days; nestling period 50 days.

Movements. At least local movements occur in response to food supply.

Status and Conservation. Not globally threatened. CITES II. All subspecies remain or have been found to be frequent to common in recent

years. Apparently little affected by habitat destruction; relatively low levels of international trade, 93% of all recorded birds (3000) reported to CITES in 1985-1990 coming from Honduras.

Bibliography. Anon. (1983, 1993), Bangs & Peters (1928), Binford (1989), Clinton-Eitnienar (1984a), Dickey & van Rossem (1938), Edwards & Lea (1955), Gehlbach *et al.* (1976), Griscom (1932), Harrison & Holyoak (1970), Howell & Webb (1995a), Inskipp *et al.* (1988), Land (1970), Lever (1987), Low (1972), Lowery & Dalquest (1951), Monroe (1968), Ridgely (1981), Stotz *et al.* (1996), Sutton & Pettingill (1942), Thurber *et al.* (1987), Wermundsen (1997), Whitney (1996).

208. Socorro Parakeet

Aratinga brevipes

French: Conure de Socorro **German:** Socorrosittich **Spanish:** Aratinga de Socorro
Other common names: Socorro Conure

Taxonomy. *Conurus holochlorus* var. *brevipes* Lawrence, 1871, Socorro Island.

Very closely related to and usually considered conspecific with *A. holochlora*, but vocal, structural and plumage differences combine to suggest specific status appropriate. Monotypic.

Distribution. Socorro I, off SW Mexico.

Descriptive notes. 31-33 cm. Like *A. holochlora*, but darker green below, orbital skin tinged purplish brown.

Habitat. Forest of *Bumelia socorrensis*, *Ilex socorrensis* and *Guettarda insularis*, mostly above 500 m.

Food and Feeding. Seeds and pulp of *Bumelia* (51% of feeding records), *Guettarda* (19%), *Ilex* (17%) and *Psidium socorrensis* (13%).

Breeding. Oct-Jan. Nest in hole in *Bumelia socorrensis* tree, 2-3-3-8 m above ground, hole orientation in 7 cases was towards S or SW.

Movements. Sedentary.

Status and Conservation. VULNERABLE.

CITES II. A BirdLife "restricted-range" species. Population in 1990-1991 estimated at 400-500 birds in the 35 km² of suitable habitat on the island. Persistent habitat degradation by sheep may affect the species in the near future.

Bibliography. Beissinger & Snyder (1992), Brattstrom & Howell (1956), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Howell & Webb (1995a), Low (1972), Rodríguez-Estrella, Mata & Rivera (1992), Rodríguez-Estrella, Rivera & Anguiano (1995), Stotz *et al.* (1996), Wege & Long (1995), Whitney (1996).

209. Red-throated Parakeet

Aratinga rubritorquis

French: Conure à gorge rouge **German:** Rotkehlstittich **Spanish:** Aratinga Gorgirroja
Other common names: Red-breasted Parakeet/Conure

Taxonomy. *Conurus rubritorquis* P. L. Sclater, 1887, South America or West Indies; error = Central America.

Usually considered conspecific with *A. holochlora* but distinct in morphology and to some extent habitat, and apparently also in behaviour and voice. Monotypic.

Distribution. Highlands of E Guatemala and El Salvador (apparently one record only) S through Honduras to N Nicaragua.

Descriptive notes. 26-29 cm. Similar to *A. holochlora*, but decidedly smaller, orbital skin tinged brownish grey, with variable but usually extensive reddish orange chin, throat and foreneck. Immature lacks red on throat.

Habitat. Semi-arid to semi-humid highland pine and pine-oak woodland and adjacent semi-deciduous forest and cloud forest, 600-1800 m or higher.

Food and Feeding. No specific information other than that it prefers waxberries *Myrica mexicana*.

Breeding. No specific information other than that nesting occurs colonially in rock wall.

Movements. Nomadic in non-breeding season (Nov-Apr), ranging down to near sea-level.

Status and Conservation. Not globally threatened. CITES II (where covered by *A. holochlora*). Frequent to common apparently throughout range. Apparently little affected by habitat destruction; relatively low levels of international trade.

Sun Parakeet (*Aratinga solstitialis*); 218. Jandaya Parakeet (*Aratinga jandaya*); 219. Golden-capped Parakeet (*Aratinga auricapilla*); 220. Dusky-headed Parakeet (*Aratinga weddellii*); 221. Olive-throated Parakeet (*Aratinga nana*).

Bibliography. Arndt (1978), Dearborn (1907), Dickey & van Rossem (1938), Howell & Webb (1995a), Land (1970), Lawton (1992), Low (1972), Monroe (1968), Ridgely (1981), Steinbacher (1956), Stotz *et al.* (1996), Sweeney (1997c), Thurber *et al.* (1987), Whitney (1996).

210. Scarlet-fronted Parakeet

Aratinga wagleri

French: Conure de Wagler **German:** Columbiasittich **Spanish:** Aratinga de Wagler
Other common names: Red-fronted Parakeet/Conure; Cordilleran Parakeet (*frontata*)

Taxonomy. *Conurus Wagleri* G. R. Gray, 1845, Bogotá. Possibly conspecific with *A. mitrata*. Race *frontata* sometimes considered a distinct species, incorporating race *minor*. Four subspecies normally recognized.

Subspecies and Distribution.

A. w. wagleri (G. R. Gray, 1845) - W & N Colombia to NW Venezuela.

A. w. transilis J. L. Peters, 1927 - E Colombia to N Venezuela.

A. w. frontata (Cabanis, 1846) - W Ecuador and W Peru.

A. w. minor Carriker, 1933 - C & S Peru.

Descriptive notes. 36 cm; 162-217 g. Green, yellower on underparts; forehead and crown red, with some red flecks on throat and bare orbital ring white; greater underwing-coverts, undersides of flight-feathers and tail olive yellow. Immature with reduced red on head. Race *transilis* generally darker; *frontata* has red on head extending to lores and eyes, plus carpal edge and thighs red, and strongly washed bronzy yellow; *minor* like *frontata* but smaller, darker.

Habitat. Light montane evergreen (cloud) forest edge (*Acacia*, *Prosopis* and *Ochroma*), tropical deciduous forest, secondary growth, gallery woodland, semi-humid or humid montane scrub including cactus formations, also fields and orchards, even town parks; most important requirement apparently cliff faces on which to nest and roost; 350-3000 m, occasionally in lowlands.

Food and Feeding. No detailed information. Large flocks reportedly raid croplands, notably maize, causing significant damage.

Breeding. Apr-Jun in Venezuela; Dec-Jun in N Colombia. Nest in fissure in cliff face; breeds colonially.

Movements. Numbers may fluctuate seasonally. Large numbers pass daily through Portachuelo Pass, Venezuela. Jan-Jul, but species almost entirely absent, Sept-Dec.

Status and Conservation. Not globally threatened. CITES II. In many parts of range abundant, and reportedly unaffected by loss of forests; however, evidently reduced in numbers in Colombia, where along with Peru sometimes persecuted as crop pest; reasons for decline in Colombia not clear, but presumably in this case habitat clearance. Still very common in parts of Peru, which exported 16,644 birds in 1982 but subsequently reduced international trade levels substantially, although these began rising again in the early 1990's. Heavily traded, at least internally, in Venezuela.

Bibliography. Butler (1979), Desenne & Strahl (1991, 1994), Fernández-Badillo *et al.* (1994), Fjeldså & Krabbe (1990), Hilty (1985), Hilty & Brown (1986), Inskipp *et al.* (1988), Johnson (1967), Koepeke (1970), Lehmann (1960), Lentino & Portas (1994), Low (1972), Meyer de Schauensee (1944), Meyer de Schauensee & Phelps (1978), Miller (1963), Morrison (1948), O'Neill (1981), Parker *et al.* (1982), Ridgely (1981), Stotz *et al.* (1996), Vriends (1979), Wetmore (1939), Whitney (1996).

211. Mitred Parakeet

Aratinga mitrata

French: Conure mitrée **German:** Rotmaskensittich **Spanish:** Aratinga Mitrada
Other common names: Mitred Conure; Chapman's Parakeet (*alticola*)

Taxonomy. *Conurus mitrata* Tschudi, 1844, Peru. Possibly conspecific with *A. wagleri*. Race *alticola* sometimes considered separate species. Two subspecies currently recognized.

Subspecies and Distribution.

A. m. mitrata (Tschudi, 1844) - C Peru and CE Bolivia to NW Argentina.

A. m. alticola Chapman, 1921 - C Peru in temperate zone at 3400 m.

Descriptive notes. 31-38 cm; 219-275 g. Similar to *A. wagleri frontata*, but forehead purplish and red extending variably, often in flecks, onto cheeks and ear-coverts, but bend of wing only sometimes with red. Immature has reduced red. Race *alticola* has glaucous cast with red restricted to narrow frontal band and a few facial flecks.

Habitat. Montane evergreen and deciduous woodland edge, cloud forest patches, secondary forest, semi-humid and humid montane scrub in arid montane country, 1000-3400 m.

Food and Feeding. No detailed information. Ripening berries and maize recorded.

Breeding. Dec in Argentina. Nest in hollow of tree, also in cliffs. Eggs 2-3.

Movements. Apparently wandering post-breeding flock. Jan, SE Bolivia, and seasonally numerous in intermontane valleys of E Cochabamba; noted among other immigrant parrot species in Lerma valley, NW Argentina, in pursuit of ripening berries.

Status and Conservation. Not globally threatened. CITES II. Generally common and locally abundant. Before mid-1984 virtually all birds in international trade were from Bolivia, which exported 35,100 in the years 1981-1984. In period 1985-1990 no fewer than 108,033 birds exported from Argentina, judged a serious threat that was curbed in 1993 when no quota was authorized.

Bibliography. Anon. (1993), Babarskas *et al.* (1995), Canevari *et al.* (1991), Eisenraui (1935), Fjeldså & Krabbe (1990), Hoppe (1982), Hoy (1968), Inskipp *et al.* (1988), Low (1972), Morrison (1948), Nores & Yzurieta (1994), O'Neill (1981), Orfila (1936), de la Peña (1988), Remsen *et al.* (1986), Ridgely (1981), Stotz *et al.* (1996), Wheatley (1994), Whitney (1996), Zimmer (1930).

212. Red-masked Parakeet

Aratinga erythrogenys

French: Conure à tête rouge **German:** Guayaquilsittich **Spanish:** Aratinga de Guayaquil
Other common names: Red-masked Conure

Taxonomy. *Psittacara (psittacus) Erythrogenys* Lesson, 1844, Guayaquil.

As result of different generic placement, species name formerly listed as *rubrolaryvatus*. Monotypic.

Distribution. W Ecuador and NW Peru.

Descriptive notes. 33 cm. Red forehead, crown and face, with bare orbital ring white; rest of body and wings green, slightly yellowish below, except for shoulder, edge of wing and outermost underwing-coverts red, lower thigh red, underside of wing and tail olive yellow. Immature lacks most red.

Habitat. Chiefly deciduous woodland and adjacent habitats including dry *Acacia* scrub, cultivated land and the edges of towns, but also penetrates both more humid forest and open, sparsely vegetated desert.

Food and Feeding. Likely to be highly variable with season and habitat, but little re-

corded; fruit of Anacardiaceae, Oleaceae and Boraginaceae and *Hyeronima*, flowers of *Erythrina*. **Breeding.** Jan-Mar in Ecuador; Mar-Jul in Peru. Nest in termittarium or hole 2.5-10 m up in tree such as *Ceiba trichistandra* or *Cochlospermum vitifolium*. Eggs 2-4; in captivity, incubation 23 days, nestling period six weeks.

Movements. On Santa Elena Peninsula, Ecuador, birds (probably post-breeding) usually arrive after start of rains in Apr; in Azuay, Ecuador, birds are seemingly absent in rains, Jan-Mar. Shows unpredictable variations in numbers between years, e.g. scarce to numerous on Santa Elena Peninsula, presumably in response to food availability and perhaps other factors such as breeding success in relation to wet/dry periods.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. Formerly locally common to abundant, with thousands being witnessed over Guayaquil in 1970's, but some populations have suffered steep declines and no record since 1987 has concerned more than 200 birds together. Although recorded from broad spectrum of habitats, ecological needs poorly understood and true effect of extensive habitat loss and disturbance within its range unknown. Trade impact severe, however, with this the commonest captive parrot in its range, and the tenth commonest Neotropical parrot imported into USA, 1981-1985, with 26,375 recorded. In 1993 CITES parties suspended import of the species until Peru establishes an appropriate quota level.

Bibliography. Arndt (1981), Best & Clarke (1991), Best & Kessler (1995), Best, Checker *et al.* (1996), Best, Clarke *et al.* (1993), Best, Krabbe *et al.* (1995), Bloch *et al.* (1991), Butler (1979), Collar (1996), Inskipp & Corrigan (1992), Low (1972), Marchant (1958), O'Neill (1981), Ord (1995), Parker *et al.* (1982), Ridgely (1981), Stotz *et al.* (1996), Wheatley (1994), Whitney (1996), Williams & Tobias (1994).

213. Crimson-fronted Parakeet

Aratinga finschi

French: Conure de Finsch **German:** Veraguasittich **Spanish:** Aratinga de Finsch
Other common names: Finsch's Parakeet/Conure

Taxonomy. *Conurus finschi* Salvin, 1871, Bugaba, Chiriquí, Panama.

May form a superspecies with *A. leucophthalmus*, with which has been considered conspecific, on basis that *A. l. niceforti* (known from one specimen) is intermediate between present species and *A. l. callogenis*. Monotypic.

Distribution. SE Nicaragua, Costa Rica (primarily Caribbean slope) and W Panama.

Descriptive notes. 28 cm; 150 g. Mostly green, more yellowish below; forehead red, rest of head with a few red flecks; bare orbital ring white; edge of wing and outer underwing-coverts red, often tinged orange; greater underwing-coverts yellow; undersides of flight-feathers and tail olive yellow; thigh with red spot. Immature has reduced red.

Habitat. Light woodland and forest edge, ranchlands with scattered groves, coffee plantations, second growth, agricultural districts, roosting in groves often in or near towns. Ranges up to 1650 m.

Food and Feeding. Flowers and fruits of *Erythrina* and *Inga*, fruits of *Croton*, *Zanthoxylum*, wild figs. Sometimes a pest of maize and sorghum crops.

Breeding. Reportedly Jul in Panama; in Costa Rica, dry and early wet season, i.e. Dec-May. Nest in hole in tree, often old palm stub; may excavate hole in rotten wood or epiphytic mass. Many pairs sometimes nest close together. Eggs 2-4.

Movements. Flocks appear to wander widely over much of year, with irregular or seasonal presence in some places. Numbers increase on Pacific side of Costa Rica in dry season. Probably only seasonal in lower highlands of Chiriquí ranges.

Status and Conservation. Not globally threatened. CITES II. Common and widespread in deforested areas throughout Caribbean slope of Costa Rica, increasing with forest clearance. Locally common and spreading E in Panama. Apparently always uncommon in international trade.

Bibliography. Anon. (1983), Blake (1958), Delgado (1985a), Eisenmann (1957), Hernández-Baños *et al.* (1995), Low (1972), Ridgely (1981), Ridgely & Gwynne (1989), Slud (1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Taylor, K. (1993), Wetmore (1968), Whitney (1996).

214. White-eyed Parakeet

Aratinga leucophthalmus

French: Conure pavoane **German:** Pavausittich **Spanish:** Aratinga Ojiblanca

Other common names: White-eyed Conure

Taxonomy. *Psittacus leucophthalmus* P. L. S. Müller, 1776, Guiana.

May form a superspecies with *A. finschii*, with which has been considered conspecific. Proposed race *propinquus* probably represents southern populations of a cline of increasing size. Nominate race intergrades throughout C Amazonia with race *callogenus*. Three subspecies recognized.

Subspecies and Distribution.

A. l. nicefori Meyer de Schauensee, 1946 - Meta, E Colombia.

A. l. callogenus (Salvadori, 1891) - SE Colombia, E Ecuador, NW Peru and extreme NW Brazil into C Amazonia.

A. l. leucophthalmus (P. L. S. Müller, 1776) - E Venezuela and the Guianas through virtually all Brazil to N & E Bolivia, Paraguay, N Argentina and N Uruguay.

Descriptive notes. 32-35 cm; 100-218 g. Green, paler below; some red flecking on head and neck; bare orbital ring greyish white; bend and edge of wing and outermost lesser underwing-coverts red; outermost greater underwing-coverts yellow; undersides of flight-feathers and tail olive. Immature mostly lacks red in wing. Race *callogenus* is larger and darker with thicker bill, and tends to be darker green in W; *nicefori* has red band across forehead.

Habitat. Forest edge and adjacent savanna, scrub forest, secondary growth, deciduous or gallery woodland. *Mauritia* palm groves in

llanos, seasonally flooded *várzea* forest along rivers, and openings in rain forest; also mangroves. Generally in lowlands, although up to 2500 m in Bolivia.

Food and Feeding. Fruit, e.g. of *Goupia glabra*, *Tetragastris altissima*, *Allanotoma lineata*, *Norantea guianensis*, *Fagura* and palms, blossoms of *Erythrina* and *Ficus frondosa*, grass seeds and even insects.

Breeding. Feb in the Guianas; possibly Jul-Aug in Peru; Jan-Mar in SW Brazil; around Nov in Argentina. Nest in hole in tree, sometimes high up; also in palm. Eggs 3-4; in captivity, incubation lasts 4 weeks, and nestling period 9 weeks.

Movements. Appears in thousands at one locality in French Guiana in Jun-Aug in response to palm fruiting.

Status and Conservation. Not globally threatened. CITES II. Common over much of enormous range, perhaps most numerous in W Amazonia and least so at N edges of range, being very local in Surinam and relatively so in French Guiana; also scarce in Uruguay. Present in Manu National Park, Peru, where density reaches 3 pairs/km². Regarded in 1970's as uncommon in captivity, even in South America, but 31,169 exported from Argentina, 1985-1990, interpreted as a serious threat to the species in that country. Heavily traded in Venezuela but this not considered serious.

Bibliography. Belton (1984), Canevari *et al.* (1991), Contreras *et al.* (1990), Desenne & Strahl (1991, 1994), Gore & Gepp (1978), Haffer & Fitzpatrick (1985), Harris (1992a), Haverschmidt & Mees (1994), Hayes (1995), Hilty & Brown (1986), Klimaitis & Moschione (1987), López (1992), Low (1972), Meise (1974), Meyer de Schauensee & Phelps (1978), Nores & Yzurieta (1994), Olmos (1993), O'Neill (1981), Orfila (1936), de la Peña (1988), Ridgely (1981), da Rocha *et al.* (1988), do Rosário (1996), Roth (1984a), Schubart *et al.* (1965), Short (1975), Sick (1985, 1993), Snyder (1966), Stotz *et al.* (1996), Terborgh *et al.* (1990), Torrano (1990), Tostain *et al.* (1992), Vriend (1979), Whitney (1996).

215. Cuban Parakeet

Aratinga euops

French: Conure de Cuba

German: Kubasittich

Spanish: Aratinga Cubana

Other common names: Cuban Conure

Taxonomy. *Sittace euops* Wagler, 1832, Cuba.

May form a superspecies with *A. chloroptera*. Monotypic.

Distribution. Cuba; formerly also I of Pines.

Descriptive notes. 26 cm. Green, more yellowish below; red flecks on head and underparts; bare orbital ring white; edge of wing and lesser underwing-coverts red; greater underwing-coverts and undersides of flight-feathers and tail olive yellow. Immature has less red on wings.

Habitat. Savannas, notably where rich in *Copernicia* and *Thrinax* palms, cultivated land with groves, woodland edge, but apparently with requirement to be near larger tracts of original forest.

Food and Feeding. Fruit and/or seeds of *Xanthoxylon*, *Terminalia*, *Melicoccus*, *Roystonea regia*, *Spondias lutea*, *Cordia allcococca*, *Inga*

vera, mangoes, papaya and guava; on I of Pines shoots of *Pinus caribbaea* and palm nuts. Formerly a crop pest, taking flowers and fruit of oranges, heads of maize, and berries of coffee.

Breeding. Apr-Jul. Nest in hole in tree including palms such as *Sabal palmetto*, often originally excavated by Cuban Green Woodpecker (*Xiphidiopicus percussus*), including those in arboreal termitaria. Eggs 3-5; incubation lasts 22-23 days; nestling period 45-50 days.

Movements. Flocks reported to descend occasionally from Trinidad mountains in Sept and Oct.

Status and Conservation. **VULNERABLE.** CITES II. Formerly abundant and one of the most numerous of Cuba's endemic birds, when greatly persecuted as a crop pest. This combined with extensive trapping for the cagebird trade, originally for internal consumption but increasingly for Eastern European markets in the period 1960-1990, and with increasing loss of primary forest, has resulted in a catastrophic collapse in population. The species probably persists in moderate numbers in several relatively inaccessible areas, and at its current greatly reduced levels it may now be stable. There are, however, very few protected areas in which populations occur, the most notable being Ciénaga de Zapata National Park. Extinction on I of Pines occurred around the start of 20th century, although there have been later reports of possible sightings.

Bibliography. Abreu *et al.* (1989), Acosta & Mugica (1988), Alayón (1987), Alayón *et al.* (1987), Alfonso *et al.* (1988), Anon. (1983), Balat & González (1982), Barbour (1923, 1943), Bauer (1989), Beissinger & Snyder (1992), Berovides *et al.* (1982), Bond (1985), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Davis (1941b), Garrido (1980), Garrido & García (1975), Low (1972, 1994b),

de las Pozas & González (1984b), Ripley & Watson (1956), Robiller (1990), Rutten (1934), Schneider (1997), Silva, T. (1981), Stotz *et al.* (1996), Sulley & Sulley (1992), Whitney (1996), Wiley (1991b).

216. Hispaniolan Parakeet

Aratinga chloroptera

French: Conure maîtresse

German: Haitisittich

Spanish: Aratinga de la Española

Other common names: Hispaniolan Conure

Taxonomy. *Psittacara chloroptera* Souancé, 1856, Santo Domingo.

Extremely close in appearance and size to *A. leucophthalmus*, and arguably conspecific, although possibly better regarded as a member of an enlarged *A. leucophthalmus* superspecies; may form a superspecies with *A. euops*. Race *maugei* of Mona I (off Puerto Rico) extinct. One extant subspecies recognized.

Subspecies and Distribution.

A. c. chloroptera (Souancé, 1856) - Hispaniola.

Descriptive notes. 32 cm. Green, more yellowish below; some birds show a few red flecks on head; bare orbital ring white; bend and edge of wing and outermost underwing-coverts red; undersides of flight-feathers and tail dull yellowish. Immature has less or lacks red in wing. Extinct race *maugei* barely distinct; duller below, with more red in greater underwing-coverts.

Habitat. All habitats from arid lowlands to more humid montane formations, commonest in latter.

Food and Feeding. Little specific information; noted feeding on *Ficus* fruits, and reported as

a pest on maize crops.

Breeding. No dates given. Nest in arboreal termitarium or hole in tree, in one case 25 m up in a dead pine.

Movements. No information.

Status and Conservation. **VULNERABLE.** CITES II. A BirdLife "restricted-range" species. Formerly (e.g. in 1920's) abundant, and until recently not recognized as at risk, but now believed to be very rare with a status possibly far worse than implied by "Vulnerable"; although reputedly still reasonably common in Sierra de Baoruco in Dominican Republic, observations in past few years have resulted in virtually no records (apparent presence of introduced *A. nana* making situation more difficult to judge). Habitat loss, persecution as a crop pest and use in local and international trade are all assumed to have had an impact. Extinction on Mona I attributed to pigeon hunters.

Bibliography. Anon. (1983), Bond (1928a, 1946, 1985), Collar (1996), Collar *et al.* (1994), Danforth (1929), Greenway, J.C. (1967), Dod (1992), Lever (1987), Low (1972, 1991f), Raffaele (1989), Silva (1984, 1988), Stotz *et al.* (1996), Wetmore & Swales (1931), Whitney (1996), Wiley (1991b).

217. Sun Parakeet

Aratinga solstitialis

French: Conure soleil

German: Sonnensittich

Spanish: Aratinga Sol

Other common names: Sun Conure

Taxonomy. *Psittacus solstitialis* Linnaeus, 1758, Guinea; error = Cayenne.

Sometimes treated as conspecific with *A. jandaya* and *A. auricapilla*, but perhaps better regarded as forming a superspecies with these forms. Possible intergradation with *A. jandaya* on lower Amazon (where range limits uncertain) may simply reflect age and individual variation. Monotypic.

Distribution. Guyana, Surinam and N Brazil; one record from French Guiana; a record reported from SE Venezuela now known to have been inside Brazil.

Descriptive notes. 30 cm. Like *A. jandaya* but with more orange-red on face, less on belly, where yellow extends to vent and thighs; yellow also extends onto back, rump, shoulder and median coverts. Immature replaces much yellow with green.

Habitat. Open savanna and savanna woodland, forested valleys, seasonally flooded (*várzea*) forest and secondary vegetation.

Food and Feeding. Very little information. Records include leguminous fruits, small melostomaceous fruits, red fruits of cacti, with birds observed among but not certainly feeding on *Malpighia* berries.

Breeding. Nest with nestlings in a *Mauritia flexuosa* palm in Feb, Surinam. In captivity: 4 eggs; incubation, by female only, 4 weeks; nestling period around 8 weeks.

Movements. Unclear if movements represent nomadism or seasonal pattern based on food availability, but population on lower Amazon apparently present throughout year.

Status and Conservation. Not globally threatened. CITES II. Immense flocks recorded by R. Schomburgk in NW of range, 1840's, but review of all evidence suggests it is much less common bird than was previously believed. Levels of international trade not excessive in period 1978-1985, but given the great beauty of this species and the notorious internal market for parrots in Brazil there may be a significant undetected influence from trapping.

Bibliography. Freud (1991a), Haverschmidt & Mees (1994), Inskipp *et al.* (1988), Joseph (1992a), Low (1972), Machado & Kwall (1975), Meyer de Schauensee & Phelps (1978), Nieremberg (1972), Niles (1981), Pinto (1964), Ridgely (1981), de Ruiter (1995), Sick (1985, 1993), Siebels & McCullough (1978), da Silva, J.M.C. & Willis (1986), Silva, T. (1993c), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Wheatley (1994), Whitney (1996).

218. Jandaya Parakeet

Aratinga jandaya

French: Conure jandaya

German: Jendayasittich

Spanish: Aratinga Jandaya

Other common names: Jandaya Conure, Yellow-headed/Flaming Parakeet

Taxonomy. *Psittacus Jandaya* J. F. Gmelin, 1788, Brazil.

Sometimes treated as conspecific with *A. solstitialis* and *A. auricapilla*, but perhaps better regarded as forming a superspecies with these forms. Monotypic.

Distribution. NE Brazil from E Pará and Goiás to Alagoas.

Descriptive notes. 30 cm. Head and neck yellow with orange-red over bill, round eyes, on throat, breast and belly; back and wings green with primary coverts, secondaries and tips of primaries dark blue; underwing-coverts orange-red; rump and upper tail dull greenish gold, uppertail terminally blue; undersides of flight-feathers and tail grey. Immature greener and duller.

Habitat. Like *A. auricapilla* tied to wooded cover, thus present in humid forest edge, ridge-top groves, coconut plantations, dry woodland and adjacent open areas, including farmland and pastures; appears to avoid

more arid vegetation including *caatinga*. On periphery of Belém, birds use 2-10 m high secondary growth.

Food and Feeding. Birds in Belém observed to feed on fruits of certain Melastomataceae, mango (*Mangifera indica*), caraná (*Mauritia huebneri*) and various *Cecropia*, plus cultivated maize and rice.

Breeding. Aug-Dec in Belém area; Dec elsewhere. Nest in natural or woodpecker hole in trees at least 15 m tall; distance between nests c. 50 m in Belém. In captivity: 3 eggs; incubation, by female only, lasts c. 26 days; nestling period around 8 weeks; in wild 55-60 days noted to elapse between nest preparation and fledging of young.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Relatively common and apparently increasing in numbers and range with clearance of continuous forest at E Amazon fringe; however, some evidence also of decrease in S Maranhão. Moreover, effects of trade poorly understood, although this is one of the most prized of South American parrots: no documentation exists of exploitation for internal consumption (although Brazil has notoriously strong community of bird-fanciers), and there is a suspicion that there are high levels of smuggling to SE Asia. Birds were formerly smuggled to Argentina for export (3600 in 1987) but this route closed since 1993.

Bibliography. Anon. (1993), Collar *et al.* (1992), Forrester (1993), Gould & Gould (1991), Harris & Harris (1983), Harrison & Holyoak (1970), Jones (1955), Lamm (1948), Low (1972), Machado & Kawall (1975), Pinto (1964), Ridgely (1981), Ruschi (1979), Saibene (1994), Schubert *et al.* (1965), Sick (1985, 1993), da Silva & Oren (1990), Stager (1961), Stotz *et al.* (1996), Vriends (1979), Whitney (1996).

219. Golden-capped Parakeet

Aratinga auricapilla

French: Conure à tête d'or **German:** Goldkopfsittich **Spanish:** Aratinga Testadorada
Other common names: Golden-capped Conure, Flame-capped Parakeet

Taxonomy. *Psittacus auricapillus* Kuhl, 1820, Bahia.

Sometimes treated as conspecific with *A. solstitialis* and *A. jandaya*, but perhaps better regarded as forming a superspecies with these forms. Two subspecies recognized.

Subspecies and Distribution.

A. a. auricapilla (Kuhl, 1820) - N & C Bahia, CE Brazil.

A. a. aurifrons Spix, 1824 - S Bahia S to Paraná, E Brazil.

One record from Paraguay in 1918 may have concerned escaped cage-birds.

Descriptive notes. 30 cm; 130 g. Area around eye onto forehead red, shading through orange on forecrown to yellow on mid-crown; bare orbital skin dark; head, body and wings fairly deep green, more yellowish below, with lower breast to belly red, lower back and rump edged with red, flight-feathers with blue, underwing-coverts orange-red, undersides of tail dull reddish grey. Immature has less red and yellow on head. Race *aurifrons* deeper green below and without red edging on back and rump.

Habitat. Fringes of semi-deciduous forests, being less common in second growth and pastureland with interspersed trees and palms,

but spreading out from shelter of good forest patches to forage in much more open areas including agricultural land, ranging as high as 2180 m.

Food and Feeding. Fruits and seeds, although only specific items recorded are cultivated plants such as okra and maize. When common in last century it was a crop pest.

Breeding. Almost no information. General evidence suggests breeding around Oct.

Movements. No information available, but some movements in response to food availability seem likely.

Status and Conservation. **VULNERABLE.** CITES II. In nineteenth century a common species; possibly in decline for two hundred years with steady and now extensive clearance and fragmentation of its habitat, and perhaps owing to trade for internal markets. Now seemingly very scarce throughout S part of range, with centre of abundance in Minas Gerais, but both forest clearance and trapping for local consumption continue unchecked. Recorded from Chapada Diamantina and Monte Pascoal National Parks (Bahia), Caratinga Reserve, Rio Doce State Park and Serra da Canastra National Park (Minas Gerais).

Bibliography. Anon. (1993), Beissinger & Snyder (1992), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Descourtiz (1983), Forrester (1993), Hayes (1995), Inskipp *et al.* (1988), Low (1972), Pinto (1935, 1964), Ridgely (1981), do Rosário (1996), Sick (1985, 1993), Stotz *et al.* (1996), Wege & Long (1995), Whitney (1996).

220. Dusky-headed Parakeet

Aratinga weddellii

French: Conure de Weddell **German:** Weddellsittich **Spanish:** Aratinga Cabecifusca
Other common names: Dusky-headed Conure, Weddell's Parakeet

Taxonomy. *Conurus Weddellii* Deville, 1851, Pebas, upper Amazon. Monotypic.

Distribution. SE Colombia S through E Ecuador, E Peru and NW Brazil to NE Bolivia.

Descriptive notes. 28 cm; 96-129 g. Head and sides of neck brownish grey with feathers tipped bluish grey, giving slight scaled effect; bare orbital ring yellowish white; breast grass green shading to lemon yellow on belly and thighs, shading green on vent; nape to rump green with vague dusky markings; wings green with outer secondaries, primary coverts and primary tips dark blue; tail green tipped dark blue. Immature similar.

Habitat. Seasonally flooded *várzea* forest, riparian growth, tall swampy second growth, scrublands and clearings, generally avoiding *terra firme* forest; also reported in cane and

coffee plantations. Lowlands to 750 m.

Food and Feeding. Poorly documented. Fruits of palms, *Goupia glabra*, *Inga edulis*, *Mimosa*, blossoms and inflorescences such as of *Erythrina* and *Dioeclea glabra*.

Breeding. Evidently Jun-Aug throughout range, with possible further record in Feb, Colombia: Apr-Jun in E of range in Brazil. Nest in hole in dead tree or arboreal termitarium, usually adjacent to water; pair witnessed enlarging old woodpecker hole. In captivity: 3-4 eggs; incubation, by female only, 23 days; nestling period 50 days.

Movements. Formation of large flocks at particular food sources suggests at least local displacements in response to changes in supply.

Status and Conservation. Not globally threatened. CITES II. Common in most of range, even in degraded and settled areas; evidence indicates a steady increase with clearance of continuous forest and construction of roads through such terrain. Traded in moderate numbers up to mid-1980's, with 17,195 exported by Bolivia in 1980-1983, but currently banned from export in all range states.

Bibliography. Allen (1995), Arndt (1980a), Bond & Meyer de Schauensee (1943), Hilty & Brown (1986), Inskipp *et al.* (1988), Low (1972), Nicholls (1983, 1994), O'Neill (1974, 1981), O'Neill & Pearson (1974), Parker *et al.* (1982), Pearson (1972, 1975c), Pinto (1964), Ridgely (1981), Roth (1984a), de Ruiter (1994a), Scott (1997), Sick (1985, 1993), Stotz *et al.* (1996), Terborgh & Weske (1969), Whitney (1996).

221. Olive-throated Parakeet

Aratinga nana

French: Conure aztèque **German:** Aztekensittich **Spanish:** Aratinga Pechusica
Other common names: Olive-throated Conure, Jamaican Parakeet/Conure (*nana*), Aztec Parakeet/Conure (*astec*)

Taxonomy. *Psittacara nana* Vigors, 1830, Jamaica.

Curiously disjunct distribution largely accounts for frequent treatment of race *astec* as distinct species, incorporating race *vicinialis*. Three subspecies normally recognized.

Subspecies and Distribution.

A. n. vicinialis (Bangs & Penard, 1919) - NE Mexico.

A. n. astec (Souancé, 1857) - Caribbean slope from SE Mexico to W Panama.

A. n. nana (Vigors, 1830) - Jamaica.

Descriptive notes. 22-26 cm; 72-85 g. Green, yellow on ear-coverts and rump; bare orbital skin white; throat and breast olive brown, shading to olive on belly and vent; outer webs of flight-feathers dull blue; flight-feathers grey below; tail yellowish below. Immature similar. Race *astec* paler and has smaller bill; *vicinialis* brighter than *astec* with greener tone in undersides.

Habitat. Dense humid forest and edge, deciduous woodlands (probably main habitat), pine stands, riparian vegetation, scrublands, plantations, clearings with groves, in coastal plains and foothills. Least common in humid forest in Central

America, where extends up to 1100 m; commonest in Jamaica in mid-level wet limestone forests.

Food and Feeding. Fruit of figs, *Inga*, *Hura* and *Hieronyma*; some melastomes; flowers of *Cannabis sativa*, Jamaica. Earlier reports mention nanchi and guava fruits. Often cause damage to crops, notably maize.

Breeding. Mar in Jamaica; Apr-May in Belize and Guatemala. Nest in cavity in termitarium, often excavated by the birds themselves, and often along riverbank or at forest edge. Eggs 3-5.

Movements. On Jamaica noted to visit arid S forests when certain food available, but otherwise absent; such responses to food supply seem likely to occur elsewhere. Records from W Panama appear to represent wanderers from Costa Rica, where much less common and perhaps only seasonal S of Limón.

Status and Conservation. Not globally threatened. CITES II. Much the commonest parrot in Yucatán, 1950's, and generally at least locally common throughout its range, but with some local declines, also believed on Jamaica, in response to forest clearance. Persecuted as crop pest, Jamaica. Uncommon in international trade.

Bibliography. Binford (1989), Bond (1985), Clinton-Eitniece (1984a), Clinton-Eitniece *et al.* (1989), Downer & Sutton (1990), González-García (1993), Hardy (1966), Hess (1997), Howell & Webb (1995a), Inskipp *et al.* (1988), Land (1970), Latta *et al.* (1997), Low (1972), Lowery & Dalquest (1951), Monroe (1968), Parkes (1976), Paynter (1955), Ridgely (1981), Ridgely & Gwynne (1989), Russell (1964), Slud (1964), Smith, P.W. (1996), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1968), Whitney (1996), Wiley (1991b).

222. Orange-fronted Parakeet

Aratinga canicularis

French: Conure à front rouge **German:** Elfenbeinsittich **Spanish:** Aratinga Frentinaranja
Other common names: Orange-fronted Conure

Taxonomy. *Psittacus canicularis* Linnaeus, 1758, north-western Costa Rica. Forms a superspecies with *A. aurea*. Three subspecies recognized.

Subspecies and Distribution.

A. c. clarae R. T. Moore, 1937 - W Mexico from Sinaloa to C Michoacán.

A. c. eburnirostrum (Lesson, 1842) - SW Mexico from E Michoacán to Oaxaca.

A. c. canicularis (Linnaeus, 1758) - Pacific coast and foothills from S Mexico (Chiapas) to W Costa Rica.

Descriptive notes. 23-25 cm; 68-80 g. Forehead to lores orange-peach; mid-crown dull blue; bare orbital ring yellow; hindcrown, nape, back and wings dull green; throat and breast pale olive brown; belly to vent yellowish green; flight-feathers show blue; tail green above, yellowish below. Immature has reduced orange-peach on forehead. Race *eburnirostrum* with narrower orange-peach forehead, greener below with brown spot on base of lower mandible; *clarae* with orange-peach reduced to narrow band, throat and breast greener, bill spot black.

Habitat. Forest edge, deciduous woodland, Pacific swamp forest, savannas and arid thorn scrub, adapting well to areas partly opened up for pasture and travelling to rest in plantations of mangoes and palms often near urban areas; chiefly in lowlands but ranging up to 1500 m.

Food and Feeding. Fruits, e.g. *Ficus*, *Bursera*, *Brosimum*; flowers, e.g. *Gliricidia*, *Combretum*; and seeds, e.g. *Ceiba*, *Inga*. Wandering flocks can cause serious damage to young maize and ripening bananas.

Breeding. Jan-May in Mexico and El Salvador; dry season in Costa Rica. Nest in cavity in arboreal termitarium of *Nasutitermes nigricipes*, usually excavated by the birds themselves, sometimes in old woodpecker hole or natural fissure. Eggs 3-5; incubation, by female only, lasts c. 30 days; nestling period about 6 weeks.

Movements. Forms larger flocks and shows nomadism outside breeding season, wandering to much higher elevations.

Status and Conservation. Not globally threatened. CITES II. With *Amazona albifrons* the most numerous parrot on Pacific slope of Middle America. Apparently little affected by habitat destruction; relatively low levels of international trade. However, in many areas of Costa Rica population has decreased owing to pet trade (perhaps mainly for domestic consumption), and decline in El Salvador also noted.

Bibliography. Anon. (1983), Binford (1989), Chapman *et al.* (1989), Clifton (1994), Dickey & van Rossem (1938), Hardy (1963, 1965, 1966), Howell & Webb (1995a), Inskipp *et al.* (1988), Land (1970), Lever (1987), Low (1972), McLellan (1927), Monroe (1968), Paynter (1956), Raiffaie (1989), Ridgely (1981), Rowley (1966), Schaldach (1963), Slud (1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Tashian (1953), Thurber (1978), Wetmore (1941a, 1944), Whitney (1996), Zimmerman & Harry (1951).

223. Peach-fronted Parakeet

Aratinga aurea

French: Conure couronnée **German:** Goldstirnsittich **Spanish:** Aratinga Frentidorada
Other common names: Peach-fronted Conure, Golden-crowned Parakeet/Conure

Taxonomy. *Psittacus aureus* J. F. Gmelin, 1788, Bahia.

Forms a superspecies with *A. canicularis*. Proposed race *major* probably represents S populations of a cline of increasing size. Monotypic.

Distribution. S Surinam through N, C & interior S Brazil to SE Peru, E Bolivia, Paraguay and N Argentina.

Descriptive notes. 23-28 cm; 74-94 g. Forehead to mid-crown peachy orange separated from pale orange bare orbital ring by line of dull green that extends below and behind eye onto rest of upperparts, wings and tail; hindcrown dull blue; cheeks and underparts pale olive-brown, shading greenish yellow on vent and undertail-coverts; greenish blue in flight-feathers. Differs from *A. canicularis* in colour of bill, and of throat and breast. Immature has less orange and blue on head.

Habitat. Tropical savanna with *Mauritia* palm groves, gallery forest, *cerrado*, remnant woodlots adjacent to agricultural land and even

urban areas, savanna-like "campo rupestre" with many shrubs, herbs and scattered trees, moving between wooded areas and open grassland habitats to forage. Lowlands to 600 m.

Food and Feeding. Much foraging done on ground. Seeds (but not pulp) of *Ilex*, *Banisteriosis*, *Campomanesia adamantinum*, *Eucalyptus*, *Symplocos* and *Aegiphylia*, flowers of *Qualea*, *Caryocar brasiliensis* and *Tabebuia*, pulp of *Anacardium*, and leaves (mandibulated but perhaps not ingested) of *Vochysia thyrsoidea* and *Ocotea*. Sometimes also termites and the larvae of flies, beetles and moths. Gleans harvested fields for soya beans, rice and maize, and can cause damage prior to harvesting.

Breeding. Jun-Jul in SE Peru; Sept-Dec in C Brazil. Nest excavated upwards into termitarium, either on ground or in *cerrado* tree. Eggs 2-4; in captivity, incubation lasts 23 days, nestling period 48 days.

Movements. Some local movements seem likely in response to food availability, but nothing recorded.

Status and Conservation. Not globally threatened. CITES II. Common in Sipaliwini savanna, Surinam, and abundant in *campos cerrados*, Paraguay. Across most of Brazil it is the commonest *Aratinga* and may be increasing with the clearance of blocks of more humid forest for agriculture, but suffers extensively from taking of nestlings for sale as pets, with very high mortality in rearing stages. In 1985-1989 45,154 birds were exported from Argentina, but these must have been smuggled in from Brazil for the purpose as the species, although once common, is now rare in Argentina (two records since 1956), for reasons unknown; it is still officially on the list of pest species.

Bibliography. Antas & Cavalcanti (1988), Canevari *et al.* (1991), Cherrie & Reichenberger (1923), Contreras *et al.* (1990), Darrieu (1979), Galetti & Pedroni (1996), Graham *et al.* (1980), Hadgkiss (1978), Haverschmidt & Mees (1994), Hayes (1995), Inskipp *et al.* (1988), López (1992), Low (1972), Norees & Yzurieta (1994), O'Neill (1981), Olrog (1958), de la Peña (1988), Pinto (1964), Ridgely (1981), do Rosário (1996), Szima (1989), Schubart *et al.* (1965), Short (1975), Sick (1985, 1993), Stotz *et al.* (1996), Vriends (1979), Whitney (1996).

224. Brown-throated Parakeet

Aratinga pertinax

French: Conure cuivrée **German:** Braunwangensittich **Spanish:** Aratinga Pertinax
Other common names: Brown-throated Conure, Caribbean Parakeet; Veragua's Parakeet (*ocularis*)

Taxonomy. *Psittacus pertinax* Linnaeus, 1758, Curaçao.

Forms a superspecies with *A. cactorum*. Considerable geographical variation reflected in number of subspecies recognized, although some differences are minor and very possibly clinal in nature. Disjunct form *ocularis* sometimes treated as separate species. Fourteen subspecies currently recognized.

Subspecies and Distribution.

A. p. ocularis (P. L. Sclater & Salvin, 1864) - Panama.

A. p. aeruginosa (Linnaeus, 1758) - N Colombia to NW Venezuela.

A. p. griseipecta Meyer de Schauensee, 1950 - Sinú Valley, NE Colombia.

A. p. lehmanni Dugand, 1943 - E Colombia E possibly into W Venezuela.

A. p. arubensis (Hartert, 1892) - Aruba (Netherlands Antilles).

A. p. pertinax (Linnaeus, 1758) - Curaçao (Netherlands Antilles).

A. p. xanthogenia (Bonaparte, 1850) - Bonaire (Netherlands Antilles).

A. p. tortugensis (Cory, 1909) - I Tortuga (Venezuela).

A. p. margaritensis (Cory, 1918) - I Margarita (Venezuela).

A. p. venezuelae Zimmer & Phelps, 1951 - Venezuela except NW, possibly W, extreme NE & SE.

A. p. surinama Zimmer & Phelps, 1951 - NE Venezuela and the Guianas.

A. p. chrysophrys (Swainson, 1838) - SE Venezuela and adjacent Brazil.

A. p. chrysogenys (Massena & Souancé, 1854) - R Negro, NW Brazil; possibly this form recently near Mamirauá Reserve on R Solimões.

A. p. paraensis Sick, 1959 - R Tapajós and R Cururu, NC Brazil.

Introduced (*pertinax*) to St Thomas (Virgin Is).

Descriptive notes. 25 cm; 76-102 g. Forehead, face and chin yellow; breast dull olive; belly grass green with orange patch; mid-crown and rest of upperparts green; flight-feathers and tail edged and tipped dullish blue. Immature largely lacks yellow. Race *xanthogenia* has orange-yellow extending onto crown and nape; *arubensis* mixes brown on yellow face; *aeruginosa* as previous race, with buff forehead; *griseipecta* as last but cheeks and breast olive-grey; *lehmanni* as *aeruginosa* but more orange-yellow round eye; *tortugensis* as *aeruginosa* but more orange-yellow on sides of head; *margaritensis* has whitish forehead and

face olive-brown; *venezuelae* as last but more yellowish above; *chrysophrys* as *margaritensis* but face richer brown; *surinama* as last but more orange below eye and breast greener; *chrysogenys* darker than others with no frontal band; *paraensis* as last with orange-yellow belly; *ocularis* similar to *margaritensis* but paler, with no frontal band.

Habitat. Savannas and semi-open arid scrubby areas with cacti and acacias, also mangrove woodland, tropical deciduous forest, gallery and white sand forest, rhizophore mangroves, edges of humid evergreen forest, cultivated areas and pastures where groves of palms and other trees remain; lowlands to 1200 m.

Food and Feeding. Up to 70% of food plants used, NW Venezuela, were planted by man: seeds of *Cassia*, *Peltophorum*, *Lagerstroemia*, *Cedrela*, fruit of *Mangifera*, *Muntingia*, *Swietenia*, *Psidium*, *Solanum*, flowers of *Tabebuia*, *Delonix*, *Erythrina*, *Gliricidia*, and leaves of *Spathodea*; elsewhere, *Caesalpinia*, *Acacia*, *Prosopis*, *Cereus*, *Malpighia*, *Fagara*, *Curatella* and *Cochlospermum* also recorded. Reportedly a crop pest on maize, Colombia, and known as such, Netherlands Antilles, where also a regular visitor to fruit plantations.

Breeding. Feb-Apr in E Colombia and NW Venezuela, although Oct-Apr also noted for latter area; almost throughout year in Surinam, where nests found Jan-Mar, Jun-Sept, and Nov; similarly in Netherlands Antilles. Nest in hole excavated in arboreal termitarium, particularly that of genus *Nasutitermes*, sometimes in palm stub or tree with natural cavity, or in cliff face, old wall, limestone cliff, cave, earth bank or seacoast rocks; often in small colonies, e.g. with several pairs using one rotten tree. Eggs 2-7 (9 once found in one nest, suggesting second female involved, although possibly only after first deserted); in captivity, incubation 23 days, probably by female only. Nestling period in wild only 36-37 days.

Movements. Some seasonal movement to more humid areas during driest months, Santa Marta area, Colombia. In Aragua, Venezuela, highest numbers occur in May-Sept probably in response to maize and sorghum harvest, birds moving in Nov-Apr to foothill woodlands and savannas, to breed.

Status and Conservation. Not globally threatened. CITES II. Locally common, Panama. Most numerous parrot in Caribbean lowlands and llanos in Colombia and in Guyana and N Surinam, and abundant on all three of Netherlands Antilles. In one area of NW Venezuela a density of 5-89 birds/km² has been estimated. Some evidence that mainland populations are expanding their ranges in response to forest clearance for ranchland. Little exploited for international trade, although local pressure heavy in Venezuela, with two island races, *margaritensis* and *tortugensis*, particularly affected (the former is still very numerous, while the latter is not and is exposed to severe climatic

fluctuations that affect its status); birds also persecuted in Venezuela as pests of maize, sorghum, sesame and sunflower crops.

Bibliography. Albornoz & Fernández-Badillo (1994a, 1994b), Bond (1985), Burkard & Ender (1983), Desenne & Strahl (1991, 1994), Dugand (1947), Fernández-Badillo *et al.* (1994), Friedmann (1948b), Haverschmidt & Mees (1994), Hilty & Brown (1986), Lever (1987), Low (1972), Meyer de Schauensee & Phelps (1978), Ridgely (1981), Ridgely & Gwynne (1989), Rodríguez & Rojas-Suárez (1994), Schäfer & Phelps (1954), Shore-Baily (1915), Sick (1985, 1993), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Voous (1983), Vriends (1979), Wetmore (1939, 1968), Whitney (1996), Wiley (1993).

225. Cactus Parakeet

Aratinga cactorum

French: Conure des cactus **German:** Kaktussittich **Spanish:** Aratinga Cactácea
Other common names: Cactus Conure, Caatinga Parakeet/Conure

Taxonomy. *Psittacus cactorum* Kuhl, 1820, south-eastern Brazil.

An arid-country representative of *A. pertinax*, possibly conspecific but probably better treated as forming a superspecies. Two subspecies recognized.

Subspecies and Distribution.

A. c. caixana Spix, 1824 - NE Brazil.

A. c. cactorum (Kuhl, 1820) - CE Brazil.

Descriptive notes. 25 cm. Forecrown, lores, throat, sides of neck and breast light brown; bare orbital ring whitish; ear-coverts, nape and upperparts green; flight-feathers bluish; belly to vent dull orange. Immature has green crown, underparts duller. Race *caixana* paler.

Habitat. Arid thorny *caatinga* vegetation dominated by shrubs and succulents, open woodland (*angical*) with *Anadenanthera macrocarpa*, and second-growth *caatinga* following cultivation or burning; also degraded pasture and less arid woodland.

Food and Feeding. No specific information; flower buds reported, also occasional damage

to crops such as rice and maize.

Breeding. No information from wild. In captivity: up to 6 eggs laid; incubation period as short as 16 days between last egg being laid and first hatching; nestling period 6 weeks.

Movements. No information, but some local movements in response to food availability seem likely.

Status and Conservation. Not globally threatened. CITES II. Generally common, often commonest psittacid, with little trade pressure. However, *caatinga* is poorly protected (0-1% of original area inside reserves) and being steadily degraded. The species occurs in Serra da Capivara National Park.

Bibliography. Forrester (1993), Harris & Harris (1982), Lamm (1948), Lovell-Keays (1914a, 1914b), Low (1972), Novaes (1992), Olmos (1993), Olrog (1968), Pinto (1964), Prante (1986), Ridgely (1981), Ruschi (1979), Sargeant & Wall (1996), Sick (1985, 1993), Stotz *et al.* (1996), Vriends (1979), Whitney (1996), Willis (1992).

Genus NANDAYUS Bonaparte, 1854

226. Nanday Parakeet

Nandayus nenday

French: Conure nanday **German:** Nandaysittich **Spanish:** Aratinga Ñanday
Other common names: Nanday Conure, Black-headed/Black-hooded Conure/Parakeet

Taxonomy. *Psittacus nenday* Vieillot, 1823, Paraguay.

Sometimes placed in *Aratinga*. Monotypic.

Distribution. SE Bolivia and SW Brazil through C Paraguay to N Argentina. Small numbers feral in Buenos Aires city; also in Canada and USA.

Descriptive notes. 32-37 cm; 120-141 g. Blackish face and crown with flesh-coloured periorbital area; yellowish green on cheeks, belly and underwing-coverts, a shade darker on nape, back, rump, upperwing-coverts and vent; breast light blue; thighs orange red; flight-feathers above blue, below dark; tail above olive green tipped blue, below dark. Immature has less blue on breast, shorter tail.

Habitat. Gallery forest, isolated deciduous woodlots and palm stands in Pantanal, open savanna country and pastures; also moist Chaco and low dry scrub. Up to 800 m or more.

Food and Feeding. Palm nuts, seeds, fruits,

berries, flowers and buds; often taken from the ground.

Breeding. Nov. Nest in wild prospected by up to 12 birds, in holes in trees and tops of fence posts in stockyards. Eggs 4; in captivity, 3 eggs, incubation 21-23 days, and nestling period c. 8 weeks.

Movements. Flocks may wander widely in non-breeding season, and the first confirmed record from Bolivia may have represented such a long-range movement from Pantanal 300 km to the E.

Status and Conservation. Not globally threatened. CITES II. Common to locally abundant, and in parts of Brazil the commonest parrot, with habitat little modified except by grazing; range in Paraguay and Argentina reportedly extending owing to land settlement and cultivation, and in Argentina (where present in Pilcomayo National Park) officially listed as a pest. CITES records show average 19,000 (minimum) exported 1985-1990, 99% reportedly from Argentina though most believed originating in Paraguay; this is regarded as excessive.

Bibliography. Anon. (1985b, 1993), Canevari *et al.* (1991), Contreras (1979b), Contreras *et al.* (1990), Fisk & Crabtree (1974), Hayes (1995), Inskipp *et al.* (1988), Kawata *et al.* (1977), Klimaitis & Moschione (1987), Kratter

et al. (1993), Lever (1987), López (1992), Low (1972), Naumburg (1930), Nores & Yzurieta (1994), de la Peña (1988), Ridgely (1981), Short (1975), Sick (1985, 1993), Steinbacher (1962), Stotz *et al.* (1996), Vriends (1979), Wetmore (1926), Whitney (1996).

Genus LEPTOSITTACA

Berlepsch & Stolzmann, 1894

227. Golden-plumed Parakeet

Leptosittaca branickii

French: Conure à pinceaux d'or **German:** Pinselsittich **Spanish:** Aratinga de Pinceles
Other common names: Golden-plumed Conure/Parrot

Taxonomy. *Leptosittaca branickii* Berlepsch and Stolzmann, 1894, Maraynioc. Monotypic.

Distribution. S Colombia in C Andes S through Ecuador to C Peru.

Descriptive notes. 35 cm. Green, with narrow frontal band orange, shading to yellow on lores, below white periorbital patch, and extending on elongated feathers behind eye; abdomen washed yellow with indistinct broad orange bars; flight-feathers yellowish below; tail dull green above, dull reddish below. Immature undescribed.

Habitat. Temperate cloud forest, stunted timberlines and elfin woodland, notably but not always *Podocarpus*-dominated areas, generally at 2400-3400 m although as low as 1400 m at times.

Food and Feeding. *Podocarpus* seeds commonly preferred, but also takes those of *Prumnopitys montanus* and *Croton*, plus fruits of *Ficus* and *Melastomataceae*, even reportedly cultivated maize.

Breeding. Feb in Colombia, with evidence for Aug in Ecuador. Pair seen apparently prospecting in holes in dead *Ceroxylon quindiuense* palms in May, Colombia. No other information.

Movements. Apparently highly nomadic, and commonly gregarious: the species may disappear from a forested region from which it has been known for years, only to reappear much later, but may also do this over much shorter time spans in some areas. This behaviour may be related to temporally patchy distribution of suitable *Podocarpus* cones.

Status and Conservation. **VULNERABLE.** CITES II. Heavy deforestation in N parts of range is a concern, particularly because the species appears to depend on unpredictable food resources and cannot be conserved with certainty in any one reserve. Recorded in Los Nevados, Munchique, Puracé, Cueva de los Guácharos National Parks, Ucumari Regional Park, Acaime Natural Reserve and Galeras and Isla la Corota Sanctuaries (Colombia), Río Mazan Reserve, Huashapampa Protection Forest and Podocarpus National Park (Ecuador) and Río Abiseo National Park (Peru). Unknown in trade.

Bibliography. Arndt (1986), Beissinger & Snyder (1992), Bloch *et al.* (1991), Butler (1979), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Davies *et al.* (1994), Fjeldså & Krabbe (1990), Flanagan & Galvez (1996), Hilty & Brown (1986), King (1989), Low (1972), Negret & Acevedo (1990), O'Neill (1981), Parker *et al.* (1982), Pulido (1991), Rasmussen *et al.* (1996), Ridgely (1981), Salaman & Gandy (1993), Stotz *et al.* (1996), Walker & Jacobs (1995), Wege & Long (1995), Whitney (1996), Williams & Tobias (1994).

Genus CYANOLISEUS Bonaparte, 1854

228. Burrowing Parakeet

Cyanoliseus patagonus

French: Conure de Patagonie **German:** Felsensittich **Spanish:** Loro Barranquero
Other common names: Patagonian Parrot/Conure/Parakeet, Burrowing Parrot

Taxonomy. *Psittacus patagonus* Vieillot, 1818, Buenos Aires.

Population of C Chile, formerly known as *byroni*, recently renamed *bloxami*, following the realization that the name *byroni* actually refers to (and is a synonym of) *Enicognathus leptorhynchus*. Four subspecies recognized.

Subspecies and Distribution.

C. p. andinus Dabbene & Lillo, 1913 - NW Argentina.

C. p. conlara Nores & Yzurieta, 1983 - San Luis and Córdoba provinces, WC Argentina.

C. p. patagonus (Vieillot, 1818) - C to SE Argentina, ranging occasionally into Uruguay in winter.

C. p. bloxami Olson, 1995 - C Chile.

Descriptive notes. 39-52 cm; 256-303 g. Head to upper back and mid-belly dull olive, with bare white peri- and postocular patch, and a variable but incomplete dirty whitish pectoral band; belly and thighs variably orange red, flanks, upper thighs, vent, lower back and rump yellow; wing-coverts greenish olive, primaries bluish, secondaries and tail olive. Immature like adult with horn-coloured patch on mandible. Race *andinus* duller, olive yellow replacing yellow, pectoral band very indistinct; *conlara* darker on breast; *bloxami* larger with whitish pectoral band wider and more nearly complete, back darker green, but ventral red variable and not diagnostic.

Habitat. Arid lowland and montane grassy shrubland, open dry woodland savanna, open Chaco plains along watercourses, thorny scrub or columnar cacti, often with a sandy substrate, commonly near watercourses, up to 2000 m; also pastures and cultivation, and will enter edges of towns, roosting on wires. Dominant tree species in one study area were *Geoffroea decorticans*, *Prosopis caldenia*, *P. chilensis* and *P. flexuosa*.

Food and Feeding. Seeds taken from the ground, but also from standing vegetation such as the giant thistle *Carduus marianus*, these mostly in winter; berries and fruits such as *Geoffroea decorticans*, *Prosopis*, *Schinus*, *Empetrum rubrum*, *Lycium salsum*, *Discaria* and cacti, mostly in summer. Thus in one study, in terms of percentage of total volume, fruit comprised 2% of crop contents in Nov-Dec, 74% in Jan, 25% in Feb, 35% in Mar, and 8% in Apr.

Breeding. Sept-Feb. Nest in burrow in sandstone, limestone or earth cliff, often by river or sea, sometimes at considerable height; colo-

nial, with burrows often interconnecting. Eggs 2-4; in captivity, incubation timed at 24-25 days, nestling period 8 weeks. In wild, young dependent for several months after leaving nest.

Movements. Austral migrant in S of range, extending N in winter as far as coastal Uruguay. Downslope movements occur in winter in Chile and NW Argentina, and some nomadism may occur.

Status and Conservation. Not globally threatened. CITES II. Formerly very common but now only patchily so, and still declining in part owing to increasing persecution as crop pest (officially declared as such under Argentine law in 1984), and related exploitation for pet trade (pest status excluding it from the country's general 1986 ban on wildlife trade); its colonial nesting habit renders it particularly susceptible to intentional human interference. Up to 1991 export quotas were unlimited, but were set at 9000 in 1992 and 7200 in 1993, the race *andinus* being recommended for exclusion from this exploitation. Race *conlara* abundant within restricted range. Race *bloxami* formerly widespread and abundant, now much reduced in numbers, largely owing to hunting as a feast-day delicacy; by 1983 only 12 nesting sites were known, with 2800 birds in 1984. Hydroelectric damming threatened two of these sites, and translocation efforts with supplementary feeding were being attempted.

Bibliography. Anon. (1993), Brennan (1994), Bucher & Nores (1988), Bucher & Rinaldi (1986), Bucher & Rodríguez (1986), Bucher *et al.* (1987), Canevari *et al.* (1991), Clarke & Clarke (1994), Conway (1965), Fjeldså & Krabbe (1990), Goodland (1987), Hoy (1968), Inskipp *et al.* (1988), Johnson (1967, 1972), Jones (1992), Klimaitis & Moschione (1987), Low (1972, 1995a), Manríquez (1984), Moschione (1992), Narosky & di Giacomo (1993), Nellar (1993), Nores & Yzurieta (1983, 1994), Olrog (1984), Olson (1995), Partridge (1964), de la Peña (1988), Ridgely (1981), Silva (1985), Stotz *et al.* (1996), Wetmore (1926), Whitney (1996), Wilkinson (1991).

PLATE 49

inches 4
cm 10

Genus *PYRRHURA* Bonaparte, 1856

229. Blue-throated Parakeet

Pyrrhura cruentata

French: Conure tiriba **German:** Blaulatzsittich **Spanish:** Cotorra Tiriba
Other common names: Blue-chested/Ochre-marked/Red-eared/Black-tailed Parakeet/Conure, Blue-throated Conure

Taxonomy. *Psittacus cruentatus*, Wied, 1820, Rio de Janeiro. Monotypic.

Distribution. E Brazil from Bahia to Rio de Janeiro.

Descriptive notes. 30 cm. Crown and nape blackish with buff flecks; lores to ear-coverts orange red, yellower posteriorly; lower cheeks green; breast, sides of neck and thin collar blue; rest of body green but with red on belly, rump and bend of wing, blue in primaries, tail olive green above and brownish red below. Immature duller, less red in wing.

Habitat. Humid primary lowland forest and edge, penetrating small clearings and thinned forest, and tolerating shade plantations, reaching 960 m in some places, though generally below around 400 m.

Food and Feeding. Seeds and fruits of trees commonly at forest edges or in canopy; *Trema micrantha*, *Cecropia*, *Talisia esculenta*, *Alchornea iricurana* and *Mabea fistulifera* have been identified, and *Miconia hypoleuca* important as available in period of general fruit scarcity. Maize reported but not confirmed by observation.

Breeding. Sept-Dec. Nest in hole in tree, once 10 m up. Eggs 2-4; incubation 22-25 days; nestling period 45 days.

Movements. No evidence for any migration; indeed, ability to move between now highly disjunct forest fragments may be negligible.

Status and Conservation. **VULNERABLE.** CITES I. Survives in patches of forest in landscape largely cleared of trees over a century ago, yet even now forest (notably where left to shade understorey plantations in Bahia) is being cleared rapidly, leaving isolated populations stranded in a handful of reserves, those owned publically being: Chapada Diamantina and Monte Pascoal National Parks (Bahia), Rio Doce State Park (Minas Gerais), Córrego Grande, Córrego do Veado and Sooretama Biological Reserves (Espírito Santo).

Bibliography. Beissinger & Snyder (1992), Coimbra-Filho & Aldrichi (1971, 1972), Coimbra-Filho *et al.* (1973), Collar (1986, 1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Descourtiz (1983), Ferris (1996), Forrester (1993), Galetti & Stotz (1996), Gonzaga *et al.* (1987), Harrison & Holyoak (1970), King (1978/79), Low (1972), de Mattos & de Andrade (1988), Moojen *et al.* (1941), Pinto (1935, 1938, 1945a), Ridgely (1981), Scott & Brooke (1985), Sick (1972, 1985, 1993), Spenkelink-van Schaik (1984, 1996), Stotz *et al.* (1996), Tobias *et al.* (1993), Wege & Long (1995), Whitney (1996).

230. Blaze-winged Parakeet

Pyrrhura devillei

French: Conure de Deville **German:** Devillesittich **Spanish:** Cotorra de Deville
Other common names: Blaze-winged Conure

Taxonomy. *Conurus Devillei* Massena and Souancé, 1854, Bolivia (= Paraguay).

Forms a superspecies with *P. frontalis*, and may be conspecific, converging on *P. f. chiripepe*, with which hybridizes in N Paraguay. Monotypic.

Distribution. S Brazil and N Paraguay. The part of Bolivia from which the type specimen came appears now to be in Paraguay.

Descriptive notes. 26 cm. Like *P. frontalis* but crown brownish; bend of wing, carpal edge and lesser underwing-coverts red, and underparts darker. Immature undescribed.

Habitat. Deciduous and gallery woodland in the Pantanal and Chaco regions, ranging into adjacent scrub and savanna, seeming to occupy ecotones.

Food and Feeding. Fruit, seeds and nuts, in one case *Sapium haematospermum*.

Breeding. No information.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Although the range is relatively

small, it is remote and little disturbed, although recent development of the Pantanal for ranchland may have reduced some habitat. Birds reportedly remain locally common in Brazil, although rare and uncommon in Paraguay, while trade is apparently minimal.

Bibliography. Hayes (1995), López (1992), Low (1972), Olrog (1968), Pinto (1964), Remsen & Traylor (1989), Ridgely (1981), Short (1975), Sick (1985, 1993), Schubart *et al.* (1965), Stotz *et al.* (1996), Wheatley (1994), Whitney (1996), Zotta (1950).

231. Maroon-bellied Parakeet

Pyrrhura frontalis

French: Conure de Vieillot **German:** Braunoehrsittich **Spanish:** Cotorra Chiripepe

Other common names: Maroon-bellied Conure, Red-bellied/Reddish-bellied Parakeet/Conure

Taxonomy. *Psittacus frontalis* Vieillot, 1818, Cayenne; error, Espírito Santo.

Forms a superspecies with *P. devillei*, with which may be conspecific. Intermediate populations formerly placed in a separate race, *kriegi*. Two subspecies currently recognized.

Subspecies and Distribution.

P. f. frontalis (Vieillot, 1818) - E Brazil from Bahia to Rio de Janeiro and N São Paulo.

P. f. chiripepe (Vieillot, 1818) - SE Brazil, SE Paraguay and N Argentina.

Descriptive notes. 24-28 cm; 72-94 g. Generally green; frontal band rufous; lores black; ear-coverts reddish brown; chin to sides of neck and breast yellowish green edged brown, producing scaled effect; belly maroon; primaries with blue; tail olive green, distal third maroon, undersides dull rufous brown. Immature duller. Race *chiripepe* has no maroon on upper tail, bend of wing usually marked orange red.

Habitat. Range generally follows distribution of *Araucaria*, though link not strict: thus in N of range confined to humid montane evergreen forest, spreading in S into lower-lying areas of forest including drier formations, gallery wood-

land, partly cleared and thinned areas, even some city parks; 0-1400 m.

Food and Feeding. *Araucaria* nuts are a chief food in S Brazil, but also recorded are fruits of *Campomanesia xanthocarpa* and *Podocarpus lamberti*, palm nuts, *Myrciara* fruits, cultivated oranges and persimmons, maize, and homopteran larvae in galls. Detailed study in SE Brazil showed pulp of *Euterpe edulis*, seeds of *Schinus*, *Xylopia*, *Cecropia*, *Alchornea*, *Croton*, *Hieronyma*, *Tetrorchidium*, *Miconia*, *Tibouchina*, *Piptadenia*, *Coussapoa*, *Ficus*, *Myrcia*, *Psidium*, *Pinus*, *Merostachys*, *Solanum*, *Trema*, flowers of *Ambrosia*, *Piptocarpha*, *Vernonia*, *Norantea*, *Eucalyptus*, arils of *Protium*.

Breeding. Oct-Dec in S Brazil. Nest in hole in tree, once only 3 m from ground. Eggs 5; in captivity, incubation around 30 days, nestling period 45 days.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. In many parts of S Brazil it is one of the commonest parrots, and it is common in Misiones, Argentina, becoming rare at edges of range in Uruguay, and no recent records from Santa Fe, Argentina. In period 1985-1990 29,678 birds were exported from Argentina, which classified the species as an injurious pest, but no export quota was set in 1993 and for some years concern has existed that remaining populations should not suffer further exploitation in the country.

Bibliography. Anon. (1993), Belton (1984), Canevari *et al.* (1991), Contreras *et al.* (1990), Dalborg-Johansen (1954), Darrieu (1983c), Eckelberry (1965), Gore & Gepp (1978), Guix (1995), Hayes (1995), Inskipp *et al.* (1988), Klimaitis & Moschione (1987), López (1992), Low (1972), Martuscelli (1994a), Mitchell (1957), Nores & Yzurieta (1994), de la Peña (1988), Pizo *et al.* (1995), Ridgely (1981), do Rosário (1996), Saibene & Narosky (1983), Short (1975), Sick (1985, 1993), Stotz *et al.* (1996), Vriends (1979), Wetmore (1926), Whitney (1996), Willis & Oniki (1981).

232. Crimson-bellied Parakeet

Pyrrhura perlata

French: Conure à ventre rouge **German:** Rotbauchsittich **Spanish:** Cotorra Ventrirroja
Other common names: Crimson-bellied Conure

Taxonomy. *Aratinga perlatus* Spix, 1824, banks of the Amazon.

Forms a parapatric species pair with *P. lepida*, with which sometimes considered conspecific. Complicated situation in which types of name *perlata* have proved to be immatures of the form long known as *P. rhodogaster*, which name thus becomes a junior synonym of *P. perlata*; as a consequence, the form (Pearly Parakeet) until now known as *P. perlata* assumes its own next oldest name, *P. lepida*. Monotypic.

Distribution. Brazil from W Pará and E Amazonas S to CW Mato Grosso, and into N Bolivia.

Descriptive notes. 24 cm; 80-102 g. Head dark brown with buff flecking, bare orbital ring whitish, upper cheek green shading down to blue, ear-coverts flecked buff; sides of neck and upper breast scaled buff on grey; lower breast and belly red; flanks, thighs and vent blue; back and wings green with red shoulder and lesser underwing-coverts, blue in wing-coverts and violet blue in flight-feathers; tail brownish red, terminally blue, grey below. Immature replaces ventral red with green.

Habitat. Humid lowland forest, apparently preferring denser vegetation at forest edge and in secondary growth.

Food and Feeding. Fruits of *Trema micrantha* at forest margins, *Tetragastris altissima*, *Goupia glabra*, *Alchornea discolor*, *Vismea cayennensis*, *Coussapoa trinervis*, *Pourouma minor*, *Pseudolmedia laevis*, *Psidium*, *Cecropia*, *Ficus*, *Eugenia*, *Zanthoxylum*, *Euterpe* palm fruits and *Cecropia* catkins, and flowers and fruit of *Bertholletia excelsa* and *Dioclea glabra*.

Breeding. Jul-Nov in S of range, sometimes later. In captivity: 3-6 eggs; incubation lasting 25 days; and nestling period 7-8 weeks.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Earlier this century great flocks were seen in S of range, and it seems likely that its overall status has changed little, despite increasing loss of habitat in the N. Common along Rio Jiparaná, Rondônia.

Bibliography. Anon. (1993), Arndt (1983), Arndt & Roth (1986), Bates *et al.* (1989), Beissinger & Snyder (1992), Collar (1997), Dubs (1992), Forrester (1993), van Hoek & King (1997), Low (1972), Naumburg (1930), Novaes (1976), Olrog (1968), Parker *et al.* (1991), Pinto (1964), Remsen & Traylor (1989), Ridgely (1981), Roth (1984a, 1984b), Sick (1985, 1993), Stotz *et al.* (1996), Wheatley (1994), Whitney (1996).

233. Pearly Parakeet

Pyrrhura lepida

French: Conure perlée **German:** Blausteißittich **Spanish:** Cotorra Pulcra
Other common names: Pearly Conure

Taxonomy. *Sittace lepida* Wagler, 1832, Amazonian Brazil.

Forms a parapatric species pair with *P. perlata*, with which sometimes considered conspecific. Confused taxonomic history: present species until recently known as *P. perlata*, but as that name is actually applicable to the form long known as *P. rhodogaster*, present species consequently assumes its next oldest name, *P. lepida*. Three subspecies recognized.

Subspecies and Distribution.

P. l. lepida (Wagler, 1832) - NC Brazil, in NE Pará and NW Maranhão.

P. l. anerythra Neumann, 1927 - NC Brazil, in E Pará.

P. l. coerulescens Neumann, 1927 - NC Brazil, in W & C Maranhão.

Descriptive notes. 24 cm; 70-80 g. Head dark brown, slightly mottled buff on nape, bare orbital ring whitish, cheeks dull blue-green, ear-coverts buff; upper breast and sides of neck scaled buff on mid-brown, with some blue suffusion on mid-breast; remaining underparts green with blue suffusion on flanks and thighs; upperparts as *P. perlata*. Immature similar. Race *coerulescens* has paler head, upper breast with stronger blue tinge; *anerythra* lacks blue breast tinge and red in wing, but has red tinge to lower breast and belly.

Habitat. Humid *terra firme* forest, forest edge and secondary growth, sometimes ranging into adjacent clearings.

Food and Feeding. No information, other than vegetable material found in a stomach.

Breeding. No information; a female was in 100% moult in Sept.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Range similar to that of *Guarouba guarouba*, so habitat loss has been very serious for this species too, but it occurs at higher densities than *G. guarouba*, is more tolerant of disturbed habitats, and suffers little persecution for trade. Nonetheless, the race *coerulescens* appears to have suffered almost total clearance of habitat and may be approaching extinction, and the other races may also be in increasing difficulties.

Bibliography. Anon. (1993), Arndt & Roth (1986), Clausen (1986), Collar & Andrew (1988), Forrester (1993), Low (1972), Novaes (1969), Olrog (1968), Pinto (1964), Ridgely (1981), Ruschi (1979), Sick (1985, 1993), Stotz *et al.* (1996), Wheatley (1994), Whitney (1996).

234. Green-cheeked Parakeet

Pyrrhura molinae

French: Conure de Molina **German:** Molinasittich **Spanish:** Cotorra de Molina
Other common names: Green-cheeked Conure

Taxonomy. *Conurus molinae* Massena and Souancé, 1854, Bolivia.

Some of listed subspecific variation may be clinal, given size of range and absence of disjunction. Population in valley of R Machariapo, Bolivia, lacking red belly patch, may be a separate race unless flocks of immatures form. Population of W Brazil formerly known as "*P. hypoxantha*" (Yellow-sided Parakeet), but now judged to be xanthistic birds of nominate race. Five subspecies recognized.

Subspecies and Distribution.

P. m. phoenicura (Schlegel, 1864) - NE Bolivia and W Brazil.

P. m. molinae (Massena & Souancé, 1854) - highland E Bolivia.

P. m. restricta Todd, 1947 - lowland E Bolivia.

P. m. sordida Todd, 1947 - extreme E Bolivia and SW Brazil.

P. m. australis Todd, 1915 - S Bolivia to NW Argentina.

Descriptive notes. 26 cm; 62-81 g. Forehead to nape dull brown; bare orbital ring creamy white; cheeks green; ear-coverts ashy brown; chin, throat and sides of neck scaled brown and whitish, brown and yellow on breast; rest of body green except dull reddish belly, bluish flight-feathers, dull reddish tail. Immature lacks belly patch. Race *phoenicura* has upper tail green basally; *restricta* has blue tinge to cheeks and blue collar, reduced belly patch; *sordida* has less distinct scaling on breast, paler crown; *australis* generally paler, more extensive belly patch.

Habitat. Deciduous lowland woodland, secondary forest, gallery woodland in Pantanal and humid subtropical forest up to 2000 m or more.

Food and Feeding. No information.

Breeding. Feb in Argentina. Nest in hole in tree, in one case 5 m from ground. Eggs 3; in captivity, incubation lasts 22-24 days, with a nestling period of 7 weeks.

Movements. Higher altitude populations descend in autumn and winter, i.e. presumably Mar-Aug. **Status and Conservation.** Not globally threatened. CITES II. Occurrence in N Paraguay still not proven. Common in much of range, and with much habitat remaining. Not widely traded, with only 1345 exported from Argentina in the years 1985-1990 and no quota authorised for 1993.

Bibliography. Babarskas *et al.* (1995), Canevari *et al.* (1991), Collar & Andrew (1988), Darrieu (1980a), Fjeldsø & Krabbe (1990), Harris, F. & Harris (1982), Harris, R. (1994b), Hayes (1995), Hoy (1968), Inskip *et al.* (1988), Low (1972), Merck (1984), Niethammer (1953), Nores & Yzurieta (1994), Orfila (1937), Pearman (1993), de la Peña (1988), Pinto (1964), Remsen & Traylor (1989), Ridgely (1981), Short (1975), Sick (1985, 1993), Smith (1979b), Stotz *et al.* (1996), Whitney (1996), Würth (1997a).

235. Painted Parakeet

Pyrrhura picta

French: Conure versicolore **German:** Rotzügelsittich **Spanish:** Cotorra Pintada

Other common names: Painted Conure

Taxonomy. *Psittacus pictus* P. L. S. Müller, 1776, Cayenne.

Superspecific relations unclear, with strongest relations to *P. leucotis* and *P. melanura*. Some interest in establishing disjunct forms in NW of range as full species, but variation is as great within apparently contiguous "Amazonian" populations; nevertheless, race *eisenmanni* may be closer to *P. leucotis* than to present species, and *eisenmanni* and *caeruleiceps* appear closer to each other than either is to others in the *P. picta*-*P. leucotis* complex. Nine subspecies recognized.

Subspecies and Distribution.

P. p. eisenmanni Delgado, 1985 - Azuero Peninsula, Panama.

P. p. subandina Todd, 1917 - NW Colombia in Sinú Valley.

P. p. caeruleiceps Todd, 1947 - N Colombia on W slope of E Andes.

P. p. pantchenkoi Phelps, 1977 - Colombia-Venezuela border in Sierra de Perijá.

P. p. picta (P. L. S. Müller, 1776) - Venezuela through the Guianas to N Brazil (Amapá).

P. p. amazonum Hellmayr, 1906 - NC Brazil, in Pará N of Amazon.

P. p. microtera Todd, 1947 - NC Brazil S of Amazon from Pará to Tocantins.

P. p. lucianii (Deville, 1851) - NW Brazil, SE Ecuador, NE Peru and along rivers in N Bolivia.

P. p. roseifrons (G. R. Gray, 1859) - W Brazil and E Peru, S and E of previous race.

Descriptive notes. 22 cm; 46-85 g. Forehead to mid-crown blue shading to deep maroon on hindcrown and nape bounded by narrow blue collar; face maroon; bare orbital skin greyish; ear-coverts whitish; sides of neck and breast buff with reddish brown centres to feathers, producing marked scalloped effect; remaining underparts green with dull red belly patch; upperparts green with dull red lower back and rump, red carpal, blue in primaries; tail green basally, maroon distally. Immature lacks red carpal and has whitish orbital ring. Races vary considerably in distribution of colours, with *roseifrons* possessing orange-red head and face

with yellow ear-coverts.

Habitat. Humid *terra firme* forest and edge, seasonally flooded (*várzea*) forest, also coastal sand-ridge and savanna forests, cloud forest in foothills and lower slopes in W Andes, ranging out into partly cleared areas; generally 100-1300 m, with *pantchenkoi* reaching 2000 m. Tends to occupy canopy or lower stages of forest interior more than disturbed edges and second growth.

Food and Feeding. Fruits of *Goupia glabra*, *Bagassa guianensis*, *Trema micrantha*, *Heisteria spruceana*, *Zanthoxylum rhoifolium*, *Cordia*, *Protium*, *Alchornea*, *Drypetes*, *Mimosa*, *Byrsonima*, *Dicella*, *Heteropteris*, *Cecropia*, *Ficus*, *Psidium*, *Pourouma*, *Eugenia* and *Euterpe*, flowers and fruit of *Cochlospermum orinocense* and *Symphonia globulifera*, *Allantoma lineata*, *Bertholletia excelsa*, *Dioclea glabra*, flowers of *Erythrina amazonica*, seeds of *Cecropia miparia* and algae from the surface of deep pools.

Breeding. Jan-Mar in Panama; Mar-Jun in Colombia; Dec-Feb in the Guianas; Jun-Sept in S of range. Nest a hole in a tree. Normally 4-5 eggs in captivity.

Movements. No evidence of any displacements.

Status and Conservation. Not globally threatened. CITES II. Common in flocks inside forest, Guianas. Present in Manu National Park, Peru, where density reaches 4 pairs/km². Races *pantchenkoi* and *eisenmanni* under some stress from habitat loss, and *subandina* possibly now extremely rare for same reason. No serious threat from trade, despite great attractiveness of all races.

Bibliography. Bond & Meyer de Schauensee (1943), Delgado (1985a, 1985b), Desenne (1994), Desenne & Strahl (1991, 1994), Haverschmidt & Mees (1994), Hilty & Brown (1986), Low (1972), Meyer de Schauensee & Phelps (1978), Müller & Neumann (1997), O'Neill (1981), Pinto (1964), Ridgely (1981), Ridgely & Gwynne (1989), Roth (1984a), Schubart *et al.* (1965), Sick (1985, 1993), Smith, G.A. (1982), Snyder (1966), Stotz *et al.* (1996), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Tostain *et al.* (1992), Whitney (1996).

236. Maroon-faced Parakeet

Pyrrhura leucotis

French: Conure emma **German:** Weißohrsittich **Spanish:** Cotorra Caripada
Other common names: Maroon-faced Conure, White-eared Parakeet/Conure

Taxonomy. *Psittacus leucotis* Kuhl, 1820, Brazil.

Claimed to form a superspecies with closely related *P. picta*, but interposing ranges unusual in such an arrangement. Proposed race (or even species) "*hypoxantha*" probably based on aberrant specimens of *P. molinae*. Five subspecies recognized.

Subspecies and Distribution.

P. l. emma Salvadori, 1891 - NW Venezuela.

P. l. auricularis Zimmer & Phelps, 1949 - NE Venezuela.

P. l. pfrimeri Miranda-Ribeiro, 1920 - C Brazil in Goiás.

P. l. griseipectus Salvadori, 1900 - NE Brazil.

P. l. leucotis (Kuhl, 1820) - E Brazil from Bahia to São Paulo.

Descriptive notes. 23 cm. Crown light brown, bluish on forehead and hindneck; face maroon with whitish ear-coverts; chin, throat, sides of neck and breast green with light buff scaling; underparts green with brownish red patch on belly; upperparts green with brownish red patch from lower back to tail-coverts; carpal area red; primaries with blue; tail brownish red above, duller below. Immature similar. Race *griseipectus* lacks bluish on forehead and replaces green of sides of neck and breast with grey; *pfrimeri* like latter but forehead and ear-coverts chestnut, crown and nape dull blue; *emma* like *leucotis* but blue on hindneck more

extensive, broader buff scaling on breast; *auricularis* similar but larger white ear-coverts.

Habitat. Tropical evergreen and deciduous forest edge, and adjacent clearings with scattered trees and groves, ranging to c. 600 m in Brazil but to 1700 m in Venezuela.

Food and Feeding. Reported to take seeds, fruits, berries, nuts and perhaps insects.

Breeding. No information from the wild. In captivity: 5-9 eggs; incubation, by female only, lasting 27 days; nestling period around 5 weeks.

Movements. Some dispersive movements may occur to and from deciduous habitats, resulting in occasional vagrant records in N Venezuela.

Status and Conservation. Not globally threatened, CITES II. Locally fairly common to abundant in Venezuela, although *auricularis* is suffering from habitat loss. All Brazilian races are under considerable pressure: *pfrimeri* and *griseipectus* are confined to very small areas of unprotected habitat, the latter in the biologically important Serra de Baturité, Ceará, while nominate *leucotis* occupies virtually the same few forest remnants as *P. cruentata*, although extending marginally further S. Trade virtually or actually non-existent.

Bibliography. Brook (1907), Desenne & Strahl (1991, 1994), Forrester (1993), Galetti & Stotz (1996), Harrison & Holyoak (1970), Lever (1987), Low (1972), Meyer de Schauensee & Phelps (1978), Pinto (1964), Restall (1970), Ridgely (1981), Schubart *et al.* (1965), Schubart *et al.* (1965), Sick (1985, 1993), Smith, G.A. (1982), Stotz *et al.* (1996), Vriends (1979), Whitney (1996), Willis (1992).

237. Santa Marta Parakeet

Pyrrhura viridicata

French: Conure des Santa Marta **German:** Santa-Marta-Sittich **Spanish:** Cotorra de Santa Marta
Other common names: Santa Marta Conure

Taxonomy. *Pyrrhura viridicata* Todd, 1913, San Lorenzo, Santa Marta, Colombia. Monotypic.

Distribution. N Colombia in Sierra Nevada de Santa Marta.

Descriptive notes. 25 cm. Generally green, with red frontal band, white bare orbital ring, maroon ear-coverts and flecks on hindneck, broad red band across belly, reddish orange shoulder and primary coverts, blue in primaries and reddish brown on underside of tail. Immature undescribed.

Habitat. Humid montane forest, borders and adjacent clearings, 1800-2800 m.

Food and Feeding. No information.

Breeding. Possibly extended, with evidence for Jun-Nov. Nest in hole in stub. No further information.

Movements. Some seasonal movements occur

within known elevational range.

Status and Conservation. **VULNERABLE.** CITES II. A BirdLife “restricted-range” species. Although judged or assumed throughout 1980’s to be relatively common and secure within the Sierra Nevada de Santa Marta National Park, and with no trade recorded, recent fieldwork has shown that only 15% of the massif’s original habitat remains, with extensive clearance for marijuana growth

compounded by damage caused by herbicides dropped on the marijuana. Within the altitude of the species only 200 km² of habitat remains, and no more than 5000 birds can now survive.

Bibliography. Collar (1996), Collar *et al.* (1994), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Low (1972), Olrog (1968), Ridgely (1981), Stotz *et al.* (1996), Todd & Carriker (1922), Wege & Long (1995), Wheatley (1994), Whitney (1996).

238. Fiery-shouldered Parakeet

Pyrrhura egregia

French: Conure aile-de-feu **German:** Feuerbugsittich **Spanish:** Cotorra Egregia
Other common names: Fiery-shouldered Conure

Taxonomy. *Conurus egregius* P. L. Sclater, 1881, “supposed to be from Demerara”. Two subspecies recognized.

Subspecies and Distribution.

P. e. egregia (P. L. Sclater, 1881) - SE Venezuela and adjacent SW Guyana.

P. e. obscura Zimmer & Phelps, 1946 - S Venezuela and adjacent extreme NE Brazil.

Descriptive notes. 25 cm. Generally green; crown and lores brown edged green; ear-coverts reddish brown; sides of neck and breast edged whitish and tipped dark, giving light scaled effect; belly with variable reddish brown patch; bend of wing, carpal edge and lesser underwing-coverts yellow marked orange; flight-feathers with blue; tail above dark reddish brown basally green, grey below. Immature has green crown, less colour in wing. Race *obscura* darker.

Habitat. Tepuí (tabletop) forest and edge, ranging round the bases of these mountains, 700-1800 m.

Food and Feeding. No information.

Breeding. No information.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. A BirdLife “restricted-range” species. Apparently common, but there is considerable loss of habitat in the range of nominate *egregia* in Venezuela, but not of *obscura*; much of this range in supposedly inside Gran Sabana National Park. Trade is actually or virtually non-existent.

Bibliography. Desenne & Strahl (1991, 1994), Forrester (1993), Low (1972, 1994c), Mayr & Phelps (1967), Meyer de Schauensee & Phelps (1978), Olrog (1968), Pinto (1964, 1966), Ridgely (1981), Sick (1985, 1993), Snyder (1966), Stotz *et al.* (1996), Wheatley (1994), Whitney (1996).

239. Maroon-tailed Parakeet

Pyrrhura melanura

French: Conure de Souancé **German:** Braunschwanzsittich **Spanish:** Cotorra Colinegra
Other common names: Maroon-tailed Conure

Taxonomy. *Aratinga melanurus* Spix, 1824, Tabatinga, Rio Solimões, Brazil. Forms a superspecies with *P. orcesi*, but also pairs parapatrically with *P. picta*. Races *pacifica* and *chapmani* are particularly distinctive forms, but the variability in *berlepschi* and *souancei* may overlap, requiring the two to be merged. Five subspecies recognized.

Subspecies and Distribution.

P. m. pacifica Chapman, 1915 - SW Colombia and NW Ecuador.
P. m. chapmani Bond & Meyer de Schauensee, 1940 - E slope of C Andes of Colombia at 1600-2800 m.
P. m. melanura (Spix, 1824) - S Venezuela through NW Brazil to SE Colombia, E Ecuador and NE Peru.
P. m. souancei (J. Verreaux, 1858) - SC Colombia near Macarena Mts.
P. m. berlepschi Salvadori, 1891 - E slope of Andes in SE Ecuador and N Peru.

Descriptive notes. 24-25 cm; 83 g. Generally green; frontal band dark reddish brown; crown and nape brown edged green, bare orbital ring white; throat, sides of neck and breast dark green edged buffy whitish, giving scaled effect; primary coverts red, tipped yellowish orange; outer primaries blue, with narrow green fringe on outer web; tail deep maroon above, green at base, dusky greyish below. Immatures similar to adult. Race *souancei* has more strongly scaled throat, all-red primary coverts, sometimes red on carpals, brownish red belly, and blacker undertail; *berlepschi* has still stronger throat scaling, carpal and belly markings invariably present; *pacifica* lacks white orbital ring and has green forecrown; *chapmani* larger, with breast scaling extending round hindneck, crown more solid brown, less red in wing, and red belly patch.

Habitat. Cloud forest, lowland wet forest in premontane zones, seasonally flooded (*várzea*) forest, borders and partially cleared areas. Generally only to 500 m, though sometimes higher.

Food and Feeding. Poorly documented. Fruits of *Miconia theaezans* and other Melastomataceae recorded, also of *Fagra (Zanthoxylum) tachuelo*, and seeds found in stomachs.

Breeding. Copulation seen in Jan, Colombia; Apr-Jun, E Ecuador. In captivity: 4 eggs; incubation lasting c. 25 days; nestling period 7-8 weeks.

Movements. Seasonal movements have been speculated to account for gaps in records at some sites in Colombia.

Status and Conservation. Not globally threatened. CITES II. Generally fairly common, and in places in S Colombia the most numerous parrot; however, race *pacifica* relatively uncommon. Minimal habitat loss or trade pressure in Venezuela, and indeed virtually no trade anywhere in range.

Bibliography. Davis (1986), Desenne & Strahl (1991, 1994), Dugand & Borrero (1948), Fjeldså & Krabbe (1990), Friedmann (1948b), Hilty & Brown (1986), Inskipp *et al.* (1988), Lehmann (1957), Lemke (1977), Low (1972), Meyer de Schauensee & Phelps (1978), O'Neill (1981), Pearson (1972), Phelps & Phelps (1958), Pinto (1964), Rhodes (1970), Ridgely (1981), Ridgely & Gaulin (1980), Ridgely & Robbins (1988), Sick (1985, 1993), Spenkelink-van Schaik (1980c), Stotz *et al.* (1996), Whitney (1996).

240. El Oro Parakeet

Pyrrhura orcesi

French: Conure d'Orcès **German:** Orcessittich **Spanish:** Cotorra de El Oro
Other common names: El Oro Conure

Taxonomy. *Pyrrhura orcesi* Ridgely and Robbins, 1988, c. 9-5 road km west of Piñas, c. 900 m, 3°40' S, 79°44' W, Province of El Oro, Ecuador. Forms a superspecies with *P. melanura*. Monotypic.

Distribution. SW Ecuador.

Descriptive notes. 22 cm; 65-75 g. Close to *P. melanura* but lores and forehead red, scaled pattern of breast and sides of neck reduced to broad but indistinct greyish buff bars on green, belly variably marked dull reddish, bend of wing red, more blue in primaries, tail green basally, and undertail appears redder (tone similar in *P. melanura chapmani*). Female has red on head reduced to narrow band on forehead. Immature has less red on head and bend of wing, no belly mark.

Habitat. Very humid upper tropical forest, 300-1300 m.

Food and Feeding. Fruits of fig *Ficus* cf. *macbridei*, tiliacean *Heliocarpus popayanensis*, euphorb *Hieronyma*, *Cecropia* and berries.

Breeding. Fledged young being fed Jun and Aug, so breeding may extend from Mar to Jul.

Movements. No information.

Status and Conservation. **VULNERABLE.** CITES II. A BirdLife "restricted-range" species. Population estimated to lie between 2000 and 20,000 birds, under pressure from continuing habitat clearance for ranchland. No protected area holds a population of this bird; the type locality at Hacienda Buenaventura possesses some 1000 ha of forest whose formal protection is still being negotiated.

Bibliography. Beissinger & Snyder (1992), Best & Clarke (1991), Best & Kessler (1995), Best, Checker *et al.* (1996), Best, Clarke *et al.* (1993), Bloch *et al.* (1991), Collar (1996), Collar, Crosby & Stattersfield (1994), Collar,

Gonzaga *et al.* (1992), Ortiz & Carrión (1991), Ridgely & Robbins (1988), Shuker (1993), Stotz *et al.* (1996), Vuilleumier *et al.* (1992), Wege & Long (1995), Wheatley (1994), Whitney (1996), Williams & Tobias (1994).

241. Black-capped Parakeet

Pyrrhura rupicola

French: Conure à cape noire **German:** Schwarzkappensittich **Spanish:** Cotorra Capirotada
Other common names: Black-capped Conure, Rock Parakeet/Conure

Taxonomy. *Conurus rupicola* Tschudi, 1844, Peru.

An apparent hybrid of present species with *P. molinae* has been taken in SE Peru, indicating these forms possibly conspecific, but substantial differences remain. Both describers of race *sandiae* were evidently sceptical of its distinctness. Two subspecies tentatively recognized.

Subspecies and Distribution.

P. r. rupicola (Tschudi, 1844) - C Peru.
P. r. sandiae Bond & Meyer de Schauensee, 1944 - SE Peru, extreme W Brazil and N Bolivia.

Descriptive notes. 25 cm; 75 g. Forehead to nape dusky brown, with whitish edges to hindneck; bare orbital ring white, face and ear-coverts green; sides of neck, throat and breast buff-white with dark brown centres to feathers, producing marked scalloped effect; rest of body green but carpals and primary coverts red, primaries with slight blue tinge, underside of tail greyish brown. Immature lacks red in wing. Race *sandiae* has narrower scalloping.

Habitat. Humid lowland *terra firme* and seasonally flooded *várzea* forest and edge, ranging into foothills of Andes.

Food and Feeding. No information.

Breeding. Copulation seen in Sept. In captivity up to 7 eggs.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Fairly common, with much still pristine habitat within range and apparently no trade pressure, so numbers presumed stable; it is common in Manu National Park, where density reaches 3-5 pairs/km².

Bibliography. Allen (1995), Bond (1955), Glogowsky (1994), Low (1972), O'Neill (1974, 1981), Olog (1968), Parker *et al.* (1982), Pinto (1964), Remsen & Traylor (1989), Ridgely (1981), Sick (1979c, 1985, 1993), Stotz *et al.* (1996), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Wheatley (1994), Whitney (1996).

242. White-necked Parakeet

Pyrrhura albipectus

French: Conure à col blanc **German:** Weißhalsstittich **Spanish:** Cotorra Cuelliblanca
Other common names: White-necked Conure, White-breasted Parakeet/Conure

Taxonomy. *Pyrrhura albipectus* Chapman, 1914, Zamora, 3000 feet (c. 1000 m), Loja, Ecuador. Possible hybrids with *P. melanura berlepschi* in Cordillera de Cutucú suggest present species may eventually be regarded as a race of *P. melanura*. Monotypic.

Distribution. SE Ecuador.

Descriptive notes. 24 cm; 83-110 g. Very thin dark reddish brown frontal band, with forehead to hindcrown brownish edged grey, more so towards rear, and white bare orbital ring; cheeks green with yellow scaling, and orange auricular spot; full broad white collar; yellow breast, rusty tone on belly; rest green with primary coverts red, primaries deep bluish; distal half of uppertail dull reddish; undertail dusky with rufescent tipping in fresh plumage. Immature lacks frontal band and has paler auricular spot, white breast.

Habitat. Primary upper tropical and subtropical forest, edge and clearings at 900-2000 m.

Food and Feeding. Fruits of *Tetrorchidium macrophyllum*, *Alchornea glandulosa*, *Miconia* cf. *punctata*, *Ficus* aff. *mutisii*, seeds of *Mollia grandis* and flowers of the vines *Mikania leiostachya* and *Piptocarpha* cf. *poepigiana*, the latter taken low in vegetation.

Breeding. May-Jul. No further information.

Movements. No information.

Status and Conservation. **VULNERABLE.** CITES II. A BirdLife "restricted-range" species. The species appears to be uncommon, and the total population may only be a few thousand birds. Forests at the species's elevation are under great pressure, and even Podocarpus National Park, one of the four sites known for the species, has a chequered history of mining concession agreements and local clearance; the Cordillera de Cutucú, another site, is a Shuar Indian reserve, but to claim land the Shuars have to clear at least part of it. The species may, however, be found in N Peru and prove rather more secure than it appears at present. Minor local trade may exist.

Bibliography. 243. Brown-breasted Parakeet

Pyrrhura calliptera

French: Conure à poitrine brune **German:** Braunbrustsittich **Spanish:** Cotorra Pechiparda
Other common names: Flame-winged/Brown-backed Parakeet/Conure, Brown-breasted Conure

Taxonomy. *Conurus callipterus* Massena and Souancé, 1854, Colombia.
Monotypic.

Distribution. E Andes of Colombia.

Descriptive notes. 22-23 cm. Crown and nape brown with green fringing; face green with dusky markings, bare orbital ring white; ear-coverts deep reddish brown; breast and sides of neck mid-brown lightly barred buff; underparts green with reddish brown on belly; upperparts green with carpal edge and primary coverts yellow often with some orange, primaries blue; tail reddish brown. Immature lacks yellow in wing.

Habitat. Cloud forest edge, elfin woodland, second growth and shrubbery with interspersed areas of subpáramo, peatbog páramo and man-made clearings, 1700–3400 m.

Food and Feeding. Blueberries, blackberries *Rubus*, fruit of *Clusia*, *Ficus* and *Brunellia colombiana*, seeds of *Espeletia uribei* and *Cecropia*, and cultivated maize.

Breeding. Aug-Oct. No further information.

Movements. No information.

Status and Conservation. VULNERABLE. CITES II. A BirdLife “restricted-range” species. Apparently extinct on the entire W slope of the E Andes (no records since 1913, when it was common) owing to habitat loss, with a steep decline throughout Cundinamarca, although much habitat still remains in Boyacá. No international trade and only light pressure for local trade; birds are persecuted to defend maize crops, and this problem will intensify with further deforestation for farming. Present in Chingaza National Park and adjacent protected areas (Río Blanco Forest Reserve, Carpanta Biological Reserve).

Bibliography. Beissinger & Snyder (1992), Chapman (1917), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Low (1972), Olivares (1969, 1971), Olog (1968), Orejuela (1985), Ridgely (1981), Rodríguez & Hernández (1988), Stotz *et al.* (1996), Wege & Long (1995), Whitney (1996).

244. Red-eared Parakeet

Pyrrhura hoematotis

French: Conure à oreillons **German:** Blutohrsittich **Spanish:** Cotorra Colirroja
Other common names: Red-breasted/Blood-eared Parakeet/Conure, Red-eared Conure

Taxonomy. *Pyrrhura hoematotis* Souancé, 1857, Venezuela.
Two subspecies recognized.

Subspecies and Distribution.

P. h. immarginata Zimmer & Phelps, 1944 - NW Venezuela.

P. h. hoematotis Souancé, 1857 - N Venezuela.

Descriptive notes. 25 cm; 64-74 g. Generally green; forehead to mid-crown slaty, bare orbital ring white; ear-coverts bright terracotta; nape edged yellow; sides of neck greyish finely edged white; throat and upper breast lightly scaled greyish; belly with variable reddish brown; undertail-coverts bluish green; primaries with blue; tail brownish red, extreme tips green, coppery below. Immature undescribed. Race *immarginata* lacks pattern on side of neck, dark crown and yellow edges to nape.

Habitat. Cloud forest, savanna woodland, edges and clearings with scattered trees in coastal mountains, mostly at 1000-2000 m,

entering semi-deciduous forest at lower levels in the dry season.

Food and Feeding. Little information. Fruit, including cultivated *Psidium guajava*, blossoms, and the petioles of certain broad leaves, possibly for insect larvae.

Breeding. Aug (wet season). No further information.

Movements. Dry season movements occur to lower levels.

Status and Conservation. Not globally threatened. CITES II. A BirdLife “restricted-range” species. Common within its small range, especially in Henri Pittier National Park, with flocks of over 100 frequent. However, there is steady loss of habitat, especially at the only locality known for race *immarginata*. Little sought after in trade.

Bibliography. Beebe (1947), Desenne & Strahl (1991, 1994), Fernández-Badillo *et al.* (1994), Low (1972), Meyer de Schauensee & Phelps (1978), Ridgely (1981), Schäfer & Phelps (1954), Stotz *et al.* (1996), Wheatley (1994), Whitney (1996), Zimmer & Phelps (1944).

245. Rose-headed Parakeet

Pyrrhura rholocephala

French: Conure tête-de-feu **German:** Rotkopfsittich **Spanish:** Cotorra Coronirroja
Other common names: Rose-headed Conure, Rose-crowned Parakeet/Conure

Taxonomy. *Conurus rholocephalus* P. L. Sclater and Salvin, 1871, vicinity of Mérida, Venezuela.
Monotypic.

Distribution. W Venezuela.

Descriptive notes. 24-25 cm. Forehead to nape red, ear-coverts light maroon; bare orbital ring white; face and sides of neck green, shading to vaguely brown-barred green on underparts; upperparts green with yellow carpal edge, white primary coverts and blue in primaries; tail reddish brown, dusky below. Immature lacks red in crown.

report of serious decline appears to be based on misreading. Little trade recorded.

Bibliography. Arndt (1988), Collar *et al.* (1994), Desenne & Strahl (1991, 1994), Fjeldså & Krabbe (1990), Low (1972), Meyer de Schauensee & Phelps (1978), Olog (1968), Ridgely (1981), Stotz *et al.* (1996), Wheatley (1994), Whitney (1996).

246. Sulphur-winged Parakeet

Pyrrhura hoffmanni

French: Conure de Hoffmann **German:** Hoffmannsittich **Spanish:** Cotorra Catana
Other common names: Hoffmann's Parakeet/Conure, Sulphur-winged Conure

Taxonomy. *Conurus hoffmanni* Cabanis, 1861, Costa Rica.
Two subspecies recognized.

Subspecies and Distribution.

P. h. hoffmanni (Cabanis, 1861) - Costa Rica.

P. h. gaudens Bangs, 1906 - W Panama.

Descriptive notes. 23-24 cm; mean 82 g. Generally green; head, nape and throat variably marked with yellow, breast with dull orange; bare orbital ring white; ear-coverts bright terracotta; primary coverts and basal two-thirds of inner primaries and outer secondaries yellow; primaries with blue; tail rufous olive above fringed green, reddish brown below. Immature has duller scaling, less orange, and much less yellow on wing. Race *gaudens* has head with variable orange red markings, underparts slightly darker.

Habitat. Broken mountainous country in primary and logged forest and edge, adjacent shrubbery and second growth, with an apparent preference for partly cleared pasture; 700-3000 m.

Food and Feeding. Seeds, fruits of *Ficus*, *Croton*, *Myrtis*, *Miconia* and *Leandra subseriata*, sometimes making daily elevational movements from upper roosting areas.

Breeding. Probably mainly Jan-Jun. Nest in old woodpecker hole or hollow broken stub, 8-20 m up. In captivity: 6 eggs; incubation 24 days; nestling period 10 weeks.

Movements. In dry season regularly present up to 3000 m, descending in wet season to 1300 or even 700 m at least on daily visits; once near sea-level.

Status and Conservation. Not globally threatened. CITES II. A BirdLife “restricted-range” species. Fairly common to common within its small range, and tolerant of substantial habitat modification. Very little trade.

Bibliography. Anon. (1983), Blake (1958), Hernández-Baños *et al.* (1995), Leck & Hilty (1968), Low (1972), Orians (1969), Ridgely (1981), Ridgely & Gwynne (1989), Rowley (1985), Slud (1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Taylor, K. (1993), Wetmore (1968), Whitney (1996), Wolf (1976).

Genus ENICOGNATHUS G. R. Gray, 1840

247. Austral Parakeet

Enicognathus ferrugineus

French: Conure magellanique **German:** Smaragdsittich **Spanish:** Cotorra Cachaña
Other common names: Austral Conure

Taxonomy. *Psittacus ferrugineus* P. L. S. Müller, 1776, Straits of Magellan.

Formerly placed in a separate monospecific genus, *Microsittace*. Racial differences may be clinal. Two subspecies currently recognized.

Subspecies and Distribution.

E. f. minor (Chapman, 1919) - S Chile and SW Argentina.

E. f. ferrugineus (P. L. S. Müller, 1776) - extreme S of both Chile and Argentina.

Descriptive notes. 28-36 cm. Dull green, yellower on underparts, with light scaled effect given by dark feather edging; forehead and lores, belly patch and tail dull reddish; primaries with bluish green. Immature has duller reddish on head and belly. Race *minor* smaller and darker.

Habitat. Southern temperate beech *Nothofagus* forest, *Quercus-Drymis* woodlands, and adjacent semi-open areas, including ranchland and at times cultivations; to sea-level in S of range, up to 1200 or even 2000 m in N.

Food and Feeding. Seeds of grasses and the bamboo *Chusquea quila*, seeds of *Araucaria araucana*, acorns, leaf buds of *Nothofagus* and poplars, fruits, berries and bulbous roots.

Breeding. Dec. Nest in hole in tree, commonly large dead oaks; reportedly also makes own nest of twigs or grass stems in *Chusquea*. Eggs 4-8; incubation in captivity timed at c. 26 days.

Movements. Resident in S of range, despite severity of winter; in N downslope movements in winter (Argentine birds ranging into Chile), extent and timing variable with year and thought related to weather and food availability.

Status and Conservation. Not globally threatened. CITES II. Common throughout range, with much suitable habitat inside protected areas in both Chile (e.g. Villarica National Park) and Argentina (e.g. Nahuel Huapi National Park). Very uncommon in captivity. Can cause damage to crops in lowlands in winter.

Bibliography. Araya & Chester (1993), Bernath (1965), Canevari *et al.* (1991), Clark (1986), Darrieu (1982), Fjeldsá & Krabbe (1990), Housse (1949), Humphrey *et al.* (1970), Ireland & McGee (1981), Johansen (1966), Johnson (1967), Low (1972), Nores & Yzurieta (1994), Olrog (1948, 1984), de la Peña (1988), Peters & Blake (1948), Ridgely (1981),

Spenkelink-van Schaik (1980b), Stotz *et al.* (1996), Vuilleumier (1985), Whitney (1996).

248. Slender-billed Parakeet

Enicognathus leptorhynchus

French: Conure à long bec **German:** Langschnabelsittich **Spanish:** Cotorra Choroy
Other common names: Slender-billed Conure

Taxonomy. *Psittacara leptorhyncha* King, 1831, Chiloé Island. Monotypic.

Distribution. C Chile.

Descriptive notes. 40 cm. Very similar to *E. ferrugineus* but larger and somewhat chunkier; lacks scaled effect on undersides, and has brighter, more extensive reddish on forehead; upper mandible greatly elongated. Immature darker green, skin around eye whitish.

Habitat. Southern temperate *Nothofagus* and *Araucaria* forests, ranging sometimes (notably in winter) into semi-open farming areas and pastures. Up to 2000 m in summer.

Food and Feeding. Buds, berries, grass and thistle seeds, but notably *Araucaria* seeds in autumn (Mar-Apr) and *Nothofagus* seeds at other times; feeds both in trees and on ground,

where uses bill to dig up bulbous roots. Can cause damage in crops and apple orchards.

Breeding. Nov-Dec. Nest in hole in tree (often several pairs in one tree), the birds dropping dry twigs into deep holes to raise the floor; occasionally rock crevices are used, and like *E. ferrugineus* birds are reported to construct twig nests in *Chusquea* bamboo if no apertures available. Eggs 2-6.

Movements. Elevational displacements occur in winter to lower levels, May-Sept.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. Decline in 1950's and 1960's owing to forest clearance, hunting and Newcastle disease, but still fairly common locally, and highly gregarious (up to 2000 in roosts at least formerly) throughout year; considered the most serious agricultural pest on Chiloé I.

Bibliography. Araya & Chester (1993), Fjeldsá & Krabbe (1990), Green (1993), Housse (1949), Johnson (1967), Low (1972), Olrog (1968), Olson (1995), Peters & Blake (1948), Ridgely (1981), Sick (1968), Silva (1980a), Stotz *et al.* (1996), Vuilleumier (1985), Wheatley (1994), Whitney (1996).

Genus MYIOPSITTA Bonaparte, 1854

249. Monk Parakeet

Myiopsitta monachus

French: Conure veuve **German:** Mönchsittich **Spanish:** Cotorra Argentina
Other common names: Quaker/Grey-breasted Parakeet

Taxonomy. *Psittacus monachus* Boddaert, 1783, Montevideo, Uruguay.

Forms superspecies with *M. luchsii*, with which commonly considered conspecific. Three subspecies recognized.

Subspecies and Distribution.

M. m. cotorra (Vieillot, 1818) - S Bolivia, Paraguay, S Brazil and NW Argentina.

M. m. monachus (Boddaert, 1783) - SE Brazil, Uruguay and NE Argentina.

M. m. calita (Jardine & Selby, 1830) - W Argentina.

Introduced to many areas, especially in North America and Europe.

Descriptive notes. 28-29 cm; 90-140 g. Forehead, lores, lower cheek and chin light grey; rest of head green, browner green on mantle and duller on wings, primaries and secondaries deep blue on outer webs; lower back, rump and upperwing-coverts yellowish green; tail green with blue staining along feather shafts; breast brownish broadly edged light grey, creating scaled effect; broad yellowish olive band across belly; lower belly, thighs and vent yellowish green. Immature has forehead tinged green. Race *calita* smaller, head darker grey; *cotorra* like previous race but brighter green, belly less yellowish.

Habitat. Dry semi-open lowlands, generally to 1000 m, in gallery forest, savanna woodland, dry *Acacia* scrubland, xerophytic thickets, palm groves, woodlots, ranchland and orchards, especially near human habitation, also city parks and wooded suburban areas.

Food and Feeding. Seeds of grasses, herbs and various trees, especially *Celtis tala* and palm nuts, with thistles very important in breeding season; also fruits, berries, leaf buds, blossoms and insects. Serious pest of maize, sorghum and other cereals, plus sunflowers, peaches, pears and citrus crops.

Breeding. Oct-Feb. Communal nester. Builds conspicuous enclosed nests of sticks cut with bill, commonly from spiny *Celtis* bushes; nests often with several chambers, and sometimes many; sometimes solitary, but usually occupied (throughout the year) by different pairs and non-breeding individuals; highest available site preferred, hence nests placed in the tops of trees, notably introduced eucalypts, but also on pylons and windmills. Eggs 1-11 (fledging success greatest with around 7 eggs); incubation 24 days; nestling period in captivity c. 6 weeks. Higher productivity noted in eucalypts than in native vegetation; productivity generally amongst highest in psittacids owing to relatively high clutch size.

Movements. Apparently sedentary except at the edges of its range, where presence may be seasonal.

Status and Conservation. Not globally threatened. CITES II. Common to abundant throughout its range, and has increased with the spread of settlements (now encroaching into the *pampas* where eucalypts are planted), so that often now regarded as a major pest. From 1985 to 1989, 82,442 birds were exported from Argentina, and the export quota in 1993 was 24,000, regarded as high. Steadily expanding range and numbers in North America and Europe, with some concern that it will become a serious crop pest.

Bibliography. Aramburú (1991, 1995, 1996), van Bael & Pruett-Jones (1996), Belton (1984), Bucher & Martin (1987), Bucher & Nores (1988), Bucher *et al.* (1991), Caccamise (1980), Caccamise & Weathers (1977), Canevari *et al.* (1991), Contreras *et al.* (1990), Conway (1965), Dahlem (1994), Darrieu (1980b, 1981), Eberhard (1996), Eisenraut (1935), Fallavena & Silva (1988), Fjeldsá & Krabbe (1990), Gore & Gepp (1978), Hayes (1995), Humphrey & Peterson (1978), Hyman & Pruett-Jones (1995), Klimaitis & Moschione (1987), Lever (1987), Low (1972), Marone *et al.* (1992), Martella & Bucher (1990, 1993), Martella *et al.* (1985), Martín (1989), Martín & Bucher (1993), Naumburg (1930), Navarro (1988), Navarro & Bucher (1990, 1992), Navarro, Martella & Bucher (1992, 1995), Navarro, Martín & Bucher (1992), Neidermyer & Hickey (1977), Nores & Yzurieta (1994), de la Peña (1988, 1996), Ridgely (1981), Short (1975), Sick (1985, 1993), Sol *et al.* (1997), Spano & Truffi (1986), Spreyer (1994), Steinbacher (1962), Stotz *et al.* (1996), Vriends (1979), Wetmore (1926), Whitney (1996).

250. Cliff Parakeet

Myiopsitta luchsii

French: Conure des rochers **German:** Luchssittich **Spanish:** Cotorra Boliviana

Taxonomy. *Bolborrhynchus Luchsii* Finsch, 1868, Bolivia.

Usually treated as conspecific with *M. monachus*, but perhaps more appropriately related as forming a superspecies, given marked morphological differences and cliff-nesting habit. Monotypic.

Distribution. C Bolivia.

Descriptive notes. 26-28 cm. Similar to *M. monachus* but grey of forehead whiter and extending to mid-crown, pale grey on breast lacks scaly effect of darker feather-centres, band across belly more yellowish; outer webs of primaries all blue. Immature undescribed.

Habitat. Xerophytic vegetation and adjacent cliff areas near water in intermontane valleys, at 1300-3000 m, the bird's range being largely coincident with *Ara rubrogenys*.

Food and Feeding. Seeds of various fruit (never the same as those taken by *A. rubrogenys*), including those of carapari cacti *Neocardenasia herzogiana* and *Acacia furcatispina*; also cultivated maize.

Breeding. Dec-Mar. Bulky nest constructed of twigs packed into crevices in cliffs; also apparently amongst leaves of cliff-hanging bromeliads. Nests are non-communal but often immediately adjacent. Eggs unknown.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II (under *M. monachus*). Rather common but localized; some young are taken for local trade. No serious persecution despite attacks on maize.

Bibliography. Bond & Meyer de Schauensee (1943), Fjeldsá (1987), Fjeldsá & Krabbe (1990), Lanning (1991b), Low (1972), Ridgely (1981), Short (1975), Stotz *et al.* (1996), Whitney (1996).

Genus PSILOPSIAGON Ridgway, 1912

251. Grey-hooded Parakeet

Psilopsiagon aymara

French: Toui aymara **German:** Aymarassittich **Spanish:** Catita Aimará
Other common names: Aymara/Sierra/Grey-headed Parakeet

Taxonomy. *Arara aymara* d'Orbigny, 1839, Quebrada de Palca, Tacna, Chile; error = *Sicasica*, south of La Paz, Bolivia.

Often placed in genus *Bolborrhynchus*; in past in genus *Amoropsittaca*. Monotypic.

Distribution. NC Bolivia to NW Argentina.

Descriptive notes. 18-20 cm; 45-62 g. Dark greyish brown head and nape; lower cheek, throat, breast and belly pale silvery grey, flanks yellowish green, vent and undertail-coverts bluish green; upperparts green, darker on wings and tail. Female slightly paler on crown, less silvery grey on breast. Immature has shorter tail.

Habitat. Arid to semi-humid montane scrub, often in dense shrubbery and commonly in agricultural land, generally at 1800-3000 m, although both higher and lower than this.

Food and Feeding. Seeding grass, herbs (e.g. *Viguera* and other composites) and berries on bushes.

Breeding. Nov and Jan, in Argentina. Nest in hole in bank, or deserted building; even in cactus, and in the only case recorded up to 5 pairs were using one plant. Eggs 4-6, and up to 12 in captivity, where incubation lasts c. 28 days and the nestling period is 6-7 weeks.

(1988), Remsen & Traylor (1989), Ridgely (1981), Salvador & Narosky (1984), Stotz *et al.* (1996), Wetmore (1926), Wheatley (1994), Whitney (1996).

252. Mountain Parakeet

Psilopsiagon aurifrons

French: Toui à bandeau jaune **German:** Zitronensittich **Spanish:** Catita Frentidorada
Other common names: Golden-fronted Parakeet

Taxonomy. *Psittacus* (*Lathamus*) *aurifrons* Lesson, 1830, New Zealand; error = Peru. Often placed in genus *Bolborhynchus*. Four subspecies recognized.

Subspecies and Distribution.

P. a. robertsi Carriker, 1933 - NW Peru.

P. a. aurifrons (Lesson, 1830) - C Peru.

P. a. margaritae (Berlioz & Dorst, 1956) - S Peru and CW Bolivia to N Chile and extreme NW Argentina.

P. a. rubrirostris (Burmeister, 1860) - NW Argentina to C Chile.

Descriptive notes. 16-19 cm; 45 g. Green above from crown to wings and tail, with outer webs of flight-feathers blue; area around bill to eye yellow, extending down throat to merge into greenish yellow underparts; cheeks emerald green. Female lacks yellow around bill, and yellow elsewhere less pronounced. Immature like female. Race *robertsi* lacks yellowish wash in underparts; *margaritae* has shorter tail, and both sexes like nominate female, but bill grey; *rubrirostris* has bluer green upperparts, bluish grey wash on forehead and underparts, and bill flesh pink in male but grey in female.

Habitat. Riparian thickets, wooded and shrubby places with fog vegetation, slopes with composite brush, thorny scrub, *puna* cacti, sometimes even *puna* grassland with scattered bushes; often in gardens, cultivations and even city parks. Nominative *aurifrons* generally occurs at 1000-2900 m, although both higher and lower, along the arid coastal plain; *margaritae* at 3000-4500 m; *rubrirostris* at c. 2500 m.

Food and Feeding. In *puna* zone, buds and seeds of *Lepidophyllum*, *Fabiana densa* and *Adesmia* and other leguminous scrub, taken on bushes and from ground.

Breeding. Feb-Mar in Argentina; Oct-Dec in N Chile. Nest in burrow in dry riverbank, steep cliff or canyon. Eggs 3-6, in captivity up to 7; incubation, by female, possibly 23 days; nestling period reportedly 8 weeks.

Movements. Altitudinal migrant, moving to lower levels in winter.

Status and Conservation. Not globally threatened. CITES II. Common to locally abundant, although race *robertsi* appears to remain virtually unknown. Trade is slight.

Bibliography. Araya & Chester (1993), Canevari *et al.* (1991), Dorst (1956), Fjeldså & Krabbe (1990), Hoppe (1997c), Housse (1949), Hughes (1970), Johnson (1967), Koepcke (1970), Lönnberg (1903), Low (1972), Nellar (1993), Nores & Yzurieta (1994), O'Neill (1981), Peña (1961), de la Peña (1988), Remsen & Traylor (1989), Ridgely (1981), Salvador & Narosky (1984), Spenkelink-van Schaik (1981), Stotz *et al.* (1996), Whitney (1996), Zimmer (1930).

Genus *BOLBORHYNCHUS* Bonaparte, 1857

253. Barred Parakeet

Bolborhynchus lineola

French: Toui catherine **German:** Katharinasittich **Spanish:** Catita Barrada

Taxonomy. *Psittacula lineola* Cassin, 1853, "National Bridge, Mexico" = Puente Nacional, Veracruz. Two subspecies recognized.

Subspecies and Distribution.

B. l. lineola (Cassin, 1853) - S Mexico to W Panama.

B. l. tigrinus (Souancé, 1856) - N & W Venezuela patchily S to C Peru.

Descriptive notes. 16-18 cm; 42-59 g. Green in various shades throughout, bluish on forecrown, more olive on back, yellower below, with deeper olive wing-coverts and bottle green black-tipped flight-feathers and tail; indistinct dark barring from mid-crown to flanks and rump, becoming spots on uppertail-coverts; several broad bars on wings; bend of wing black. Female has lighter barring. Immature paler, barring less distinct, more bluish tinge to head. Race *tigrinus* more strongly barred.

Habitat. Humid evergreen and pine-evergreen cloud-forest groves, second growth and clearings; *tigrinus* especially where landslides have opened land for bamboo; 600-2400 m in Central America, 1600-3300 m in Peru.

Movements. Some altitudinal variation with season, higher in summer.

Status and Conservation. Not globally threatened. CITES II. Fairly common throughout most of its range. Well adapted to life in long established and intensively managed farmland. Traded in moderate numbers in mid-1980's, smaller numbers recently, without apparent effect.

Bibliography. Babarskas *et al.* (1995), Beckett (1964), Canevari *et al.* (1991), Fjeldså & Krabbe (1990), Inskipp *et al.* (1988), Johnson (1967), Low (1972), Nellar (1993), Nores & Yzurieta (1994), Nores *et al.* (1983), Olrog (1968), Orfila (1938), de la Peña

Status and Conservation. Not globally threatened. CITES II. Uncommon to frequent throughout range, occurring in flocks up to 150, but still probably overlooked owing to silent behaviour and cryptic plumage when perched; locally abundant in Cordillera de Talamanca, Costa Rica, less so elsewhere in country; in Colombia perhaps most numerous in Santa Marta mountains.

Bibliography. Bloch *et al.* (1991), Byrd (1994), Desenne & Strahl (1994), Fjeldså & Krabbe (1990), Furssedonn (1992), Hilty & Brown (1986), Howell (1990), Howell & Webb (1995a), Low (1972), Martínez-Sánchez (1989), Meyer de Schauensee & Phelps (1978), Miller (1963), Monroe (1968), O'Neill (1981), Oxley (1978), Prante (1980), Prestwick (1954), Rasmussen *et al.* (1996), Ridgely (1981), Ridgely & Gwynne (1989), Slud (1964), Smith (1978a), Stiles & Skutch (1989), Stotz *et al.* (1996), Vriends (1979), Wetmore (1968), Whitney (1996).

254. Andean Parakeet

Bolborhynchus orbynesius

French: Toui d'Orbigny **German:** Andensittich **Spanish:** Catita Andina

Taxonomy. *Myiopsitta Orbynesia* Souancé, 1856, Yungas, Bolivia.

Appears to form a superspecies with *B. ferrugineifrons*. Formerly called *B. andicolus*, and in past regarded as a race of *Psilopsiagon aurifrons*. Monotypic.

Distribution. Highlands of Peru and NC Bolivia.

Descriptive notes. 16-17 cm; 48-50 g. Differs from *B. ferrugineifrons* only in being slightly smaller, and in replacing rufous around bill with yellow tinging to green. Female and immature have less or no yellow tinging. Immature has lighter bill.

Habitat. Semi-arid cloud-forest, *Polylepis* woodlands, bushy ravines in more open country, preferring vegetation with more complex botanical composition, mainly at 3000-4000 m, occasionally much higher (over 6000 m) and seasonally lower.

Food and Feeding. Seeds, fruits and berries, taken in bushes, bamboo, leguminous trees,

and on the ground.

Breeding. Claimed to be in a burrow in a steep bank.

Movements. Moves altitudinally down to montane valleys outside breeding season.

Status and Conservation. Not globally threatened. CITES II. Common locally, sometimes in large flocks, with over 300 recorded; population stable.

Bibliography. Dorst (1961), Fjeldså & Krabbe (1990), Inskipp *et al.* (1988), Koepcke (1970), Low (1972), Morrison (1948), O'Neill (1981), Olrog (1968), Parker *et al.* (1982), Peters & Griswold (1943), Remsen & Traylor (1989), Ridgely (1981), Roe & Rees (1979), Stotz *et al.* (1996), Wheatley (1994), Whitney (1996), Whitney *et al.* (1994).

255. Rufous-fronted Parakeet

Bolborhynchus ferrugineifrons

French: Toui à front roux **German:** Rotstirnsittich **Spanish:** Catita Frentirrufo

Taxonomy. *Protogeris* [sic] *ferrugineifrons* Lawrence, 1880, Bogotá, Colombia.

Appears to form a superspecies with *B. orbynesius*. Monotypic.

Distribution. Colombia in C Andes.

Descriptive notes. 18-19 cm. Rich, fairly dark green, paler on underparts and rump; area around bill rufous; bluish on outer webs of primaries. Immature undescribed.

Habitat. Semi-humid and humid montane scrub and elfin forest at the border with *paramo* and agricultural areas, 3200-4000 m.

Food and Feeding. Ground-feeder, particularly taking grass seeds, including possibly *Calamagrostis effusa*, seeds of frailejones, and flowers and achenes of *Espeletia hartwegiana*.

Breeding. Males with developed gonads in Jan. Nests reportedly found in rock cavities in cliff.

Movements. No information. Likely to wander a little outside breeding season, and has been encountered as low as 2835 m.

Status and Conservation. **ENDANGERED.** CITES II. A BirdLife "restricted-range" species. Habitat degradation, caused by firewood-gathering, grazing, burning and cultivation, continues within its very restricted range, and it generally lives at low density, such that the total population might only be 1000-2000 birds. However, in Sept 1993 over 100 birds were seen in 8 hours in Los Nevados National Park, the bird's last stronghold. Also found in Alto Quindío Acame Natural Reserve and Ucumari Regional Park.

256. Mexican Parrotlet

Forpus cyanopygius

French: Toui du Mexique **German:** Blaubürzel-Sperlingspapagei **Spanish:** Cotorrita Mexicana
Other common names: Blue-rumped Parrotlet

Taxonomy. *Psittacula cyanopygia* Souancé, 1856, north-western Mexico. Possible race *pallidus* likely to be indistinct from nominate or representing N end of cline. Two subspecies recognized.

Subspecies and Distribution.

F. c. cyanopygius (Souancé, 1856) - W Mexico.

F. c. insularis (Ridgway, 1888) - Tres Marias Is. off W Mexico.

Descriptive notes. 13-14 cm; 30-37 g. Green above with turquoise blue lower back, rump, secondary coverts, outer secondaries and underwing-coverts; lighter, grass green on face and undersides, latter sometimes tinged bluish. Female replaces blue with yellowish green. Immature like adult, male with reduced blue. Race *insularis* has darker green upperparts, underparts glaucous, and darker, more cobalt blue; larger.

Habitat. Tropical semi-deciduous to deciduous forest, riparian woodland, plantations, secondary forest, from sea-level to 1400 m.

Food and Feeding. Fruits including small

Ficus, berries and grass seeds, taken from ground.

Breeding. Jun-Jul on Tres Marias Is. perhaps later than on mainland. Nest presumably in tree cavity but apparently still unrecorded. Eggs 3 in captivity, where nestling period was c. 5 weeks.

Movements. Some seasonal wandering seems to occur, notably in the southernmost part of its range.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Common, and apparently little traded locally. Appears to have declined on Tres Marias, but small flocks persist.

Bibliography. Anon. (1983), Forshaw (1965), Friedmann *et al.* (1950), Goddard (1927), Grant (1965, 1966), Grant & Cowan (1964), Howell & Webb (1995a), Konrad (1986), Low (1972), McLellan (1927), Nelson (1899), Pfeffer (1992), Ridgely (1981), van Rossem (1945), Schaldach (1963), Stotz *et al.* (1996), Whitney (1996), Zimmerman & Harry (1951).

257. Green-rumped Parrotlet

Forpus passerinus

French: Toui été **German:** Grünbürzel-Sperlingspapagei **Spanish:** Cotorrita Culiverde
Other common names: Guiana/Common/Blue-winged Parrotlet

Taxonomy. *Psittacus passerinus* Linnaeus, 1758, Surinam.

Forms a superspecies with *F. crassirostris*. Five subspecies recognized.

Subspecies and Distribution.

F. p. cyanophanes (Todd, 1915) - N Colombia.

F. p. viridissimus (Lafresnaye, 1848) - N Venezuela perhaps into NE Colombia; also Trinidad, where possibly introduced.

F. p. passerinus (Linnaeus, 1758) - the Guianas, mainly near coast.

F. p. cyanochlorus (Schlegel, 1864) - Roraima, NW Brazil.

F. p. deliciosus (Ridgway, 1888) - lower Amazon in Brazil.

Introduced (*viridissimus*) to Curaçao in Netherlands Antilles, and (perhaps same race) to Jamaica and Barbados.

Descriptive notes. 12-13 cm; 20-28 g. Green, lighter on forehead, cheeks, underparts, back and rump (this last brightest, but sometimes washed blue); grey tinge on hindneck; primary coverts and underwing-coverts dark blue, secondaries blue; greater coverts pale blue. Female replaces blue markings with green, forehead more yellowish. Immature like adult. Race *viridissimus* darker green throughout; *cyanophanes* with more blue on closed wing; *cyanochlorus* like *passerinus* but female more yellowish; *deliciosus* with pale blue tinge on rump, darker blue on secondaries, female with strong yellow tinge on forehead.

Habitat. Semi-open lowland areas such as dry deciduous and gallery forest edge, second growth, thornbush and cactus scrub, mangroves, less common in savanna, though often moving into open grassland to feed; also in city parks, ranchland and agricultural areas. Up to 1800 m.

Food and Feeding. Grass seeds, especially *Croton hirtus*, *Hyptis suaveolens*, *Wissadula*, *Cyperus*, *Scoparia dulcis* and *Melochia parviflora*, often obtained by settling on grass stems and allowing weight to bend seedhead to ground. Also berries (e.g. of mistletoes), fruits such as *Anona* and *Psidium guajava*, leafbuds, blossoms; seeds of *Lagerstroemia indica* and sunflowers.

Breeding. Season probably extended in most of range. Most months from Feb to Aug on Trinidad; Feb, Jun, Aug and Nov in Surinam; Apr-Aug in Venezuela; May-Jun, Aug and Oct-Nov in Colombia. Nest in

hollow stump, limb or trunk, or arboreal termitarium; also more rarely in palm frond base and artificial site such as end of piping. Usually 5 eggs (2-11); incubation takes around 14 days, but hatching staggered; nestling period 4-5 weeks. In captivity young almost immediately independent, suggesting scope for second brood, and in wild half of females attempt repeat breeding.

Movements. Occurs, perhaps only as a seasonal upslope movement, in lower subtropical zone.

Status and Conservation. Not globally threatened. CITES II. Generally common and probably increasing with clearance of forest within its range. Heavily traded in and from Venezuela. Appears to have colonized Trinidad this century, perhaps originally through introduction; now common there, and rapidly spreading on Tobago, where recently introduced.

Bibliography. Beissinger & Stoleson (1991), Beissinger & Waltman (1991), Bond (1985), Curlee & Beissinger (1995), Desenne & Strahl (1991, 1994), Enehjelm (1951), ffrench (1991), ffrench & ffrench (1966), Gruber (1981), Haverschmidt & Mees (1994), Hilty & Brown (1986), Lever (1987), Low (1972), Meier (1984), Meyer de Schauensee & Phelps (1978), Pinto (1964), Ridgely (1981), Sick (1985, 1993), Snyder (1966), Stoleson & Beissinger (1994), Stotz *et al.* (1996), Tostain *et al.* (1992), Vriends (1979), Waltman & Beissinger (1992), Wetmore (1939), Whitney (1996).

258. Blue-winged Parrotlet

Forpus crassirostris

French: Toui de Spix **German:** Blauflügel-Sperlingspapagei **Spanish:** Cotorrita Aliazul

Taxonomy. *Psittacula crassirostris* Taczanowski, 1883, Yurimaguas, Peru.

Forms a superspecies with *F. passerinus*. Commonly referred to as *F. xanthopterygius*, which was shown in 1905 to have been applied to an immature *Brotogeris chiriri*, but which was mistakenly reinstated in 1945 when present species was separated from *F. passerinus*. Isolated race *spengeli* might belong with *F. cyanopygius* of Mexico; proposed race *olallae* included within nominate. Five subspecies currently recognized.

Subspecies and Distribution.

F. c. spengeli (Hartlaub, 1885) - N Colombia.

F. c. crassirostris (Taczanowski, 1883) - SE Colombia, E Ecuador and N Peru to W Brazil.

F. c. flavescens (Salvadori, 1891) - SE Peru and E Bolivia.

F. c. flavissimus Hellmayr, 1929 - NE Brazil.

F. c. vividus (Ridgway, 1888) - E & SE Brazil, Paraguay and N Argentina.

Descriptive notes. 12-13 cm; 30 g. Green, slightly lighter and yellower below; bright emerald green around eye; bend of wing, primary and secondary coverts, underwing-coverts, lower back and rump blue. Female replaces all blue with green. Immature like equivalent adult, male with reduced blue. Race *flavissimus* has forehead, cheeks and throat lemon yellow (male), yellowish face (female); *vividus* has darker blue (male) or more yellowish tint (female) than *crassirostris*; *flavescens* has yellowish tinge, male with blue paler; *spengeli* has turquoise blue on back and rump, male has violet blue in wing, female has yellowish forehead.

lowish forehead.

Habitat. In C of range gallery forest, light riparian growth, matorral (patchy, varied riverine thickets), lowland rain forest edge and secondary growth, but at edges of range it also occupies savanna, palm groves and semi-arid scrub as well as pastures, parkland and suburbs. Ranges up to 1200 m.

Food and Feeding. Mainly fruit and seeds of plants in secondary vegetation, including grass seed taken from ground; specific items include seeds of *Mikania*, *Cecropia glaziovii*, *Trema micrantha*, flowers of *Ambrosia polystachya*, *Maregravia polyantha*.

Breeding. Precise timing unclear; occupied nest-hole in Jul, Colombia. Nest in hole in tree (e.g. *Cecropia*), in termite nest, or in disused nest of Rufous Hornero (*Furnarius rufus*), with grass stems used to provide flooring; rarely in Red-rumped Cacique (*Cacicus haemorrhous*) nest. Eggs 4-7, 8 in captivity, when incubation (by female only) was estimated at c. 18 days, nestling period c. 4 weeks.

Movements. Seasonal movements related to flowering and fruiting of various communities of plants are reported for Argentina, while in Atlantic Forest, Brazil, it is an altitudinal migrant.

Status and Conservation. Not globally threatened. CITES II. Common over most of range, and possibly expanding numbers with fragmentation of Amazonian forest. Possible decline, Paraguay, where reported common at start of century and now generally uncommon to rare. Trade appears low.

Bibliography. Canevari *et al.* (1991), Collar (1997), Contreras (1990), Contreras *et al.* (1990), Darrieu (1983d), Galetti (1996), Guix (1995), Hayes (1995), Hayes *et al.* (1990), Hilty & Brown (1986), López (1992), Low (1972), Mitchell (1957), Mobbs (1981), Norez & Yzurieta (1994), O'Neill (1981), Olmos (1993), de la Peña (1988), Pinto (1945b), Pizo *et al.* (1995), Ridgely (1981), do Rosário (1996), Short (1975), Sick (1985, 1993), Stotz *et al.* (1996), Tallman *et al.* (1977), Terborgh & Weske (1969), Watson (1905), Whitney (1996).

259. Spectacled Parrotlet

Forpus conspicillatus

French: Toui à lunettes **German:** Brillensperlingspapagei **Spanish:** Cotorrita de Anteojos

Taxonomy. *Psittacula conspicillata* Lafresnaye, 1848, Honda, upper Magdalena Valley, Colombia. Proposed race "*pallascens*", from Patía Valley of SW Colombia, is a *nomen nudum*. Three subspecies recognized.

Subspecies and Distribution.

F. c. conspicillatus (Lafresnaye, 1848) - E Panama and NC Colombia.

F. c. metae Borrero & Camacho, 1961 - C Colombia E to W Venezuela.

F. c. caucae (Chapman, 1915) - SW Colombia; possibly recorded (most likely this race) in W Ecuador.

Descriptive notes. 12-13 cm; 24-28 g. Grass green on forehead, face and throat, duller on back, wings and tail, with deep blue lower back, rump and secondaries, paler blue on shoulder and greater

On following pages: 260. Dusky-billed Parrotlet (*Forpus sclateri*); 261. Pacific Parrotlet (*Forpus coelestis*); 262. Yellow-faced Parrotlet (*Forpus xanthops*); 263. Grey-cheeked Parakeet (*Brotogeris pyrrhopterus*); 267. Orange-chinned Parakeet (*Brotogeris jugularis*); 268. Cobalt-winged Parakeet (*Brotogeris cyanoptera*); 269. Golden-winged Parakeet (*Brotogeris chrysopterus*); 270. Tui Parakeet (*Brotogeris sanctithomae*).

wing-coverts; bluish green underwing-coverts; bluish around and behind eye; silvery green on undersides. Female lacks all blue, and is yellowish green on undersides. Immature like adult, male with less blue. Race *metae* is more yellow green below, blue round eye reduced; *cauca* has lighter blue on back and wings, larger bill, with populations in arid Patía and Dagua valleys paler still.

Habitat. Lowland evergreen forest edge, gallery forest, semi-open deciduous woodland, llanos, secondary growth, thorn scrub, pastures and clearings, 100-1800 m, occasionally to 2600 m.

Food and Feeding. Grass seeds taken from ground, berries, fruits, buds and probably blossoms from bushes.

Breeding. Dec-Mar in Colombia. Nest a hole in a stump, tree, termitarium or fence post made of bamboo (*Guadua*), often as low as 1-2 m from ground. Eggs 1-6.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Some habitat destruction and illegal trade has affected the species in Venezuela and it is fairly uncommon in Panama, but in Colombia it has benefited from forest clearance, increasing its range and becoming abundant in many areas.

Bibliography. Desenne & Strahl (1991, 1994), Fjeldså & Krabbe (1990), Garnetke-Stollmann & Franck (1990, 1991), Gómez (1991), Haffer (1986), Hilty & Brown (1986), Kattan & Gómez (1992), Low (1972), Meyer de Schauensee & Phelps (1978), Miller (1947, 1963), Molenda & Molenda (1994), Munves (1975), Olivares (1969), Ridgely (1981), Ridgely & Gwynne (1989), Stotz *et al.* (1996), Wanker *et al.* (1996), Wetmore (1968), Whitney (1996), Zinniker (1987).

260. Dusky-billed Parrotlet

Forpus sclateri

French: Toui de Sclater

Spanish: Cotorrita de Sclater

German: Schwarzschnabel-Sperlingspapagei

Other common names: Sclater's Parrotlet

Taxonomy. *Psittacula Sclateri* G. R. Gray, 1859, Rio Javari, Peru.

Precise boundaries between the two races remain unclear. Two subspecies recognized.

Subspecies and Distribution.

F. s. eidos J. L. Peters, 1937 - E Colombia and S & SE Venezuela (also outlying in Carabobo) through Guyana (two records) and S French Guiana to N Brazil.

F. s. sclateri (G. R. Gray, 1859) - SE Colombia, NE Ecuador, E Peru and N Bolivia E through Amazon basin to N Brazil S of Amazon delta.

Descriptive notes. 13 cm; 28 g. Darker green than congeners, forehead, cheeks and chin emerald, underparts more glaucous; lower back, rump and large panel on wing dark blue; upper mandible dark brown-grey. Female replaces blue with green, generally paler and more yellowish on underparts. Immature undescribed.

Habitat. Clearings, edge and other secondary habitats within tropical lowland rain forest and, perhaps most importantly, seasonally flooded várzea forest along rivers; locally in Ecuador up to 1000 m.

Food and Feeding. Seeds of *Cecropia*

miparia; no other information.

Breeding. Possibly Jul in Peru. Nest probably in hole in dead tree, etc. No other information.

Movements. Nothing is known.

Status and Conservation. Not globally threatened. CITES II. Fairly common in W Amazonia, becoming scarcer in E where once common; but increasing in numbers in Colombia. Little if at all traded.

Bibliography. Allen (1995), Desenne (1994), Desenne & Strahl (1991, 1994), Friedmann (1948b), Hilty & Brown (1986), Low (1972), Meyer de Schauensee & Phelps (1978), O'Neill (1974, 1981), Pearson (1972), Pinto (1964), Ridgely (1981), Sick (1985, 1993), Snyder (1966), Stotz *et al.* (1996), Tallman *et al.* (1977), Tostain *et al.* (1992), Wheatley (1994), Whitney (1996).

261. Pacific Parrotlet

Forpus coelestis

French: Toui céleste

German: Himmelsperlingspapagei

Spanish: Cotorrita de Piura

Other common names: Celestial/Western Parrotlet

Taxonomy. *Agapornis coelestis* Lesson, 1847, Peru.

Forms a superspecies with *F. xanthops*, with which has been considered conspecific. Monotypic.

Distribution. W Ecuador to NW Peru.

Descriptive notes. 13 cm; 24-28 g. Light green crown and face with bluish postocular stripe merging into blue-grey of hindcrown, nape and sides of neck, this in turn shading to green-grey on back and wings; lower back, rump and large patch on wing dark blue; underparts green with grey flanks; tail dull green. Female replaces all blue with emerald green, apart from blue to bluish green tinge from eye to nape. Immature like adult, but male with less blue.

Habitat. Arid lowland scrub, semi-open tropical deciduous woodland, gallery forest and secondary growth, locally and more sparsely in

humid vegetation, up to 1500 m.

Food and Feeding. Berries taken amid branches, cactus and *Tamarindus* fruits, seeds taken from the ground.

Breeding. Jan-May in Ecuador. Nests in any natural or artificial cavity, from holes in trees, branches, fence posts and telephone poles to the ends of pipes and bamboo rafters; also old mud nests of Pale-legged Hornero (*Furnarius leucopus*) and large stick nests of Necklaced Spinetail (*Synallaxis stictothorax*) and Fasciated Wren (*Campylorhynchus fasciatus*); no lining. Eggs 4-6, but family parties supposedly of 10 suggest more possible; incubation 17 days; nestling period c. 30 days. Second brood sometimes reared, commencing as little as 7-8 days after fledging.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Common to abundant, and apparently able to withstand both moderate levels of trade and moderate levels of habitat conversion to agriculture, so long as some trees are left.

Bibliography. Best & Clarke (1991), Best & Kessler (1995), Bloch *et al.* (1991), Boorer (1964), Brockner (1994), Butler (1979), Ginsberg (1984), Lantermann (1996), Low (1972), Marchant (1960), O'Neill (1981), Olrog (1968), Parker *et al.* (1982), Ridgely (1981), Stotz *et al.* (1996), Taylor (1995a), Wheatley (1994), Whitney (1996), Williams *et al.* (1996).

262. Yellow-faced Parrotlet

Forpus xanthops

French: Toui à tête jaune

Spanish: Cotorrita Carigualda

German: Gelbmasken-Sperlingspapagei

Taxonomy. *Psittacula xanthops* Salvin, 1895, Viña, Huamachuco.

Has been judged a subspecies of *F. coelestis*, to which it is clearly closely related; but size and colour differences suggest better treated as members of a superspecies. Monotypic.

Distribution. NC Peru in upper Marañón Valley.

Descriptive notes. 15 cm. Yellow crown and face with bluish postocular stripe merging into bluish grey of hindcrown and nape, this in turn merging into olive grey on sides of neck, back and wings; lower back, rump, uppertail-coverts and large patch on wing dark blue, paler on secondary coverts; underparts greenish yellow; underwing-coverts dark blue; tail green. Female has back and rump pale blue, less blue in wing. Immature undescribed.

Habitat. Cactus-*Prosopis* montane desert scrub, dry deciduous forest and riparian thickets at 600-1800 m; a roost was in *Ginerium* canebrake.

Food and Feeding. Fruits or seeds of a leguminous tree *Cercidium praecox*, cactus fruits and seeds, flowers of *Bombax discolor*; observed on the ground where doubtless feeding on grass seed, and will feed on ripe wheat.

Breeding. Mar-Apr. Nests reportedly placed in natural dirt and rock walls along R Marañón, in colonies of up to 70 birds; old woodpecker cavities also used. In captivity: 3-6 eggs; incubation 21-22 days; and nestling period 35-40 days.

Movements. Apparently sedentary.

Status and Conservation. **VULNERABLE.** CITES II. A BirdLife "restricted-range" species. Until relatively recently (c. 1980) considered common to abundant, but heavily traded internally apparently since 1963, with around 600 birds reportedly captured every week in the period 1981-1984, after which legal protection was introduced. Moreover, steady deterioration of habitat in the face of cultivation and goat damage may pose serious problems in parts of its highly restricted range. It occurs in no protected area, but is still considered a pest in two localities.

Bibliography. Anon. (1993), Begazo (1996), Bond (1955), Collar (1996), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Davies *et al.* (1994), Dorst (1957a, 1957b), Girdler & Austin (1982), Inskipp *et al.* (1988), Low (1972), Mitchell (1991), O'Neill (1981, 1987), Parker *et al.* (1982), Pulido (1991), Ridgely (1981), Robiller (1990), St. Vaughan (1983), Stotz *et al.* (1996), Wege & Long (1995), Whitney (1996).

Genus BROTOGERIS Vigors, 1825

263. Plain Parakeet

Brotogeris tirica

French: Toui tirica

German: Tirikassittich

Spanish: Catita Tirica

Taxonomy. *Psittacus Tirica* J. F. Gmelin, 1788, Brazil.

Monotypic.

Distribution. CE Brazil from Alagoas S to at least Santa Catarina and ranging inland as far as E Goiás.

Descriptive notes. 23 cm; 63 g. Green, slightly more yellowish on undersides; minor bluish tinge on nape; shoulder bronze green, flight-feathers and underside of tail bluish green. Blue mutation on São Paulo coast. Immature has less blue in wings and shorter tail.

Habitat. Canopy and edge of lowland and montane rain forest, secondary growth, semi-open cultivated land with scattered groves, plantations and city parks, generally in lowlands but ranging up to 1200 m.

Food and Feeding. Pulp of *Posoqueria latifolia*, seeds of *Ficus glabra*, *Trema micrantha*, *Xylopia brasiliensis*, *Vriesea*,

Rhipsalis, *Cecropia glazioui*, *Hieronyma alchorneoides*, *Merostachis*, seeds and flowers of *Tibouchina mutabilis* and the mistletoe *Psittacanthus*, flowers of *Norantea brasiliensis* and *Eucalyptus*, nectar of *Pseudobombax*, possibly insects and their larvae.

Breeding. Probably Sept-Dec, the usual breeding season in SE Brazil, with records of nest in Sept and young in Jan. Nest in hollow in tree. In captivity: 4 eggs; incubation, only by female, lasted c. 26 days; young fledged at 7 weeks.

Movements. Shifts in numbers occur, reflecting local seasonal movements.

Status and Conservation. Not globally threatened. CITES II. Common in many parts of its range, and probably now stable after centuries of slow decline as agriculture cleared out trees in many areas. Tolerates changes far more than any other parrot endemic to SE Brazil, as confirmed by presence in heart of São Paulo. Present in many protected areas including Itatiaia National Park. Rare in captivity, and export banned from Brazil.

Bibliography. Derks (1997), Dubs (1992), Forrester (1993), Guix (1995), Guix *et al.* (1992), Inskipp *et al.* (1988), Lovell-Keays (1914b), Low (1972), Mitchell (1957), Pinto (1935, 1964), Pizo *et al.* (1995), Ridgely (1981), do Rosário (1996), Sick (1985, 1993), Stotz *et al.* (1996), Teixeira *et al.* (1986), Vriends (1979), Whitney (1996), Willis & Oniki (1981).

264. Canary-winged Parakeet

Brotogeris versicolurus

French: Toui à ailes variées **German:** Weißflügelsittich **Spanish:** Catita Versicolor

Taxonomy. *Psittacus versicolurus* P. L. S. Müller, 1776, Cayenne.

Often treated as conspecific with *B. chiriri*, but the two are reported to be sympatric without interbreeding in E Pará. Monotypic.

Distribution. Amazon basin from SE Colombia and NE Peru through Brazil to coastal Pará, and N into French Guiana. Feral populations in Lima, Peru, and on Puerto Rico and mainland USA.

Descriptive notes. 22 cm; 52-68 g. Green, darker on back; forehead and face slightly bluish, lores bare; inner primaries and secondaries white, secondary coverts yellow.

Habitat. River island vegetation, seasonally inundated várzea forest, secondary forest and clearings near settlements.

Food and Feeding. Virtually unknown in wild conditions. Seeds and fruit have been found in stomachs. Wild birds have fed on cultivated Inga fruits in gardens, Colombia, and feral birds (either this species or *B. chiriri*), USA, have adapted to various exotic food sources including blossoms and nectar.

Breeding. Young for sale in Jul in Peru. Nest in hole in tree. Probably 4-5 eggs.

Movements. No information. Probably largely sedentary.

Status and Conservation. Not globally threatened. CITES II. Common to abundant in most of range including Peru, Pará and Amapá, though generally uncommon in SE Colombia.

Bibliography. Anon. (1993), Arrowood (1981, 1986, 1991), Derks (1997), Dugand & Borrero (1946), Fjeldsá & Krabbe (1990), Goodfellow (1900), Hilty & Brown (1986), Inskipp *et al.* (1988), Lever (1987), Low (1972), O'Neill (1981), Pérez-Rivera (1984), Pérez-Rivera *et al.* (1985), Pinto (1964), Ridgely (1981), da Rocha *et al.* (1988), Short (1975), Shrods (1974), Sick (1985, 1993), Stone (1929), Stotz *et al.* (1996), Tostain *et al.* (1992), Whitney (1996).

265. Yellow-chevroned Parakeet

Brotogeris chiriri

French: Toui à ailes jaunes **German:** Gelbflügelsittich **Spanish:** Catita Chiriri
Other common names: Chiriri Parakeet

Taxonomy. *Psittacus chiriri* Vieillot, 1818, Paraguay.

Often treated as conspecific with *B. versicolurus*, but the two are reported to be sympatric without interbreeding in E Pará. Two subspecies recognized.

Subspecies and Distribution.

B. c. behni Neumann, 1931 - C & S Bolivia.

B. c. chiriri (Vieillot, 1818) - N Bolivia, Paraguay and N Argentina E to NE, C & SE Brazil (S to São Paulo).

Descriptive notes. 20-25 cm. Grass green, yellowish on underparts and underside of tail; primaries tinged blue at bases; outer secondary coverts yellow. Immatures similar. Race *behni* larger, lacking yellowish tinge to underparts and tail.

Habitat. Gallery forest in open country, subtropical forest, relatively open woodland, seasonally flooded grassland and *caatinga* vegetation, up to 1560 m.

Food and Feeding. No information.

Breeding. Nest-site prospection in Jan in Mato Grosso.

Movements. Some seasonal movements, undefined, may occur in W Paraguay, and large flocks have been observed in Nov, Mato Grosso, before breaking up into pairs in Jan, which implies some accumulative and dispersive behaviour.

Status and Conservation. Not globally threatened. CITES II. Common to abundant in most of range, including Maranhão, Goiás, Mato Grosso, but rare to uncommon in Argentina although 46,522 birds were exported from that country in 1985-1989, evidently having originated further N.

Bibliography. Anon. (1993), Brooks *et al.* (1993), Canevari *et al.* (1991), Contreras *et al.* (1990), Dabbene (1914), Derks (1997), Fjeldsá & Krabbe (1990), Guix (1995), Hayes (1995), Low (1972), Naumburg (1930), Navas & Bó (1996), Nores & Yzurieta (1994), Orfila (1938), de la Peña (1988), Pérez (1990), Pinto (1964), Ridgely (1981), Schubart *et al.* (1965), Short (1975), Sick (1985, 1993), Stotz *et al.* (1996), Vriends (1979), Whitney (1996).

266. Grey-cheeked Parakeet

Brotogeris pyrrhopterus

French: Toui flamboyant **German:** Feuerflügelsittich **Spanish:** Catita Macareña

Taxonomy. *Psittacus pyrrhopterus* Latham, 1801, Brazil; error = Guayaquil, Ecuador. Monotypic.

Distribution. W & SW Ecuador and extreme NW Peru.

Descriptive notes. 20 cm; 60-68 g. Crown bluish green, cheeks pale grey; body and wings green, lighter below; underwing-coverts orange red. Immatures have green crowns.

Habitat. Evergreen and disturbed humid forest, deciduous *Ceiba trichistandra* forest and woodland (birds seemingly most numerous in this habitat), extending into arid *Acacia*-dominated scrubland and semi-open cultivated areas, only up to 300 m in N of range but up to 1550 m in S.

Food and Feeding. Petals and seeds of *Erythrina* trees, flowers and seeds of *Chorisa*, flowers of *Cavanillesia platanifolia*, fruit of

Ceiba and *Ficus*, and catkins of *Cecropia*. Flocks in vicinity of banana plantations were presumably using this food source, and some birds are reportedly trapped for trade while raiding crops.

Breeding. Most activity probably coincides with the wet season, Jan-Mar, although specimens from Jul had slightly enlarged gonads, and copulation witnessed in Aug. Large trees with hollow limbs apparently needed for nest-holes; termite mounds also used. In captivity: 4-7 eggs; young fledge at 6 weeks.

Movements. The scarcity of the species in certain apparently suitable areas may reflect seasonal displacements, which are thought likely to occur.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. Formerly abundant, now only locally common. Present in four protected areas: Cerro Blanco Reserve, Arenillas Military Reserve and Manglares-Churute Ecological Reserve in Ecuador, and Tumbes National Forest in Peru. Large-scale conversion of forest to agriculture has caused substantial reduction of presence within historical range, this being compounded by substantial chronic exploitation for trade (both local and international) and, possibly, depletion of suitable natural nest-sites. Total of 59,320 birds, almost entirely from Peru (but very possibly originating in Ecuador) reported as having been imported by CITES countries, 1983-1988, representing absolute minimum, and only international trade; moreover, most birds are captured as nestlings and the mortality rate is not known. The world population of wild birds is now judged only 15,000; both range states now have bans on international trade.

Bibliography. Alemán (1994), Anderdon (1994), Beissinger & Snyder (1992), Best & Clarke (1991), Best & Kessler (1995), Best, Checker *et al.* (1996), Best, Clarke *et al.* (1993), Best, Krabbe *et al.* (1995), Bloch *et al.* (1991), Brosset (1964), Butler (1979), Chapman (1926), Collar (1996), Collar & Andrew (1988), Derks (1997), Germeau (1994), Hampe (1939), Harris (1985, 1993a), Inskipp & Corrigan (1992), Low (1972, 1987b), O'Neill (1981), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1995), Ridgely (1981), Stotz *et al.* (1996), Vriends (1979), Whitney (1996), Williams & Tobias (1994), Worth (1993).

267. Orange-chinned Parakeet

Brotogeris jugularis

French: Toui à menton d'or **German:** Tovisittich **Spanish:** Catita Churica
Other common names: Tovi Parakeet

Taxonomy. *Psittacus jugularis* P. L. S. Müller, 1776, Bonda, Santa Marta, Colombia.

Possibly forms a superspecies with *F. cyanoptera* and *F. chrysopterus*. Two subspecies recognized.

Subspecies and Distribution.

B. j. jugularis (P. L. S. Müller, 1776) - SW Mexico through Central America mostly on Pacific slope to N Colombia and NW Venezuela.

B. j. exsul Todd, 1917 - E Colombia and W Venezuela.

Descriptive notes. 18-19 cm; 53-65 g. Head bright green with bluish wash on crown, white eye-ring and pale bill, small orange patch on chin; underparts bright green, bluish on thighs and vent; upperparts and tail bluish green with brown "shoulders", yellow underwing-coverts; amount of yellow in plumage rather variable. Immature similar. Race *exsul* has all-green underparts, darker shoulders with more olive in mantle, smaller, paler chin-patch.

Habitat. Open dry country with scattered trees, llanos, semi-deciduous and deciduous woodland, semi-open, secondary and gallery forest, plantations, cultivated areas and parks and tree-

shaded areas of towns, usually avoiding or less common in evergreen forest canopy and edge. Ranges up to 1400 m.

Food and Feeding. Fruits and seeds of e.g. *Ficus*, *Ceiba*, *Bombax*, *Byrsonima*, *Cecropia*, *Muntingia*, nectar and blossoms of e.g. guava, balsa and *Erythrina*; can cause damage to cultivated fruit.

Breeding. Jan-Apr. Nest in old woodpecker hole, palm stub, excavated by pair in termitarium, or in natural cavity, sometimes communally in one large rotten snag. Eggs 4-7, with 8 young reported from one nest; incubation in captivity lasted around three weeks.

Movements. Wanders locally after breeding, El Salvador.

Status and Conservation. Not globally threatened. CITES II. Common to abundant throughout most of range, but uncommon in Oaxaca, Mexico.

Bibliography. Binford (1989), Chapman *et al.* (1989), Derks (1997), Dickey & van Rossem (1938), Eisenmann (1961, 1968), Harrison & Holyoak (1970), Hilty & Brown (1986), Hood (1961), Howell, S.N.G. & Webb (1995a), Howell, T.R. (1957), Janzen (1981), Land (1970), Lever (1987), Low (1972), Meyer de Schauensee & Phelps (1978), Monroe (1968), Power (1966, 1967), Ridgely (1981), Ridgely & Gwynne (1989), Rowley (1984), Slud (1964), Sules & Skutch (1989), Stotz *et al.* (1996), Vriends (1979), Wetmore (1957, 1968), Whitney (1996).

268. Cobalt-winged Parakeet

Brotogeris cyanoptera

French: Toui de Deville **German:** Kobaltflügelsittich **Spanish:** Catita Aliazul

Taxonomy. *Sittace cyanoptera* Salvadori, 1891, Mission de Sarayacu and Amazon River.

Forms a parapatric species pair with *B. chrysopterus*, and these two may form superspecies with *B. jugularis*. Race *gustavi* may be separate species, although intermediates between this and nominate race have been found in lower Huallaga Valley. Three subspecies normally recognized.

Subspecies and Distribution.

B. c. cyanopectera (Salvadori, 1891) - SE Colombia and S Venezuela to E Ecuador, E Peru and WC Brazil.

B. c. gustavi Berlepsch, 1889 - upper Huallaga, N Peru.

B. c. beniensis Gyldestolpe, 1941 - N Bolivia.

Descriptive notes. 18-20 cm; mean 67 g. Green, darker on uppersides; forehead yellowish, crown and nape tinged blue, eye-ring whitish, chin orange; flight-feathers blue, tail green with blue centre. Immature duller. Race *gustavi* has little blue on head, yellow on carpal edge; *beniensis* paler, combining bluish tinge on head with yellow on carpal edge.

Habitat. Lowland rain forest (commoner on higher areas), humid second growth, forest edges, seasonally inundated *várzea* forest, riverbanks, partly cleared areas, savanna and llanos; reaches over 1000 m in W of range, but only occasional at 1350 m.

Food and Feeding. Little information. Recorded visiting flowering and fruiting trees, and eating *Cecropia* catkins.

Breeding. Little information. Evidence of breeding Jun-Jul in W of range, including pairs at holes in trees. In captivity: 5 eggs; hatching occurred in 24 days.

Movements. Apparently sedentary, with some possibly seasonal upslope wandering.

Status and Conservation. Not globally threatened. CITES II. Common throughout range, but with no recent evidence of trade, hence rare in captivity. Present in Manu National Park, Peru, where density reaches 16 pairs/km².

Bibliography. Allen (1995), Clarke & Clarke (1987), Davis (1986), Derks (1997), Desenne & Strahl (1991, 1994), Dugand & Borrero (1948), Friedmann (1948b), Harris (1984), Hilty & Brown (1986), Inskipp *et al.* (1988), Low (1972, 1987b), Meyer de Schauensee & Phelps (1978), O'Neill (1974, 1981), O'Neill & Pearson (1974), Pearson (1972, 1975c), Pinto (1964), Ridgely (1981), Scott (1988), Sick (1985, 1993), Stotz *et al.* (1996), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Whitney (1996).

269. Golden-winged Parakeet

Brotogeris chrysopterus

French: Toui para

German: Braunkinnsittich

Spanish: Catita Alidorada

Taxonomy. *Psittacus chrysopterus* Linnaeus, 1766, India; error = Guiana.

Forms a parapatric species pair with *B. cyanopectera*, and these two may form superspecies with *B. jugularis*. Five subspecies recognized.

Subspecies and Distribution.

B. c. chrysopterus (Linnaeus, 1766) - NE Venezuela SE through the Guianas to Roraima and Amapá, CN Brazil.

B. c. tenuifrons Friedmann, 1945 - upper R Negro, NW Brazil.

B. c. solimoensis Gyldestolpe, 1941 - Manaus region, NC Brazil.

B. c. tuipara (J. F. Gmelin, 1788) - R Tapajós E to Maranhão, NC Brazil.

B. c. chrysosoma P. L. Sclater, 1864 - R Madeira S to N Mato Grosso, W Brazil.

Descriptive notes. 16 cm; 47-80 g. Close to *B. cyanopectera* but primary coverts bright orange, chin spot orange brown, blue in flight-feathers greatly reduced; has brownish frontal band. Immatures lack orange in wing. Race *tuipara* has frontal band and chin spot orange, yellow edging to outer tail feathers; *chrysosoma* larger, with yellowish orange forehead and yellow primary coverts; *solimoensis* like *cyanopectera* but frontal band and chin paler; *tenuifrons* like *tuipara* but with no frontal band.

Habitat. Cloud forest to 1200 m N of Orinoco, elsewhere lowland primary rain forest, second-growth along waterways, savanna, coastal sand-ridge woodland, edges and centres of towns in large trees.

Food and Feeding. Largely concentrates on flowers, taking nectar of e.g. *Noranthea*, *Inga laterifolia*, *Erythrina amazonica*, *Virola surinamensis*, *Tabebuia serratifolia*, *Pithecellobium pedicellare*, *Bertholletia*

excelsa, *Allantonia lineata* and possibly *Micropholis melinoneana*; also green seed of *Cecropia miparia*, seed of *Alibutia edulis* and Bombacaceae, seed and pulp of *Ficus* and *Sterculia excelsa*, fruit of the palm *Astrocaryum vulgare*, berries of *Trema micrantha*, and surface algae, insects and snails in pools.

Breeding. Occupied nest-holes in Feb, Apr, Sept and Nov in Surinam; Apr, Jul-Aug and Nov in French Guiana, where numerous flying young observed in May; Sept-Oct and possibly Apr-May in N Mato Grosso. Uses tree-holes and arboreal termitaria. Eggs 3-4. No further information.

Movements. Some irregular wandering suggested by records near Paramaribo, Surinam, in Jul-Aug and Oct 1964 in contrast to other years.

Status and Conservation. Not globally threatened. CITES II. Locally common to abundant, even in cities, in all range states, and is relatively little traded. There have been some local declines in E of range from habitat loss.

Bibliography. Beebe (1916), Derks (1997), Desenne (1994), Desenne & Strahl (1991, 1994), Friedmann (1948b), Friedmann & Smith (1955), Haverschmidt & Mees (1994), Low (1972), Meyer de Schauensee & Phelps (1978), Pinto (1964), Ridgely (1981), Roth (1982), Sick (1985, 1993), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Vriends (1979), Whitney (1996).

270. Tui Parakeet

Brotogeris sanctithomae

French: Toui à front d'or

German: Tuisittich

Spanish: Catita Frentigualda

Taxonomy. *Psittacus St. Thomae* P. L. S. Müller, 1776, Island of St Thomas, substituted by "Brazilian Amazons".

Two subspecies recognized.

Subspecies and Distribution.

B. s. sanctithomae (P. L. S. Müller, 1776) - SE Colombia through Amazonian Brazil into NE & SE Peru and NE Bolivia.

B. s. takatsukasae Neumann, 1931 - lower Amazon basin, NC Brazil.

Descriptive notes. 17 cm; mean 59 g. Generally green, more yellowish below and on rump and tail; bluish tinge on face; lores and forehead yellow; primaries dark green, bluish below. Immature like adult. Race *takatsukasae* has yellow postocular streak.

Habitat. Primarily in secondary growth, lightly wooded grassland and dense scrub on swampy riverbanks, sandbars and islands, and at the edge of *várzea* forest along large rivers and lakes, also in clearings at a short distance from waterbodies.

Food and Feeding. Visits riverside palms (unripe fruit ignored) and *Erythrina* trees, often

taking their blossoms; also manioc and sugarcane plantations. Seen feeding on guaba (*Psidium*) fruits.

Breeding. Jul in Peru; evidence suggests Apr-Jul in Colombia, where nest-holes were noted in termitaria. Six different-sized nestlings reported in one nest. No other information.

Movements. Apparently sedentary.

Status and Conservation. Not globally threatened. CITES II. Locally abundant with very little habitat loss, Brazil, and equally common within the limited areas occupied in Colombia, Peru and Bolivia. Present in Manu National Park, Peru.

Bibliography. Allen (1995), Derks (1997), Harris (1992b, 1994a), Hilty & Brown (1986), Lever (1987), Low (1972), Novaes (1957), O'Neill (1974, 1981), Pearson (1975a), Pinto (1947, 1964), Ridgely (1981), Sick (1985, 1993), Stotz *et al.* (1996), Terborgh *et al.* (1984), Vriends (1979), Wheatley (1994), Whitney (1996).

Genus *NANNOPSITTACA* Ridgway, 1912

271. Tepui Parrotlet

Nannopsittaca panychlora

French: Toui des tépous

German: Tépousittich

Spanish: Cotorrita Tepui

Taxonomy. *Brotagerys* [sic] *panychlora* Salvin and Godman, 1883, Mount Roraima, Guyana. Forms a superspecies with *N. dachilleae*. Monotypic.

Distribution. Higher montane isolates in N, S & E Venezuela, S Guyana and N Brazil.

Descriptive notes. 14 cm; 42 g. Green, paler below; yellow area on chin, lores, under and behind eye; undertail-coverts and carpal yellowish; undersides of flight-feathers and tail bluish green. Female has less yellow. Immature undescribed.

Habitat. Cool humid subtropical forest ranging up to 2200 m, but also the lowlands around the tepuis.

Food and Feeding. Fruiting trees are visited; birds make daily altitudinal flights from higher parts of tepuis to forage in lowest reaches.

Breeding. No information.

Movements. Little known, but apparently seen irregularly and in large flocks at (what was at

least then) the one accessible site, possibly indicating some local nomadism. Also makes altitudinal movements on daily basis, for foraging.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Fairly common, with little habitat loss within its range, and very little trade.

Bibliography. Desenne & Strahl (1991, 1994), Forrester (1993), Low (1972), Mayr & Phelps (1967), McLoughlin (1981), Meyer de Schauensee & Phelps (1978), O'Neill *et al.* (1991), Olrog (1968), Ridgely (1981), Snyder (1966), Stotz *et al.* (1996), Wheatley (1994), Whitney (1996), Willard *et al.* (1991).

272. Amazonian Parrotlet

Nannopsittaca dachilleae

French: Toui de D'Achille

German: Amazonassittich

Spanish: Cotorrita Amazónica

Taxonomy. *Nannopsittaca dachilleae* O'Neill *et al.* 1991, 65 km east-north-east of Pucallpa, right bank of Río Shesha, Ucayali, Peru.

Forms a superspecies with *N. panychlora*. Monotypic.

Distribution. SE Peru and NW Bolivia, and probably adjacent W Brazil.

Descriptive notes. 14 cm; 38-46 g. Green, more yellowish on underparts; forehead, lores and crown pale powdery blue; chin greenish yellow; flight-feathers green on outer webs, dusky black on inner; bill and feet pinkish.

Habitat. Trees and natural secondary vegetation along rivers in lowland tropical forest; not seen in closed-canopy forest or areas disturbed by man. In Bolivia seen in river-edge trees including small *Calocophyllum spruceanum* and *Cecropia membranacea*.

Food and Feeding. Seeds of *Guadua* bamboo, ripe fruits of a *Coussapoa* vine, *Cecropia* catkins, *Vernonia* seeds and fruits or seeds of an

arboreal epiphytic cactus *Rhipsalis*.

Breeding. Apparent nest in hole in clump of epiphytes near top of a 25 m tree seen under inspection in Jul and Sept.

Movements. Nothing is known, but use of bamboo suggests degree of nomadism possible.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. Common to abundant at type locality, and present in Tambopata Reserve and Manu National Park.

Bibliography. Allen (1995), Collar *et al.* (1994), Donahue (1994), O'Neill *et al.* (1991), Parker *et al.* (1991), Shuker (1993), Stotz *et al.* (1996), Wheatley (1994), Whitney (1996).

Genus *TOUIT* G. R. Gray, 1855

273. Lilac-tailed Parrotlet

Touit batavica

French: Toui à sept couleurs

German: Siebenfarbenpapagei

Spanish: Cotorrita Sietecolores

Other common names: Seven-coloured Parrotlet

Taxonomy. *Psittaca Batavica* Boddaert, 1783, Batavia; error = Venezuela. Monotypic.

Distribution. N Venezuela (from Mérida) W to Trinidad and Tobago, Guyana, Surinam and French Guiana to the border with (and possibly in) Amapá, Brazil.

Descriptive notes. 14 cm; 52-72 g. Head yellow, ear-coverts and sides of neck green, nape scaled dusky; back and wings black with greater wing-coverts yellowish green edged green-blue, carpal red; tail purplish rose with black subterminal bar; throat and belly green, breast pale blue; underwing-coverts blue. Immature undescribed.

Habitat. Lowland deciduous forest extending into cloud-forest at 900-1700 m in W of range; elsewhere in undisturbed and disturbed primary forest, secondary forest, although on Trinidad coming to suburban area to roost in large eucalypt in garden.

Food and Feeding. Flowers, nectar, buds, berries, seeds and fruits, apparently mostly taken in the early morning.

Breeding. Fledgling found in Dec in Surinam; Jan-Mar on Trinidad. Nest in arboreal termitarium or hollow limb. Eggs 5-6.

Movements. Irregular wanderers in coastal regions, Surinam, and noted using Portachuelo Pass, Venezuela, Aug-Nov. Some form of movement also appears to occur on Trinidad.

Status and Conservation. Not globally threatened. CITES II. Relatively common on Trinidad. Considered heavily traded in Venezuela, but another source describes it as little kept in captivity owing to high mortality, perhaps related to diverse natural alimentary regime. Present in Henri Pittier National Park, Venezuela.

Bibliography. Belcher & Smooker (1936), Desenne & Strahl (1991, 1994), Fernández-Badillo *et al.* (1994), ffrench (1991), Haverschmidt & Mees (1994), Herklots (1961), Lentino & Portas (1994), Low (1972), Meyer de Schauensee & Phelps (1978), Murphy (1995), Ridgely (1981), Schäfer & Phelps (1954), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Troncoso *et al.* (1995), Wheatley (1994), Whitney (1996).

274. Scarlet-shouldered Parrotlet

Touit huetii

French: Toui de Huet

German: Schwarzstirnpapagei

Spanish: Cotorrita Alirroja

Taxonomy. *Psittacus huetii* Temminck, 1830, upper Amazonia. Monotypic.

Distribution. S & NE Venezuela and adjacent N Guyana, occasionally on Trinidad; disjunct in E Colombia; then from E Ecuador and E Peru to N Bolivia; and Amazonian Brazil from R Aripuanã E to R Tocantins, with a single record from Manaus. It is not known whether the apparent gaps in this range are genuine.

Descriptive notes. 15-16 cm; 58-62 g. Green, paler on underparts; front of face dark with white eye-ring, crown and nape olive brown; upperwing-coverts dark blue, primaries black, carpal, underwing-coverts and axillaries red; undertail-coverts yellow, uppertail green in centre, rest red. Female replaces red of tail with greenish yellow, tipped black. Immature like female but without dark face.

Habitat. Humid lowland, chiefly *terra firme* forest, but also seasonally flooded *várzea* forest, extending usually only to 900 m but at least occasionally up to 1300 m, and considered commoner in upper tropical forest, Peru; in

Venezuela near rivers.

Food and Feeding. No information.

Breeding. Evidence for Apr in S Venezuela; birds with young in N Mato Grosso (Rio Aripuanã), Brazil, indicated their having bred Sept-Dec. No other information.

Movements. Almost certainly nomadic in upper Amazonia, birds rarely being found in one area for more than a few weeks at a time, and records from N Mato Grosso are certainly of post-breeding visitors, apparently in wandering flocks. Flocks recorded on Trinidad in 1974, 1975, 1980.

Status and Conservation. Not globally threatened. CITES II. Although apparently uncommon to rare, this bird is highly unobtrusive and lives in remote areas, so may be commoner than records indicate; or it may be temporally patchy, reflecting nomadism (which might explain the large flocks reported in Guyana). If it is declining, this is likely to be for natural and not human-related reasons. Little trade recorded.

Bibliography. Allen (1995), Boesman (1995), Desenne & Strahl (1991, 1994), ffrench (1991), Hilty & Brown (1986), Low (1972), Meyer de Schauensee & Phelps (1978), O'Neill (1969, 1981), Parker & Remsen (1987), Parker *et al.* (1991), Pinto (1964), Ridgely (1980, 1981), Roth (1982), Sick (1985, 1993), Snyder (1966), Stotz *et al.* (1996), Whitney (1996).

275. Red-fronted Parrotlet

Touit costaricensis

French: Toui du Costa Rica

German: Costa-Rica-Papagei

Spanish: Cotorrita Costarricense

Other common names: Red-winged Parrotlet (when combined with *T. dilectissima*)

Taxonomy. *Urochroma costaricensis* Cory, 1913, near Puerto Limón, Costa Rica.

Sometimes treated as conspecific with *T. dilectissima*. Monotypic.

Distribution. Costa Rica to W Panama.

Descriptive notes. 17 cm; 80 g. Like *T. dilectissima* but forehead to mid-crown red, and subocular red patch more extensive, blue on face much diminished, throat yellowish. Female has less red on head and in wings. Immature has little or no red on head.

Habitat. Cool, very wet montane evergreen forest in the middle altitude subtropical belt and, seasonally, lowland rain forest; enters patchy secondary areas.

On following pages: 276. Blue-fronted Parrotlet (*Touit dilectissima*); 277. Sapphire-rumped Parrotlet (*Touit purpurata*); 278. Brown-backed Parrotlet (*Touit melanonota*); 279. Golden-tailed Parrotlet (*Touit surda*); 280. Spot-winged Parrotlet (*Touit stictoptera*); 281. Black-crowned Parrot (*Pionites melanocephala*); 282. White-bellied Parrot (*Pionites leucogaster*); 283. Vulturine Parrot (*Pionopsitta vulturina*); 284. Brown-hooded Parrot (*Pionopsitta haematotis*); 285. Rose-faced Parrot (*Pionopsitta pulchra*); 286. Orange-cheeked Parrot (*Pionopsitta barrabandi*).

habitat disturbance; apparently not traded.

Bibliography. Anon. (1983), Collar *et al.* (1994), Delgado (1985a), Eisenmann (1955), Hernández-Baños *et al.* (1995), Low (1972), Ridgely (1981), Ridgely & Gwynne (1989), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Taylor, K. (1993), Wetmore (1968), Whitney (1996).

276. Blue-fronted Parrotlet

Touit dilectissima

French: Toui à front bleu **German:** Kronenpapagei **Spanish:** Cotorrita Cariazul
Other common names: Red-winged Parrotlet (when combined with *T. costaricensis*)

Taxonomy. *Urochroma dilectissima* P. L. Sclater and Salvin, 1871, south of Mérida, Venezuela. Sometimes treated as conspecific with *T. costaricensis*. Monotypic.

Distribution. E Panama through NE Colombia to W Venezuela, and S on Pacific slope to NW Ecuador.

in Venezuela.

Food and Feeding. Small fruits have been found in stomachs.

Breeding. Jun in Colombia; evidently May-Jun in Panama. Nest in arboreal termitarium.

Movements. Seasonal movements take birds into lowlands and up to 3000 m.

Status and Conservation. Not globally threatened. CITES II. Uncommon to rare; part of range in N Colombia now deforested, and suffers from habitat loss within a small range, Venezuela; however, much habitat remains, little trade exists, and it is relatively secure.

Bibliography. Butler (1979), Carriker (1959), Desenne & Strahl (1991, 1994), Dugand (1948), Hilty (1977), Hilty & Brown (1986), Low (1972), Meyer de Schauensee & Phelps (1978), Olivares (1957), Phelps & Phelps (1958), Ridgely (1981), Ridgely & Gwynne (1989), Stotz *et al.* (1996), Wetmore (1968), Whitney (1996).

277. Sapphire-rumped Parrotlet

Touit purpurata

French: Toui à queue pourprée **German:** Purpurschwanzpapagei **Spanish:** Cotorrita Purpurada

Taxonomy. *Psittacus purpuratus* J. F. Gmelin, 1788, Cayenne.

Two subspecies recognized.

Subspecies and Distribution.

T. p. viridiceps Chapman, 1929 - S Venezuela S from Cerro Duida into N Brazil on upper R Negro and W to SE Colombia, E Ecuador (one record) and NE Peru.

T. p. purpurata (J. F. Gmelin, 1788) - S Venezuela E from Cerro Duida through the Guianas to N Brazil, including lower R Negro, as far as Maranhão.

also savanna woodland, forest edge and inselberg borders in Guianas, and isolated woodlots in cleared terrain.

Food and Feeding. Recorded feeding on fruit of *Ficus*, *Clusia grandiflora*, *Pourouma guianensis* and trees of Sapotaceae and Myrtaceae.

Breeding. Mar in Venezuela; Apr and Nov in the Guianas; female excavating nest in Nov, Colombia. This nest was a hole in a dead tree in flooded forest; arboreal termitaria also used. Eggs reportedly 3-5.

Movements. Unknown.

Status and Conservation. Not globally threatened. CITES II. Uncommon, never in large numbers, but inconspicuous and therefore perhaps underrecorded. Several important reserves exist within its range, notably in Brazil, and the species appears never to have been traded. Some habitat loss may have affected numbers, although birds persist in partially cleared land.

Food and Feeding. Fruits from trees and epiphytes, including melastomes, ericads like *Cavendishia*, and *Clusia*.

Breeding. Probably breeds in dry season. Eggs probably 2-3, given family parties of 4-5.

Movements. Resident, but extensive altitudinal migrant, rising to 3000 m in dry season and descending sometimes to sea-level in wet.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. Uncommon to rare, although probably much overlooked and tolerant of a degree of

Bibliography. Desenne (1994), Desenne & Strahl (1991, 1994), Dugand & Borrero (1948), Friedmann (1948b), Haverschmidt & Mees (1994), Hilty & Brown (1986), Keller (1995), Low (1972), Meyer de Schauensee & Phelps (1978), Pinto (1964), Ridgely (1981), Sassi (1947), Sick (1985, 1993), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Whitney (1996).

278. Brown-backed Parrotlet

Touit melanonota

French: Toui à dos noir **German:** Braunrückenpapagei **Spanish:** Cotorrita Dorsinegra
Other common names: Black-eared Parrotlet

Taxonomy. *Psittacus melanonotus* Wied, 1820, Brazil. Monotypic.

Distribution. E Brazil in Bahia (19th century), Rio de Janeiro and São Paulo.

Descriptive notes. 15 cm. Green, paler and brighter on face, darker on crown and upper-sides, but scapulars and back blackish brown; flanks bluish grey; lateral tail feathers red tipped black. Female has flanks duller. Immature undescribed.

Habitat. Humid forest, chiefly on lower montane slopes at 500–1000 m, even up to 1700 m, sometimes in rain forest and sand-plain forest at sea-level.

Food and Feeding. Fruits of *Rapanea acuminata*, seeds and berries.

Breeding. No information. Presumably Sept-Oct at start of rains, like most E Brazil

endemics.

Movements. Movements to lower levels may be seasonal in nature, and in the nineteenth century birds were thought to wander more widely in winter (Jun).

Status and Conservation. **ENDANGERED.** CITES II. A BirdLife "restricted-range" species. Generally rare within a very limited range, with habitat destruction continuing and the great majority of recent records coming from well scattered protected areas: Desengano State Park, Itatiaia National Park, Serra dos Órgãos National Park, Tijuca National Park and Pedra Branca State Park (Rio de Janeiro), Ubatuba Experimental Station, Serra do Mar State Park, Iguape Environmental Protection Area and Ilha do Cardoso State Park (São Paulo). Not known in trade.

Bibliography. Aleixo & Galetti (1997), Beissinger & Snyder (1992), Bertagnolli (1981), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Descourtiz (1983), Forrester (1993), King (1978/79), Low (1972), Pineschi (1990), Pinto (1938, 1946, 1964), Ribeiro (1920), Ridgely (1981), Scott & Brooke (1985), Sick (1969, 1985, 1993), Sick & Teixeira (1979), Stotz *et al.* (1996), Wege & Long (1995), Whitney (1996), Willis & Oniki (1981).

279. Golden-tailed Parrotlet

Touit surda

French: Toui à queue d'or **German:** Gelbschwanzpapagei **Spanish:** Cotorrita Sorda

Taxonomy. *Psittacus surdus* Kuhl, 1820, Brazil.

NE Brazilian population, if proven racially distinct, must be known as *chryseura* (Swainson, 1820), not *ruficauda* Berla, 1954. Monotypic.

Distribution. NE & E Brazil.

Descriptive notes. 16 cm. Green, brighter on undersides; yellow on forehead and face; scapulars olive brown; rump bluish; flight-feathers dusky brown; lateral tail feathers greenish yellow tipped black. Female tail tipped blackish. Immature undescribed.

Habitat. Lowland evergreen and sand-plain forest, and adjacent lower montane forest, reaching to 900 m.

Food and Feeding. Unripe fruits of *Spondias lutea* and ripe fruits of *Rapanea schwackeana* recorded, also those of a myrtaceous tree.

Breeding. No information. Presumably Sept-Oct at start of rains, like most E Brazil

endemics.

Movements. Some local or seasonal displacements: in Rio de Janeiro state, appears at Cabo Frio, Jun-Sept. and at Majé, Mar; in Ilha Bela State Park, only in "summer".

Status and Conservation. **ENDANGERED.** CITES II. Generally rare and likely to have suffered a major and continuing decline with steady clearance of final vestiges of lowland forest outside of protected areas. Recorded from Murici and Pedra Talhada Biological Reserves (Alagoas), Monte Pascoal National Park (Bahia), Córrego Grande, Sooretama and Augusto Ruschi Biological Reserves (Espírito Santo), Desengano State Park and Itatiaia National Park (Rio de Janeiro), Boracéia Biological Station, Fazenda Intervalos State Reserve, and Ilha Bela, Jacupiranga and Ilha do Cardoso State Parks (São Paulo). Trade appears to be very light.

Bibliography. Beissinger & Snyder (1992), Berla (1954), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Forrester (1993), Gonzaga (1986), King (1978/79), Low (1972), Pineschi (1990), Pinto (1935, 1964), Pinto & Camargo (1961), Ribeiro (1920), Ridgely (1981), Scott & Brooke (1985), Sick (1985, 1993), Sick & Teixeira (1979), Stotz *et al.* (1996), Wege & Long (1995), Whitney (1996).

280. Spot-winged Parrotlet

Touit stictoptera

French: Toui tacheté **German:** Tüpfelpapagei **Spanish:** Cotorrita Alipinta

Taxonomy. *Urochroma stictoptera* P. L. Sclater, 1862, Bogotá, Colombia.

Supposedly separate species listed as "*T. emmae*" was based on adult female of present species. Monotypic.

Distribution. S Colombia, Ecuador and N Peru.

Descriptive notes. 17-18 cm; 71-84 g. Green, paler on underparts; wings dusky brown, with whitish tips to coverts and two outer median coverts orange. Female has green wing-coverts with black bases. Immature similar.

Habitat. Tall humid montane forest at 500-2400 m (chiefly 1050-1700 m) in upper tropical and lower subtropical zone; recorded also from savanna-like habitat and, nearby, in stunted ridge-top forest, and possibly only in poor soil forests in Peru.

Food and Feeding. Fruit and seeds, including mistletoe; reportedly raids maize crops and sometimes feeds in *Ficus* and *Clusia* trees.

Breeding. Very circumstantial evidence for Mar in Ecuador; specimens in Jun and Oct-Nov had undeveloped gonads, and birds were in flocks at these times.

Movements. No evidence of wandering.

Status and Conservation. **VULNERABLE.** CITES II. Uncommon although probably unrecorded. Threatened by habitat destruction within apparently fragmented and disjunct range, especially in Colombia, but exploration of suitable habitat in E Ecuador and NE Peru needed to clarify status. Recorded from Serranía de la Macarena National Park (Colombia), and Cayambe-Coca Ecological Reserve, Sumaco and Cordillera de Cutucú Protection Forests, and Sangay National Park (Ecuador).

Bibliography. Beissinger & Snyder (1992), Blake (1962), Borrero (1958), Butler (1979), Chapman (1917), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Davis (1986), Dugand (1945a, 1945b), Hilty & Brown (1986), Low (1972), O'Neill (1981, 1987), Parker *et al.* (1982), Philipson *et al.* (1951), Ridgely (1980, 1981), Robbins *et al.* (1987), Stotz *et al.* (1996), Wege & Long (1995), Whitney (1996).

Genus *PIONITES* Heine, 1890

281. Black-crowned Parrot

Pionites melanocephala

French: Caique maïpourri **German:** Grünzügelpapagei **Spanish:** Lorito Chirlecrés
Other common names: Black-headed Parrot/Caique

Taxonomy. *Psittacus melanocephalus* Linnaeus, 1758, Mexico: error = Caracas, Venezuela. Forms a parapatric species pair with *P. leucogaster*. Two subspecies recognized.

Subspecies and Distribution.

P. m. melanocephala (Linnaeus, 1758) - SE Colombia to NE Venezuela, the Guianas and Brazil N of Amazon.

P. m. pallida (Berlepsch, 1889) - S Colombia W & E of Andes S to E Ecuador and NE Peru.

Descriptive notes. 23 cm; 130-170 g. Forehead to nape black with rufous-orange band across hindneck; lores to below eye green; face, sides of neck and upper breast yellow; back and wings dull green with dark blue primaries and reddish orange axillaries; lower breast and belly creamy; thighs, flanks and vent apricot yellow; tail above green tipped yellow, below olive-yellow. Immature pale yellow on breast and belly. Race *pallida* has breast and belly whiter, hindneck band paler.

Habitat. Lowland humid tropical *terra firme* forest and seasonally flooded *várzea* forest, second growth and clearings, penetrating in

small numbers up to 1000 m in W of range.

Food and Feeding. Seeds of *Carapa densiflora*, *Hevea benthamiana*, *Guarea grandiflora*, *Pouroma guianensis* and *Micropholis mensalis*, pulp of *Dialium guianensis*, *Euterpe precatoria*, *Micropholis melinoneana* and *Cynometra hostmanniana*, seeds and pulp of *Clusia grandiflora*, flowers of *Eschweilera* and *Inga laterifolia*, and leaves of *Sterculia excelsa*. In dry season favours flowers of *Symphonia globulifera* and the *Norantea* liana.

Breeding. Apr-May in Venezuela and Colombia; Oct-Nov in Surinam; Dec-Feb in French Guiana. Nest is hole in tree. Eggs probably 2.

Movements. Nomadic in French Guiana in response to food availability.

Status and Conservation. Not globally threatened. CITES II. Generally common throughout range; vast areas of habitat remain. Little persecuted for international pet trade, but highly prized in Venezuela, where very common in captivity.

Bibliography. Desenne (1994), Desenne & Strahl (1991, 1994), Dugand & Borrero (1948), Friedmann (1948b), Haffer (1977b), Haverschmidt & Mees (1994), Hilty & Brown (1986), Low (1972), McLoughlin (1983), Meyer de Schauensee & Phelps (1978), Niceforo & Olivares (1966), Novaes (1981), O'Neill (1981), O'Neill & Pearson (1974), Polimore (1936), Pinto (1964), Ridgely (1981), Sick (1985, 1993), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Traylor (1958), Whitney (1996).

282. White-bellied Parrot

Pionites leucogaster

French: Caique à ventre blanc **German:** Rostkappenpapagei **Spanish:** Lorito Rubio
Other common names: White-bellied Caique

Taxonomy. *Psittacus leucogaster* Kuhl, 1820, Brazil.

Forms a parapatric species pair with *P. melanocephala*. Three subspecies recognized.

Subspecies and Distribution.

P. l. xanthomeria (P. L. Slater, 1858) - E Peru and N Bolivia to W Brazil S of Amazon.

P. l. xanthurus Todd, 1925 - Brazil S of Amazon from R Purús and R Jurua to R Madeira.

P. l. leucogaster (Kuhl, 1820) - N Brazil from R Madeira to Maranhão.

Descriptive notes. 23 cm; mean 155 g. Forehead to nape orange; face, sides of neck and upper breast yellow; back and wings dull green with dark blue primaries and reddish orange axillaries; lower breast and belly white; flanks, thighs, rump and tail bright green; vent yellow. Immature has crown and nape brownish. Race *xanthurus* replaces bright green (including tail) with yellow (some intermediates); *xanthomeria* like *xanthurus* but with green tail.

Habitat. Lowland humid tropical *terra firme* forest, more particularly seasonally flooded *várzea* forest along watercourses, and possibly prefers margins and openings to continuous forest; penetrates drier forests in S of range, but not so common.

Food and Feeding. No specific information.

Breeding. Jan in E of range, where one nest found was in hollow in tree 30 m up, containing 2 eggs.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Common in most of range and in parts of E Peru abundant, but suffering from habitat destruction in the E and SW, and possibly extinct in Santa Cruz, Bolivia, as a consequence. Present in Manu National Park, Peru, where density reaches 6 pairs/km². From 1980 to 1983 2475 birds were exported from Bolivia, but all trade stopped in 1984.

Bibliography. Allen (1995), Fry (1970), Haffer (1977b), Inskipp *et al.* (1988), Low (1972), Novaes (1981), O'Neill (1981), Parker *et al.* (1982), Pinto (1964), Polimore (1936), Remsen *et al.* (1986), Ridgely (1981), Sick (1985, 1993), Stotz *et al.* (1996), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Wheatley (1994), Whitney (1996).

Genus *PIONOPSITTA* Bonaparte, 1854

283. Vulturine Parrot

Pionopsitta vulturina

French: Caique vautourin **German:** Kahlkopfpapagei **Spanish:** Lorito Vulturino

Taxonomy. *Psittacus vulturinus* Kuhl, 1820, Brazil.

Commonly placed in genus *Gypopsitta*, on basis of bare head in adults, but this character is probably of little or no taxonomic significance; in other respects species clearly belongs in *Pionopsitta* and indeed may form a superspecies or parapatric species trio with *P. barrabandi* and *P. caica*. Monotypic.

Distribution. N Brazil S of Amazon from R Madeira E to Maranhão.

Descriptive notes. 23 cm; 138-165 g. Generally green; head bare, covered in bristles that match skin, with lores and base of lower mandible yellowish flesh, rest black; complete (feathered) collar yellow, bordered black on nape and sides of neck; breast olive yellow, lightly edged black; belly with some blue edges; lower thighs yellow; shoulder reddish orange; primaries black margined green; carpal edge and underwing-coverts red; tail with much yellow below, tipped dull blue above. Immature has feathered green head, yellowish around lores and eye; lacks yellow collar and black bordering.

Habitat. Occupies both dryland *terra firme* and seasonally flooded (*várzea*) forest.

Food and Feeding. No specific information. The bare head may be an adaptation to a particular large fruit whose juice mats feathers.

Breeding. No information.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Uncommon within relatively small range, which is rapidly being cleared of forest in the E, where new forest reserves are sorely needed; present in Amazonia National Park in W of range. There is no known pressure from trade.

Bibliography. Forrester (1993), Low (1972), Olrog (1968), Pinto (1964), Ridgely (1981), Ruschi (1979), Sick (1985, 1993), Stone (1929), Stotz *et al.* (1996), Wheatley (1994), Whitney (1996).

284. Brown-hooded Parrot

Pionopsitta haematotis

French: Caique à capuchon **German:** Grauwangenpapagei **Spanish:** Lorito Encapuchado

Taxonomy. *Pionus haematotis* P. L. Slater and Salvin, 1860, Vera Paz, Guatemala.

Forms a parapatric species pair with *P. pulchra*, which has been regarded as conspecific. Two subspecies recognized.

Subspecies and Distribution.

P. h. haematotis (P. L. Slater & Salvin, 1860) - SE Mexico through N Guatemala to W Panama.

P. h. coccinillarioris (Lawrence, 1862) - E Panama and NW Colombia.

Descriptive notes. 21-23 cm; 145-150 g. Reddish brown crown and ear-coverts with pinkish red auricular patch, with white nares and orbital ring; nape and breast dull olive yellow; flanks and axillaries red; rest of body green except blue on edge of wing, flight-feathers blackish blue, tail tipped blue with dull red basally on outer feathers. Immature has paler head with no auricular patch, breast greener. Race *coccinillarioris* has some pinkish red, sometimes forming a full band, below dark throat.

Habitat. Humid evergreen and cloud forest and borders, mature second growth, in lowlands and lower subtropical zone, regularly ranging up to 1200 m, perhaps less frequently up to 1900 m.

Food and Feeding. Fruits and seeds of various trees and epiphytes, e.g. *Ficus*, *Heliconia*, *Croton*, *Erythrina*, plus green leaves of certain mistletoes.

Breeding. Breeding condition birds taken in Feb in Mexico, May-Jul in Guatemala, and Aug in Panama. Nest in hole in tree. No further information.

Movements. Birds found above 1200 m thought perhaps to be seasonal migrants, but in Costa Rica breeding may occur on slopes up to 1600 m with a subsequent descent to lowlands.

Status and Conservation. Not globally threatened. CITES II. Although there must have been a decline from habitat loss, this bird is fairly common over much of range and suffers very little persecution even locally from trapping, and even though they are reported, perhaps rather surprisingly, to attack corn crops in Guatemala.

Bibliography. Binford (1989), Blake (1958), Clinton-Eitner *et al.* (1994), González-García (1993), Haffer (1975), Hilty & Brown (1986), Howell & Webb (1995a), Land (1970), Loetscher (1941), Low (1972), Monroe (1968), Paynter (1955), Ridgely (1981), Ridgely & Gwynne (1989), Russell (1964), Slud (1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Thompson (1962), Wetmore (1944, 1968), Whitney (1996).

285. Rose-faced Parrot

Pionopsitta pulchra

French: Caique à joues roses **German:** Rosenwangenpapagei **Spanish:** Lorito Carirrosado
Other common names: Beautiful Parrot

Taxonomy. *Pionopsitta pulchra* Berlepsch, 1897. San José, Río Dagua, Colombia. Forms a parapatric species pair with *P. haematotis*, with which considered conspecific in past. Monotypic.

Distribution. Lowlands and foothills of W Colombia and NW Ecuador.

Descriptive notes. 23 cm. Like *P. haematotis* but large pinky rose facial area extending from lores, over eye to side of neck, paler on cheeks; also bend of wing orange and yellow, and no red on flanks and axillaries. Immature has rosy pink restricted mostly to ear-coverts, rest of face greenish.

Habitat. Wet forest, tall second growth, plantations and clearings with scattered trees, usually below 1200 m but locally to 2100 m.

Food and Feeding. Virtually unknown. Small fruit and cultivated bananas recorded.

Breeding. Jan-Mar in N of range, Nov-Dec in C. No further information.

Movements. Apparent local increases in numbers may be seasonal, but no clear information.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Uncommon and local, but sometimes fairly numerous and capable of doing damage to banana

crops. Forest remains within its range, but under intensifying logging pressure, notably in Ecuador. Apparently not traded.

Bibliography. Butler (1979), Haffer (1967, 1975), Hilty & Brown (1986), Kirwan & Marlow (1996), Low (1972), Marín & Carrión (1991), Olivares (1957), Ridgely (1981), Stotz *et al.* (1996), Taylor (1995a), Wheatley (1994), Whitney (1996), Williams *et al.* (1996).

286. Orange-cheeked Parrot

Pionopsitta barrabandi

French: Caique de Barraband **German:** Goldwangenpapagei **Spanish:** Lorito Carinaranja
Other common names: Barraband's Parrot

Taxonomy. *Psittacus Barrabandi* Kuhl, 1820. Brazil.

May form superspecies or parapatric species trio with *P. caica* and *P. vulturina*. Two subspecies recognized.

Subspecies and Distribution.

P. b. barrabandi (Kuhl, 1820) - SW Colombia and S Venezuela to Brazil N of Amazon (E to R Negro). *P. b. aurantiigena* Gyldenstolpe, 1951 - E Ecuador, E Peru and N Bolivia to Brazil S of Amazon (E to R Madeira).

Descriptive notes. 25 cm; 165-190 g (mean also given as 140 g). Head black circumscribing large orange yellow malar patch and white bare orbital ring; throat and upper breast olive yellow; rest of body green, but with shoulder orange yellow, carpal edge and underwing-coverts red, primaries blackish, thighs yellow, tail tipped dull blue. Immature has head brown and olive, less orange and red in wing. Race *aurantiigena* has richer orange malar patch, shoulder and thighs.

Habitat. Like *P. caica* a bird of primary lowland *terra firme* forest, but sometimes also in seasonally flooded *várzea* forest, and sandy-

belt woodland; ranges up to only 500 m.

Food and Feeding. Seeds and fruits: of six food-plants, three were Moraceae (*Ficus*, *Pourouma* and *Pseudolmedia*), two Leguminosae (*Mimosa* and *Pithecellobium*), and one Olacaceae (*Heisteria*); figs, e.g. of *Ficus spheophylla* and another with larger fruit, clearly important. Seen biting leaf galls on *Pithecellobium* trees, presumably for wasp larvae.

Breeding. Probably Sept-Oct in E of range, based on immatures in Feb. No further data.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Generally uncommon and local, but occasionally frequent to numerous in W parts of range, e.g. N Bolivia, this possibly related to scarcity of *Pionus menstruus* and *Amazona* species in the region. Present in Manu National Park, Peru, where density reaches 0.5 pairs/km². Habitat for this species is still very extensive and intact, despite encroachments from E and S, and trade is minimal.

Bibliography. Desenne & Strahl (1991, 1994), Gyldenstolpe (1951), Hilty & Brown (1986), Inskipp *et al.* (1988), Low (1972), Meyer de Schauensee & Phelps (1978), O'Neill (1981), Parker & Remsen (1987), Parker, Castillo *et al.* (1991), Parker, Parker & Plenge (1982), Phelps & Phelps (1958), Pinto (1964), Poulsen (1992), Remsen & Ridgely (1980), Ridgely (1981), Roth (1983), Sick (1985, 1993), Stotz *et al.* (1996), Terborgh *et al.* (1990), Whitney (1996).

287. Saffron-headed Parrot

Pionopsitta pyrrhila

French: Caique de Bonaparte **German:** Goldkopfpapagei **Spanish:** Lorito Cabecigualdo

Taxonomy. *Psittacula pyrrhila* Bonaparte, 1853, Río Hacha, Santa Marta, Colombia. Once considered sufficiently distinct to warrant its own genus *Pyrrhila*. Monotypic.

Distribution. E Panama through N & C Colombia to NW Venezuela.

Descriptive notes. 24 cm. Head including nape, sides of neck and chin yellow, stained red around and behind eyes, bare orbital ring white circled by brown extending onto lores and nares; breast olive, extending to form full collar; rest of body green, with yellow shoulders, red carpals and blackish primaries, red on flanks and underwing, plus yellow lower thighs and dusky blue tips to tail. Immature has green head, shoulders and carpal edge.

Habitat. Humid and wet forest, tall second growth and borders, in lowlands and foothills, regularly to c. 900 m, perhaps only seasonally into cloud forest up to 1650 m.

Food and Feeding. No information.

Breeding. Mar-Jun in Colombia. No further information available.

Movements. Higher elevation records may be seasonal in nature, and records from Pacific coast of Colombia as far S as Buenaventura may refer to nomads.

Status and Conservation. Not globally threatened. CITES II. Apparently uncommon over much of its range, and never very numerous. Although described as still well represented in several parts of Colombia, other reports suggest that it is now very rare throughout its range, with less than 10,000 birds remaining. Considerable habitat loss has occurred both historically and in modern times, and numbers must have declined over several centuries, apparently now gone from C Andes and from near Bogotá; habitat loss in Venezuela is a serious threat. Present on Cerro Pirre in Darién National Park, Panama. Apparently very little traded, even in recent times in Venezuela.

Bibliography. Delgado (1985a), Desenne & Strahl (1991, 1994), Haffer (1975), Hilty & Brown (1986), Low (1972), Meyer de Schauensee & Phelps (1978), Olivares (1969), Olrog (1968), Ridgely (1981), Ridgely & Gwynne (1989), Robbins *et al.* (1985), Stotz *et al.* (1996), Wetmore (1968), Wheatley (1994), Whitney (1996).

288. Caica Parrot

Pionopsitta caica

French: Caique à tête noire **German:** Kappenpapagei **Spanish:** Lorito Caica

Taxonomy. *Psittacus Caica* Latham, 1790, Cayenne.

May form a superspecies or parapatric species trio with *P. barrabandi* and *P. vulturina*. Monotypic.

Distribution. E Venezuela, the Guianas and N Brazil S to Amazon.

Descriptive notes. 23 cm; 121-143 g. Head brownish black, with bare orbital ring grey; fulvous collar with dark feather edges, producing scaled effect; throat and upper breast olive brown; rest of body green, with dull blue primary coverts, primaries blackish, tail tipped dull blue. Immature is much greener on head.

Habitat. Tall, primary *terra firme* forest and edge to 1100 m, rarely penetrating flooded forest or secondary growth.

Food and Feeding. Very few specific data. Seeds of *Dracoides sagotianum*, *Protium*, *Brosium*; once seen feeding on small dark red fruits.

Breeding. Nov-Jan in French Guiana. Nest in

hole in tree 10 m up (only record). No further information.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Nowhere plentiful. Scarce throughout Surinam, very local in Venezuela, but little affected either by habitat loss or by trade. Common in interior French Guiana.

Bibliography. Desenne & Strahl (1991, 1994), Haffer (1970), Haverschmidt & Mees (1994), Low (1972), Meyer de Schauensee & Phelps (1978), Olrog (1968), Phelps & Phelps (1958), Pinto (1964), Ridgely (1981), Sick (1985, 1993), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992), Wheatley (1994), Whitney (1996).

289. Pileated Parrot

Pionopsitta pileata

French: Caique mitré **German:** Scharlachkopfpapagei **Spanish:** Lorito Pileado
Other common names: Red-capped Parrot

Taxonomy. *Psittacus pileatus* Scopoli, 1769, south-eastern Brazil. Monotypic.

Distribution. SE Brazil, E Paraguay and N Argentina.

Descriptive notes. 22 cm; 98-120 g. Forehead, crown and lores to upper ear-coverts red, though extent of this rather variable; rest of body green, but becoming yellowish on abdomen, and with dull blue in primary coverts, primaries, edges to outer wing-coverts and tail feathers, and tail tips. Female lacks red on head, but has blue suffusion on forehead and breast. Immature male has reduced red on head, female reduced blue on wings.

Habitat. Mainly humid foothill forest up to 1500 m in N of range, extending into *Araucaria*-dominated and lowland formations in S, including partially cleared areas.

Food and Feeding. Virtually unknown. Fruits of *Podocarpus* and "cambuf", seeds of *Solanum mauricianum*, bark of *Eucalyptus*.

Breeding. Apparently Nov. Nest in hole in tree. Eggs 2, but 3-4 in captivity where incubation, by female only, lasted 24 days and nestling period 52-54 days.

Movements. Some movements between coastal and interior areas occur, with presence in Oct in Amambay, Paraguay; strikingly nomadic at Intervalles State Park, São Paulo.

Status and Conservation. Not globally threatened. CITES I. Currently considered near-threatened. Much reduced by extensive habitat

loss throughout range, but still persists in reasonable numbers where cover extensive, notably Paraná and adjacent states, Brazil; it remains common in the Alto Paraná region, Paraguay. There appear to be no recent records from Corrientes, Argentina, but still common in Misiones.

Bibliography. Aleixo & Galetti (1997), Belton (1984), Bertagnolio (1981), Brooks *et al.* (1993), Canevari *et al.* (1991), Chebez (1992), Contreras *et al.* (1990), Eckelberry (1965), Guix (1995), Harrison (1984), Hayes (1995), Low (1972), Lowen *et al.* (1996), Nores & Yzurieta (1994), de la Peña (1988), Pinto (1964), Pizo *et al.* (1995), Ridgely (1981), Robiller & Trogisch (1985a), do Rosário (1996), de Ruiter (1994b), Scherer-Neto & Müller (1983), Sick (1985, 1993), Smith (1977b), Stotz *et al.* (1996), Whitney (1996), Willis & Oniki (1981).

Genus *HAPALOPSITTACA* Ridgway, 1912

290. Black-winged Parrot

Hapalopsittaca melanotis

French: Caique à ailes noires **German:** Schwarzflügelpapagei **Spanish:** Lorito Alinegro
Other common names: Black-eared Parrot

Taxonomy. *Pionus melanotis* Lafresnaye, 1847, Bolivia.

Two subspecies recognized.

Subspecies and Distribution.

H. m. peruviana (Carriker, 1932) - C to S Peru.

H. m. melanotis (Lafresnaye, 1847) - CW Bolivia.

Descriptive notes. 24 cm. Green, more yellowish on underparts; frontal band and lores blue, crown tinged blue-grey; narrow bare skin round eye dark, surrounded by flesh-coloured feathering; ear-coverts black; unbroken but indistinct collar blue-grey; much black on folded wing, primaries mostly blue; tail tipped blackish blue. Immature undescribed. Race *peruviana* has ear-coverts buff, reduced blue collar.

Habitat. Patches of humid montane evergreen forest, cloud and elfin forest between 1740 and 3450 m, sometimes at the edge of cultivated land.

Food and Feeding. Berries taken in treetops, with a strong preference for mistletoes of the genus *Gaiadendron*.

Breeding. No information.

Movements. May be seasonal at higher altitudes; groups of up to 50 observed wandering between wooded patches, searching for fruiting mistletoes.

Status and Conservation. Not globally threatened. CITES II. A BirdLife "restricted-range" species. Locally common, sometimes occurring in fairly large flocks, but evidently scarcer in Peru than Bolivia.

Bibliography. Bond & Meyer de Schauensee (1943), Fjeldså & Krabbe (1990), Low (1972), O'Neill (1981), Olrog (1968), Parker *et al.* (1982), Remsen & T aylor (1989), Ridgely (1981), Stotz *et al.* (1996), Wheatley (1994), Whitney (1996), Whitney *et al.* (1994).

291. Rusty-faced Parrot

Hapalopsittaca amazonina

French: Caique à face rouge **German:** Zwergamazona **Spanish:** Lorito Amazonino

Taxonomy. *Psittacus amazoninus* Des Murs, 1845, Bogotá.

Forms superspecies with *H. fuertesi* and *H. pyrrhops*, and all three have commonly been considered conspecific. Three subspecies recognized.

Subspecies and Distribution.

H. a. velezi Graves & Uribe Restrepo, 1989 - C Andes of Colombia.

H. a. amazonina (Des Murs, 1845) - E Andes of Colombia.

H. a. theresae (Hellmayr, 1915) - extreme E Colombia and NW Venezuela.

Descriptive notes. 23 cm; 97-115 g. Forehead and crown dull orange-red, lores yellow, extending below eye, base of lower mandible to chin orange-red, ear-coverts brownish red with yellow streaks radiating towards nape and down onto sides of neck; rest of upperparts green except for strong red shoulder patch, blue secondary coverts, dark primaries; breast buffy olive, rest of underparts grass green; tail dark red with blue-black to violet-blue tip. Immature has yellow streaks reduced, face duller red. Race *theresae* darker green above, with red on head

vertical displacements.

Status and Conservation. **ENDANGERED.** CITES II. A BirdLife "restricted-range" species. Generally rare throughout its range; the only site at which it was ever recorded as common, El Roble in Colombia (nominally *amazonina*) has long since been deforested, and total populations of all three races are likely to be low. Habitat clearance in Venezuela is proceeding rapidly, and two main protected areas where it occurs, El Tamá and Sierra Nevada National Parks, are themselves threatened; the species is also recorded from Páramos de Batallón y La Negra National Park (Venezuela) and Chingaza, Puracé and Cueva de los Guácharos National Parks (Colombia). Virtually unknown in trade.

Bibliography. Beissinger & Snyder (1992), Brockner (1997), Butler (1979), Carriker (1955), Chapman (1917), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Desenne & Strahl (1991), Fjeldsá & Krabbe (1990), Graves & Uribe (1989), Hilty & Brown (1986), Low (1972), Meyer de Schauensee & Phelps (1978), O'Neill (1981), Phelps & Phelps (1958), Ridgely (1981), Ridgely & Gaulin (1980), Stotz *et al.* (1996), Wege & Long (1995), Whitney (1996).

292. Indigo-winged Parrot

Hapalopsittaca fuertesi

French: Caïque de Fuertes

German: Fuertespapagei

Spanish: Lorito de Fuertes

Other common names: Fuertes's Parrot

Taxonomy. *Pionopsitta fuertesi* Chapman, 1912, Laguneta, Cauca, Colombia.

Forms superspecies with *H. amazonina* and *H. pyrrhops*, and all three have commonly been considered conspecific. Monotypic.

Distribution. C Andes of Colombia.

Descriptive notes. 24 cm. Very like *H. amazonina*, but red on face confined to area over bill and no yellow streaking; forehead and upper cheeks dull yellow; mid- to hindcrown blue; belly with dull red patch.

Habitat. Wet, epiphyte-rich temperate cloud forest including oaks *Quercus* at 2610-3490 m, the majority of records being at 2900-3150 m.

Food and Feeding. No information, but likely to share preference for mistletoes shown by congeners.

Breeding. No information.

Movements. Unknown, but altitudinal dis-

placements probably occur.

Status and Conservation. **CRITICALLY ENDANGERED.** CITES II. A BirdLife "restricted-range" species. Extremely rare, and only known from Alto Quindío Acaime and Cañón del Quindío Natural Reserves, where the largest group seen was 25; no record since 1992. Extensive deforestation coupled with competition from *H. amazonina velezi* may have caused it to have become so strictly confined. It has not been traded.

Bibliography. Beissinger & Snyder (1992), Chapman (1912, 1917), Collar (1996), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Fjeldsá & Krabbe (1990), Graves & Uribe (1989), Hilty & Brown (1986), King (1978/79), Low (1972), Olrog (1968), Renjifo (1991), Ridgely (1981), Stotz *et al.* (1996), Wege & Long (1995), Wheatley (1994), Whitney (1996).

293. Red-faced Parrot

Hapalopsittaca pyrrhops

French: Caïque de Salvin

German: Salvinpapagei

Spanish: Lorito Ecuatoriano

Taxonomy. *Pionopsitta pyrrhops* Salvin, 1876, Santa Rita and San Lucas, Ecuador.

Forms superspecies with *H. amazonina* and *H. fuertesi*, and all three have commonly been considered conspecific. Monotypic.

Distribution. SW Ecuador to NW Peru.

Descriptive notes. 22 cm. Very like *H. amazonina* but entire area around bill orange red, extending in line above and behind eye; crown otherwise green, tinged blue; breast less olive; less blue on wing-coverts; tail dark blue, green at base; variable red patch on belly in some birds. Immature not known.

Habitat. Very wet upper montane cloud forest, forest patches and shrubbery at the páramo ecotone, 2500-3500 m.

Food and Feeding. *Miconia* fruits, *Viburnum* berries, *Weinmannia* shoots, flowers and seeds, *Clethra* flowers and pods, and parts of ericaceous trees *Cavendishia* and *Disterigma*.

Breeding. Oct-Jan, possibly also Aug. Nest in cavity in tree. Eggs 2, possibly sometimes 3.

Movements. Some seasonal or irregular displacements, possibly mainly altitudinal in nature, occur.

Status and Conservation. **ENDANGERED.** CITES II. A BirdLife "restricted-range" species. Very uncommon and local in Ecuador, where forest clearance almost total within its elevational range in

the Chilla Mountains; and rare (one locality) in Peru. Occurs at least seasonally in Sangay and Podocarpus National Parks, Cajas National Recreation Area and the adjacent Río Mazan Reserve, Ecuador.

Bibliography. Beissinger & Snyder (1992), Bloch *et al.* (1991), Chapman (1926), Collar (1996), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Fjeldsá & Krabbe (1990), Flanagan & Galvez (1996), King (1989), Low (1972), Parker *et al.* (1985), Rasmussen *et al.* (1996), Ridgely (1980, 1981), Stotz *et al.* (1996), Toyne (1996), Toyne & Flanagan (1996), Toyne *et al.* (1995), Wege & Long (1995), Whitney (1996), Williams & Tobias (1994).

Genus *GRAYDIDASCALUS* Bonaparte, 1854

294. Short-tailed Parrot

Graydidascalus brachyurus

French: Caïque à queue courte

German: Kurzschwanzpapagei

Spanish: Lorito Colicorto

Taxonomy. *Psittacus brachyurus* Kuhl, 1820, Cayenne; error = upper Amazonia. Monotypic.

Distribution. SE Colombia, E Ecuador and E Peru through Amazon basin to NE French Guiana and Brazil N of Amazon Delta.

Descriptive notes. 24 cm; 188-233 g. Green, paler and more yellowish on underparts and uppertail-coverts; primaries darker green; wing-coverts edged yellow; short tail basally banded red on outer feathers; bill light green to olivaceous to dark grey; eye orange-red, with indistinct dark line in front and behind. Immature lacks red in tail.

Habitat. Seasonally flooded *várzea* forest and secondary growth in other swampy habitats on islands and in floodplains along larger rivers, edges of mangroves at coasts, penetrating man-made habitats at times (e.g. cultivations, with a record of a roost tree in a town street); low-

lands to 400 m.

Food and Feeding. Fruits including *Ficus*, cultivated guava (*Psidium guajava*), seeds, nuts, berries, in particular *Cecropia* catkins; tubers found in one stomach.

Breeding. Birds with partly developed gonads in Sept, E Brazil. No other information.

Movements. May be seasonal in some areas, this perhaps geared to flooding of habitat; in Loreto, E Peru, present Jun-Aug.

Status and Conservation. Not globally threatened. CITES II. Common, sometimes locally abundant, but becoming scarcer in upper reaches of rivers, presumably owing to restricted habitat. Little traded.

Bibliography. Gyldestolpe (1951), Hilty & Brown (1986), Low (1972), Novaes (1974), O'Neill (1981), O'Neill & Pearson (1974), Pinto (1964), Ridgely (1980, 1981), Schubart *et al.* (1965), Sick (1985, 1993), Smith (1978a), Stotz *et al.* (1996), Tostain *et al.* (1992), Wheatley (1994), Whitney (1996).

Genus *PIONUS* Wagler, 1832

295. Blue-headed Parrot

Pionus menstruus

French: Pioné à tête bleue

German: Schwarzohrpapagei

Spanish: Loro Cabeciazul

Other common names: Red-vented Parrot

Taxonomy. *Psittacus menstruus* Linnaeus, 1766, Surinam.

Three subspecies normally recognized.

Subspecies and Distribution.

P. m. rubrigularis Cabanis, 1881 - NE Costa Rica to N & W Colombia and W Ecuador.

P. m. menstruus (Linnaeus, 1766) - E Colombia, E Ecuador, E Peru and N Bolivia E to Venezuela, Trinidad and the Guianas, and through Amazonia to NE Brazil.

P. m. reichenowi (Heine, 1884) - E Brazil.

Descriptive notes. 24-28 cm; 209-295 g. Blue head and breast with blackish ear-coverts and some slight red flecking on throat; underparts green with some blue edging to feathers; undertail-coverts and bases of tail feathers red; remainder largely green. Immature largely without blue on head, and undertail-coverts yellowish green. Race *reichenowi* darker blue on head, with more blue in green plumage, no red on throat, paler bill, and strong golden wash on lesser and median upperwing-coverts; race *rubrigularis* has duller blue head and more obvious red on throat.

Habitat. Deciduous woodland including *cerrado*, humid and wet forest, mature second growth, seasonally flooded (*várzea*) and gallery forest, plantations, clearings and semi-open areas with scattered trees including *Mauritia* palm stands, ranging locally up to 1400 m.

Food and Feeding. Seeds of *Albizia*, *Anacardium*, *Caraipa*, *Dialium*, *Hevea*, *Hura*, *Clusia*, *Ocotea*, *Couroutaria*, *Inga*, *Brosimum*, *Tectona*, *Micropholis*, fruit of *Tetragastris*, *Inga*, *Ficus*, *Euterpe*,

sugary flowers of *Noranthea* liana, also of *Erythrina*; *Goupia*, *Pseudolmedia*, *Psidium*, *Mangifera* and *Pourouma* also mentioned. On Trinidad takes corn (*Zea mays*).

Breeding. Jan-May in Panama; Feb-Apr in Ecuador, Colombia and Venezuela; Mar and Oct on Trinidad; Oct and Jan-Feb in the Guianas; Jun-Jul, sometimes extended possibly through re-nesting into Nov in Mato Grosso. Nest in palm stub or hole of living or dead tree, in trunk or branch greater than 40 cm in diameter, 8-30 m from ground. Eggs 4; incubation by female. In captivity, incubation period lasts 24-29 days, with nestling period 55-60 days.

Movements. Movements occur in some regions, associated with new availability of food. Birds immigrate to islands off Panama after breeding, Jun. In some years in Surinam they arrive at the coast in Jul-Aug. and large nomadic flocks form in littoral forests in French Guiana.

Status and Conservation. Not globally threatened. CITES II. One of the most numerous parrot species in South America, common throughout its range in a variety of lowland wooded habitats. Commonly visit croplands and despoil maize and rice. Judged to have invaded Costa Rica this century, where range expanding rapidly on Pacific slope. Trade pressure relatively slight in spite of numbers of birds in wild.

Bibliography. Desenne (1994), Desenne & Strahl (1991, 1994), Eisenmann (1952), Fernández-Badillo *et al.* (1994), ffrench (1991), Friedmann (1948b), Galetti & Rodrigues (1992), Haffer & Fitzpatrick (1985), Haverschmidt & Mees (1994), Hilty & Brown (1986), Howell & Webb (1995a), Ingels (1978), Lantermann (1983), Lantermann & Wozniak (1986), Low (1972), Lowry (1991), Meyer de Schauensee & Phelps (1978), O'Neill (1981), Parker *et al.* (1982), Ridgely (1981), Ridgely & Gwynne (1989), da Rocha *et al.* (1988), Sick (1985, 1993), Slud (1964), Snyder (1966), Stiles & Skutch (1989), Stotz *et al.* (1996), Terborgh *et al.* (1984), Tostain *et al.* (1992), Toyne & Jeffcote (1994), Tyler (1979), Wetmore (1957, 1968), Whitney (1996).

296. Red-billed Parrot

Pionus sordidus

French: Pionne à bec rouge **German:** Duenenkopfpapagei **Spanish:** Loro Piquirrojo

Taxonomy. *Psittacus sordidus* Linnaeus, 1758, Mexico; error = Venezuela. Six subspecies recognized.

Subspecies and Distribution.

P. s. antelius Todd, 1947 - NE Venezuela.

P. s. sordidus (Linnaeus, 1758) - N Venezuela.

P. s. ponsi Aveledo & Ginés, 1950 - NW Venezuela W to Santa Marta foothills in N Colombia.

P. s. saturatus Todd, 1915 - Santa Marta massif, N Colombia.

P. s. corallinus Bonaparte, 1854 - E Andes of Colombia S through E Ecuador and E Peru to N Bolivia.

P. s. mindoensis Chapman, 1925 - W Ecuador.

Descriptive notes. 28 cm; 272 g. Entire head dull green heavily edged dull blue; bare orbital ring greyish; bill red; upper breast dull blue, with blue scaling on green below, shading to pink-tinged buff-olive on belly; back, wings and tail olive green, latter with blue outer feathers; undertail-coverts and base of tail dull red. Immature green on head and breast, undertail-coverts yellowish green. Race *antelius* paler with little blue on breast; *saturatus* darker and *ponsi* darker still; *corallinus* larger and greener, mantle and back tinged grey and blue; *mindoensis* like *corallinus* but yellower.

Habitat. Humid and wet submontane and low-

land evergreen and semi-deciduous forest, cloud forest and gallery woodland, forest borders, secondary growth, coffee plantations and adjacent clearings, mostly at 500-1500 m, but range 100-2400 m.

Food and Feeding. No specific information; fruits and blossoms mentioned.

Breeding. Feb-Apr in Colombia; Apr in Venezuela; Jan-May in Ecuador; Oct in Bolivia. Nest in hole in tree, in one case 6 m from ground, once in 4 m high rotten stump. In captivity 3 eggs, and 3 nestlings recorded in wild; incubation lasts c. 27 days, nestling period 12 weeks.

Movements. Local movements occur in dry season at Rancho Grande, N Venezuela, but only when little wind, suggesting bird poorly adapted for long-distance daily displacements.

Status and Conservation. Not globally threatened. CITES II. Fairly common in most of range, perhaps less numerous in W Ecuador but one of commonest parrots at 2000 m in La Paz, N Bolivia. Forest clearance in Venezuela and Colombia will have caused long-term local declines and all three races in Venezuela are under pressure, and race *antelius* not found in recent survey of its much cleared habitat. Generally, however, the species persists in moderately disturbed habitat. Little traded anywhere.

Bibliography. Bond & Meyer de Schauensee (1943), Butler (1979), Desenne & Strahl (1991, 1994), Fernández-Badillo *et al.* (1994), Fjeldsá & Krabbe (1990), Harrison & Holyoak (1970), Hilty & Brown (1986), Inskipp *et al.* (1988), Lentino & Portas (1994), Low (1972), Meyer de Schauensee & Phelps (1978), Niethammer (1953), O'Neill (1981), Parker *et al.* (1982), Remsen & Traylor (1989), Ridgely (1981), Stoodley (1978a), Stotz *et al.* (1996), Toyne & Jeffcote (1994), Whitney (1996).

297. Scaly-headed Parrot

Pionus maximiliani

French: Pionne de Maximilien **German:** Maximilienpapagei **Spanish:** Loro Choclero

Taxonomy. *Psittacus Maximiliani* Kuhl, 1820, Viçosa on the Rio Peruhype, south of Caravellas, Bahia. Four subspecies recognized.

Subspecies and Distribution.

P. m. maximiliani (Kuhl, 1820) - NE & CE Brazil.

P. m. siy Souancé, 1856 - SE Bolivia, Paraguay, CW & CS Brazil and N Argentina.

P. m. lacerus (Heine, 1884) - NW Argentina in Tucumán, E Catamarca and S Salta.

P. m. melanoblepharus Miranda-Ribeiro, 1920 - SE Brazil, E Paraguay and N Argentina in Misiones.

Descriptive notes. 25-29 cm; 233-293 g. Forehead and mid-crown blackish brown offsetting white half-rings above and below eye, rest of head, nape and upper back dark greenish bronze with dark edging to feathers giving scaled effect, but with lower back and wings dull green with less intense edging; throat and upper breast dull blue shading into yellowish green; undertail-coverts and tail red basally with blue outer and green central feathers. Immature has paler green head, less blue on

breast. Race *melanoblepharus* larger and darker green with darker blue breast and dark orbital skin; *siy* like *melanoblepharus* with reddish purple chin and throat, and white orbital skin; *lacerus* like *siy* but larger with more intense and extensive blue on breast.

Habitat. Evergreen and semideciduous forest and open scrub woodland, favouring deciduous and gallery formations in the N and W of range such as *caatinga* and Chaco, and more humid ones in SE, including *Araucaria* forest; disturbed areas with scattered groves; regularly up to 1500 m in Brazil and 2000 m in W Argentina.

Food and Feeding. In one forest, 38 plant species from 18 families, with legumes (Fabaceae, notably *Erythrina*, Mimosaceae, notably *Inga* and *Piptadenia*, and Caesalpinaceae, notably *Copaifera*) comprising 41% of feeding bouts, supported by Euphorbiaceae, notably *Croton* and *Pachystroma*; seeds made up 70% of the diet, flowers 20%, corn 8% and fruit pulp 2%. Outside this study, figs and *Araucaria* nuts only specific foods recorded.

Breeding. Oct in Paraguay; Nov in São Paulo. Nest a hole in tree. In captivity: 4-5 eggs; nestling period of 9 weeks.

Movements. Resident.

Status and Conservation. Not globally threatened. CITES II. Although relatively infrequent in N reaches of range, common from Bahia southwards, reaching high densities in certain areas of São Paulo state. Patchily common in Paraguay and Argentina. Some reduction in numbers in SE Brazil from habitat loss. Traded in probably unsustainable volume out of Argentina in mid-1980's, with 67,851 birds exported in period 1981-1990, of which 25,596 in 1985 alone. Despite general ban in Argentina in 1986 this species continued to be traded in thousands, though on a steadily diminishing scale.

Bibliography. Anon. (1993), Belton (1984), Canevari *et al.* (1991), Chebez (1992), Contreras *et al.* (1990), Darrieu (1983b), Dorge (1996), Eisentraut (1935), Galetti (1993), Galetti & Rodrigues (1992), Guix (1995), Hayes (1995), Inskipp *et al.* (1988), Lantermann & Wozniak (1986), Low (1972), Naumburg (1930), Nores & Yzurieta (1994), de la Peña (1988), Pinto (1946, 1964), Pizo *et al.* (1995), Ridgely (1981), do Rosário (1996), Short (1975), Sick (1985, 1993), Smith (1960), Stotz *et al.* (1996), Tell (1983), Wetmore (1926), Whitney (1996), Willis & Oniki (1981).

298. Speckle-faced Parrot

Pionus tumultuosus

French: Pionne pailletée **German:** Purpurstirnpapagei **Spanish:** Loro Tumultuoso

Other common names: Plum-crowned Parrot (*tumultuosus*); White-capped/White-headed Parrot (*seniloides*)

Taxonomy. *Psittacus tumultuosus* Tschudi, 1844, Peru. Race *seniloides* often regarded as a separate species, but differences between them slight and superficial, appearing more appropriate for subspecific separation. Two subspecies recognized.

Subspecies and Distribution.

P. t. seniloides (Massena & Souancé, 1854) - W Venezuela through CE Colombia and N Ecuador to NW Peru.

P. t. tumultuosus (Tschudi, 1844) - C & S Peru and mountains of Bolivia E to Santa Cruz.

Descriptive notes. 29-30 cm; 229 g. Forehead and crown plum; bare orbital ring greyish; face flecked plum-pink on dull purple, which extends onto breast; back, wings and belly green; undertail-coverts and tail basally dull red, rest of tail green, blue on outer feathers. Immature has crown and breast green, tail-coverts yellowish green. Race *seniloides* replaces plum with pink-flecked white on forehead shading into faint whitish scaling on purplish nape and sides of face; belly dull brown.

Habitat. Humid subtropical forests and tall cloud forest with bamboo thickets, elfin forest and wooded ravines in páramo at 2000-3000

m, occasionally ranging into adjacent agricultural land.

Food and Feeding. Virtually undocumented. Fruits of *Turpinia paniculata* and a member of Clusiaceae. Visits to maize fields occur and damage may once (when birds more numerous) have been considerable.

Breeding. Nov-Dec (*tumultuosus*). Details apparently unrecorded in either race in wild. In captivity: 4 eggs; incubation period c. 26 days.

Movements. Nomadic, especially in N of range, with seasonal variations in numbers.

Status and Conservation. Not globally threatened. CITES II. Generally uncommon and local. Overall status difficult to judge owing to nomadism, but nominate *tumultuosus* regarded as more numerous than *seniloides*, perhaps because the drier forests of former's habitat tend to produce more fruit than the wet ones used by latter. Moreover, deforestation in N of range more extensive and decline probable in most of range; habitat destruction a major threat to Venezuelan populations, but common in Loja, S Ecuador. Very little trade internationally.

Bibliography. Bond & Meyer de Schauensee (1943), Desenne & Strahl (1991, 1994), Fjeldsá & Krabbe (1990), Hilty & Brown (1986), Low (1972, 1995e), Meyer de Schauensee & Phelps (1978), O'Neill (1981), O'Neill & Parker (1977), Peters & Griswold (1943), Remsen & Traylor (1989), Ridgely (1981), Ridgely & Gaulin (1980), Smith, G.M. (1993), Stoodley (1978a), Stotz *et al.* (1996), Wheatley (1994), Whitney (1996).

299. White-crowned Parrot

Pionus senilis

French: Pionne à couronne blanche **German:** Glatzenkopfpapagei **Spanish:** Loro Senil

Other common names: White-capped Parrot(!)

Taxonomy. *Psittacus senilis* Spix, 1824, Vera Cruz, Mexico. Populations from Belize and adjacent parts of Yucatán S to Panama formerly awarded race *decoloratus*. Monotypic.

Distribution. NE Mexico S, mainly on Caribbean slope, to W Panama.

Descriptive notes. 24 cm; 193-229 g. Lores, forehead and mid-crown white; bare orbital ring flesh yellow; face and nape dark green finely edged blue; upper breast patch white; remainder of undersides green thickly edged blue, less so on abdomen; undertail-coverts and tail basally red, tail otherwise green with blue outer feathers; back green; wing-coverts green edged buff; primaries dark blue. Female somewhat duller. Immature has reduced or no white.

Habitat. Humid tropical evergreen forest, pine-oak woodland and cloud forest, pine savanna, riverine forest, semi-open areas and clearings, plantations and agricultural areas

with scattered groves, generally ranging up to 1600 m, even 2300 m in Guatemala.

Food and Feeding. Fruits, seeds and nuts such as ripening seeds of *Inga*, *Erythrina*, palms and *Dendropanax*.

Breeding. Mar in Mexico; Feb-May in Belize, and probably also Guatemala; Jan-Apr in Costa Rica. Nest in hole in tree or, probably by preference, in palm stub. Eggs 3-6; in captivity, incubation, by female only, lasted 26-28 days, and nestling period 54-68 days.

Movements. Unclear patterns reported in Mexico, where in one winter (1950) all records were at 1250-1560 m and in the next all were at 160-300 m; and birds disappeared from a site in Oaxaca for a five-week period in Feb-Mar 1961. In Costa Rica a sporadic visitor, especially after breeding, to Valle Central.

Status and Conservation. Not globally threatened. CITES II. Generally common, perhaps reaching maximum abundance in Costa Rica, where even in urban outskirts. Possibly now extinct in W Nicaragua owing to extensive habitat loss, and naturally rare at edge of range in Panama. There are no reports of persecution for the damage they are reported to do to maize, sorghum and cultivated fruit, and trade is surprisingly low, with 6413 birds (85% of total volume) exported from Honduras, 1985-1990, since when Honduras has banned commerce in the species.

Bibliography. Anon. (1993), Binford (1989), Clinton-Eitner (1982a), Edwards & Lea (1955), González-García (1993), Harrison & Holyoak (1970), Howell, S.N.G. & Webb (1995a), Howell, T.R. (1964), Huber (1933), Land (1970), Loetscher (1941), Low (1972), Lowery & Dalquest (1951), Monroe (1968), Paynter (1955), Ridgely (1981), Ridgely & Gwynne (1989), Russell (1964), Slud (1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Tashian (1952), Wetmore (1968), Whitney (1996), Zimmerman (1982, 1983).

300. Bronze-winged Parrot

Pionus chalcopterus

French: Pione noire

German: Glanzflügelpapagei

Spanish: Loro Alibronceado

Taxonomy. *Psittacus chalcopterus* Fraser, 1841, Bogotá, Colombia.

Proposed race *cyaneus*, from S Colombia to Peru, very weakly marked and doubtfully valid. Monotypic.

Distribution. W Venezuela and NE Colombia S through Ecuador to NW Peru.

Descriptive notes. 28-29 cm; 210 g. Head and neck bronze-brown to very dark navy blue with bare orbital ring flesh, bill yellow, and chin flecked white with pink scaly bib below on deep blue undersides; back, mantle, scapulars and wing-coverts bronze; lower back, rump, flight-feathers and tail deep blue; undertail-coverts and tail basally dull red. Immature has head and upperparts greenish, underparts browner.

Habitat. Humid foothill and highland cloud forest, borders, partially cleared areas with scattered trees, penetrating drier deciduous woodland in S of range; mostly 1400-2400 m, though as low as 120 m in N of range, and up to 2800 m.

Food and Feeding. Poorly documented. Seen feeding on fruits of *Guazuma ulmifolia* and flushed from fruiting *Ficus*; small seeds also recorded.

Breeding. Mar-May in Colombia. Nest in hole in dead tree. In captivity: 2 eggs; incubation 26 days; and nestling period around 2 months.

Movements. Nomadic at least in Colombia, where populations on W slope of E Andes and E slope of W Andes disappear for major portions of the year. In Peru there may be immigration in the wet season, Dec-Apr.

Status and Conservation. Not globally threatened. CITES II. Although at least recently locally common in SW Colombia and W Ecuador, on "Blue List" for former and threatened in latter by rapid forest loss, and less numerous in rest of range where substantial declines must already have occurred in response to extensive habitat clearance. Population in Tumbes National Forest, NW Peru, may only be a few hundred and probably less than 500 occur in the country at any one time. Little traded internationally, but under some pressure in Venezuela.

Bibliography. Attrill (1991), Ball (1993), Butler (1979), Desenne & Strahl (1991, 1994), Fjeldså & Krabbe (1990), Harrison & Holyoak (1970), Hilty (1985), Hilty & Brown (1986), Inskipp *et al.* (1988), Low (1972, 1976), Meyer de Schauensee & Phelps (1978), O'Neill (1981), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1995), Pulido (1991), Ridgely (1981), Ridgely & Gaulin (1980), Stoodley (1974), Stotz *et al.* (1996), Whitney (1996), Yezp (1953).

301. Dusky Parrot

Pionus fuscus

French: Pione violette

German: Veilchenpapagei

Spanish: Loro Morado

Taxonomy. *Psittacus fuscus* P. L. S. Müller, 1776, Cayenne.

Monotypic.

Distribution. NE Venezuela, the Guianas and N Brazil to lower Amazon at Manaus and E to Maranhão; also the Perijá range on Colombia-Venezuela border.

Descriptive notes. 25-26 cm; 179-229 g. Head slaty blue, with small indistinct red patch below nares and pale bluish grey bare orbital ring; face fringed with indistinct ring of white; upperparts dark brown with paler edging to feathers; underparts variably dark, typically tending to be reddish chocolate, with diffuse barring; undertail-coverts and base of tail dull red; rest of tail and wings dark blue. Immature similar to adult but with wing-coverts edged green.

Habitat. Inhabits humid tropical evergreen *terra firme* forest and, to a lesser extent, seasonally flooded *várzea* and permanently

flooded *igapó* forest, mostly below 600 m; seasonally penetrates sand-ridge forest and savanna woodland in N of range in Surinam, while in French Guiana it is commoner in coastal gallery woodland than in the interior forests. In Perijá range, humid foothill and lower highland forest and edge at 1200-1800 m.

Food and Feeding. Very poorly documented. Seeds of *Eschweilera subgrandulosa* and *Micropholis melinoneana* recorded.

Breeding. Apr in Colombia; Mar-Apr in Guyana; Feb in French Guiana; Nov in Pará, N Brazil. Nest in hole in dead tree. Eggs 4.

Movements. In Surinam birds visit coastal area Jun-Aug.

Status and Conservation. Not globally threatened. CITES II. Fairly common throughout range, and only likely to have declined in area in S and E of range in response to widespread habitat clearance in region; certainly reported as abundant in Pará in 1910's, clearly less so now. Very little evidence of local or international trade involving Venezuela and Guyana.

302. Cuban Amazon

Amazona leucocephala

French: Amazone de Cuba **German:** Kubaamazonen **Spanish:** Amazona Cubana
Other common names: Cuban Parrot, White-headed Amazon/Parrot

Taxonomy. *Psittacus leucocephalus* Linnaeus, 1758, eastern Cuba. Forms superspecies with *A. collaria* and *A. ventralis*, and all may be conspecific. Birds of I of Pines formerly awarded race *palmarum*. Four subspecies recognized.

Subspecies and Distribution.

A. l. bahamensis (Bryant, 1867) - Bahamas, on Great Inagua and Abaco.

A. l. leucocephala (Linnaeus, 1758) - Cuba and I of Pines.

A. l. caymanensis (Cory, 1886) - Grand Cayman I.

A. l. hestern Bangs, 1916 - Cayman Brac and formerly Little Cayman.

Descriptive notes. 32 cm; 222-232 g. Forehead, crown and area round eyes white, including bare white periorbital ring; lores, cheeks and throat pinkish red; ear-coverts blackish; purplish patch on belly; remainder of body green with dark edging making scaled effect (also on belly patch); flight-feathers soft blue; tail green tipped yellowish, outer feathers with red basally and margined blue. Immature less strongly scaled, less purple on belly. Race *caymanensis* has white on mid-crown, pinkish red on moustachial area and belly patch all reduced; *hestern* smaller, with larger belly patch; *bahamensis* often with no belly patch,

white of crown more extensive below and behind eye.

Habitat. Limestone forest, dry mixed broadleaf woodland, savanna with stands of pine *Pinus caribaea* and palms, mangroves, plantations and gardens.

Food and Feeding. Fruits and/or seeds of wide variety of plants, notably unripe *Pinus caribaea*, plus *Bursera*, *Ficus*, *Petitia*, *Smilax*, *Sabal*, *Duranta*, *Exothea*, *Ernodia*, *Ilex*, *Zamia*, *Tabebuia*, *Acacia*, *Metopium*, *Tetrazygia*, *Myrcanthes*, *Coccoloba*, *Conocarpus*, *Swietenia*, *Manilkara*, *Cupania*, *Lysiloma*, and several palms; also stems of *Cassytha* vines, *Avicennia* and *Bucida* blossoms, and buds, plus cultivated fruit such as mango and papaya.

Breeding. Mar-Jun. Nest in hole in tree, e.g. *Avicennia* mangrove and various palms; on Abaco in limestone holes in ground. Eggs 2-6; incubation 26-28 days; nestling period 56-60 days.

Movements. No information, but some wandering outside the breeding season likely on Cuba.

Status and Conservation. Not globally threatened. CITES I. Currently considered near-threatened. Still common in remoter forested areas of Cuba and present in some national parks, but population declining from habitat loss and estimated at 5000 in 1988. Formerly present on several islands in Bahamas and on Little Cayman; causes of extinction there unknown. Population rise of *caymanensis* on Grand Cayman from 1500 in 1992 to 1900 in 1995, possibly owing to protection from hunting, but habitat still under pressure. Population on Cayman Brac 299-430 in 1991. Population on I of Pines 1384 in Dec 1995. Great Inagua population receives some protection from 743 km² Bahamas National Trust Park; Abaco population 830-1082 in 1989, threatened by cat predation, trade, poaching and habitat loss, though these recently the target of controls.

Bibliography. Anon. (1983, 1995e), Atrill (1981), Barbour (1943), Beissinger & Snyder (1992), Berovides (1986), Bond (1985), Boosey (1957), Bradley (1986), Brudenell-Bruce (1975), Brykezyński (1985), Buden (1987), Carraway & Carraway (1979), Decoteau (1983), Dorge (1997), Fitzgerald & Larson (1989), Gálvez-Aguilera (1997), Gálvez-Aguilera & Berovides-Álvarez (1997), Garrido & Schwartz (1968), Gnam (1987, 1988a, 1988b, 1990a, 1990b, 1991a, 1991b, 1994), Gnam & Burchsted (1991), Gnam & Rockwell (1991), Gnam *et al.* (1997), González *et al.* (1987), King (1976, 1978/79), Llanes *et al.* (1992), Low (1972, 1987c, 1994b, 1996b), McGrath & Greenwell (1978), Mitchell & Wells (1997), Moore (1985), Nichols (1981a), Noegel (1974, 1975, 1976, 1977, 1979a, 1979c, 1981), Parkes (1963), de las Pozas & González (1984a, 1984b), Rodríguez & Acosta (1986), Silva (1995), Snyder, King & Kepler (1982), Snyder, Wiley & Kepler (1987), Stoodley (1980), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Sulley & Sulley (1992), Them (1995), Weissweiler (1987), Whitney (1996), Wiley (1991b), Wiley *et al.* (1992).

303. Yellow-billed Amazon

Amazona collaria

French: Amazone sasabé **German:** Jamaikaamazonen **Spanish:** Amazona Jamaicana Piquiclara
Other common names: Yellow-billed Parrot

Taxonomy. *Psittacus collaris* Linnaeus, 1758, Jamaica.

Forms superspecies with *A. leucocephala* and *A. ventralis*, and all may be conspecific. Monotypic.

Distribution.

Descriptive notes. 28 cm. Similar to *A. leucocephala* but with scaled effect confined to head and nape, and with white of mid-crown replaced with dull blue, ear-coverts greyish blue. Immature like adult.

Habitat. Mid-level wet limestone forest to 1200 m, but ranging down to sea-level and into semi-wooded areas and cultivations.

Food and Feeding. Fruits, seeds, blossoms and leaf buds, species including *Cecropia*, *Ficus*, *Annona*, *Citrus* and *Rubus*, plus cultivated fruit crops.

Breeding. Mar-May. Nest in hole in tree, frequently breadnut (*Brosimum*) but often in old woodpecker cavity; rarely below 18 m. Eggs 3-4; incubation 24-25 days; nestling period c. 10 weeks.

Movements. Birds wander more widely on a daily basis than sympatric *A. agilis*.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. Slowly decreasing as habitat steadily cleared, but still in reasonable numbers.

Bibliography. Anon. (1983), Arman & Arman (1983a, 1983b), Bond (1985), Cook *et al.* (1984), Cruz (1974), Cruz & Gruber (1981), Danforth (1928), Decoteau (1983), Downer (1976), Downer & Sutton (1990), Fairbairn (1981), Gruber (1980), Hurst (1982), Lack (1976), Low (1972, 1994b), Moffat (1972), Snyder *et al.* (1987), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Varty (1991), Wauer (1996), Whitney (1996), Wiley (1991b).

304. Hispaniolan Amazon

Amazona ventralis

French: Amazone d'Hispaniola **German:** Häitiamazone **Spanish:** Amazona de la Española
Other common names: Hispaniolan Parrot

Taxonomy. *Psittacus ventralis* P. L. S. Müller, 1776, Martinique; error = Hispaniola.

Forms superspecies with *A. leucocephala* and *A. collaria*, and all may be conspecific. Monotypic. **Distribution.** Hispaniola, occurring in both Haiti and Dominican Republic; also on satellite islands. Introduced to Puerto Rico and US Virgin Is.

Descriptive notes. 28 cm. Similar to *A. leucocephala* but with pinkish red of lower face and throat reduced to a few flecks on throat, otherwise replaced by green; scaled effect also reduced, and white restricted to forecrown and lores, bordered by blue suffusion; belly patch maroon; ear-coverts blackish or dark blue. Immature lacks blue suffusion on crown and cheeks, belly patch paler.

Habitat. Arid lowland palm savanna and more humid montane evergreen forest, to 1500 m.

Food and Feeding. Fruits and seeds of palms, cacti, *Caesalpinia* and guava (*Psidium*), with cultivated plants such as bananas

and maize commonly also taken.

Breeding. Feb-May. Nest in hole in tree, commonly a woodpecker hole in palm trunk; also in cactus. Eggs 2-4; in captivity, incubation c. 25 days, and nestling period 8 weeks.

Movements. Daily feeding movements may be pronounced. No other information.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. A BirdLife "restricted-range" species. Subject to highly variable reports on status, having undergone a decline throughout Hispaniola owing to habitat clearance, poaching for food, trapping for trade and shooting as a crop pest; however, still locally common although mostly uncommon to rare.

Bibliography. Almonte & Hierro (1996), Anon. (1983), Bacelar (1980), Bond (1985), Decoteau (1983), Dod (1981, 1987, 1992), Gates (1971), Jeggo (1981), Lever (1987), Low (1972, 1994b), Raffaele (1989), Robiller & Trogisch (1984a), Schwartz (1970a), Silva (1982), Snyder *et al.* (1987), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Wauer (1996), Wetmore & Swales (1931), Whitney (1996), Wiley (1991b), Wiley *et al.* (1976).

305. White-fronted Amazon

Amazona albifrons

French: Amazone à front blanc **German:** Weißstirnamazone **Spanish:** Amazona Frentialba
Other common names: White-fronted Parrot

Taxonomy. *Psittacus albifrons* Sparrman, 1788, south-western Mexico.

Three subspecies recognized.

Subspecies and Distribution.

A. a. saltuensis Nelson, 1899 - NW Mexico.

A. a. albifrons (Sparrman, 1788) - S Mexico and SW Guatemala.

A. a. nana W. DeW. Miller, 1905 - E Mexico, Belize and N Guatemala SE to W Costa Rica.

Descriptive notes. 25-29 cm; 176-242 g. Forecrown white; large facial patch around eye red; mid- to hindcrown dull blue with feather edges dark creating scaled effect; lower cheeks emerald green, shading to yellower green underparts, with dark scaling on breast fading out on belly; upperparts green with dark scaling; large red patch on leading edge of wing, with dark blue speculum and blue tips to flight-feathers; tail green with yellow tips and red bases to outer rectrices. Female lacks red in wing. Immature with reduced red on face. Race *saltuensis* washed glaucous; *nana* smaller.

Habitat. Chiefly drier, deciduous forest, advanced second growth, scrubby woodland, thornbush, coastal palm-fig thickets, semi-open areas with scattered trees and giant cacti, woodlots in savanna, mangroves and agricultural land, in lowlands and foothills to 1850 m; also in lowland evergreen forest and pinelands. Where sympatric with *A. xantholara*, inhabits wetter, more closed vegetation.

Food and Feeding. Seeds, including *Inga* and other legumes, *Croton*, *Terminalia*, plus blossoms, berries, fruits, notably of *Ficus* and cacti such as *Pachycereus* and *Lemaireocereus*; also corn, mangoes and other crops.

On following pages: 306. Yellow-lored Amazon (*Amazona xantholara*); 307. Black-billed Amazon (*Amazona agilis*); 308. Puerto Rican Amazon (*Amazona vittata*); 309. Tucuman Amazon (*Amazona tucumana*); 310. Red-spectacled Amazon (*Amazona pretrei*); 311. Red-crowned Amazon (*Amazona viridigenalis*); 312. Lilac-crowned Amazon (*Amazona finschi*); 313. Red-lored Amazon (*Amazona autumnalis*); 314. Blue-cheeked Amazon (*Amazona dufresniana*); 315. Red-browed Amazon (*Amazona rhodocorytha*); 316. Red-tailed Amazon (*Amazona brasiliensis*); 317. Festive Amazon (*Amazona festiva*).

Breeding. Jan-May in Mexico and Guatemala. Nest in natural cavities in trees and woodpecker holes. Eggs 3-5; incubation in captivity, by female only, 24 days.

Movements. Local seasonal movements occur, presumably as rain makes fringe habitats temporarily attractive: spring and summer visitor to arid lowlands, El Salvador; summer (Jul-Aug) visitor lower mountains, E Guatemala.

Status and Conservation. Not globally threatened. CITES II. Frequent to abundant, and with *Aratinga canicularis* the most numerous parrot on Pacific slope of Middle America, with no obvious decline, and indeed may benefit from habitat fragmentation. Possibly a crop pest in parts of range. Fairly heavily traded at least in Mexico.

Bibliography. Berlanga & Castillo (1989), Berman (1984), Binford (1989), Chapman *et al.* (1989), Clarke (1982), Davis (1944), Decoteau (1983), Dickey & van Rossem (1938), Howell & Webb (1995a), Inskipp *et al.* (1988), Land (1970), Lantermann (1984), Lever (1987), Levinson (1979, 1981), Lewis (1971, 1972), Low (1972), Monroe (1968), Muschellik & Stegweit (1985), Orians (1969), Paynter (1955), Ridgely (1981), van Rossem (1945), de Ruiter (1993a), Russell (1964), Short (1974), Skeate (1984, 1985), Slud (1964), Stiles & Skutch (1989), Stoodley & Stoodley (1990), Stoitz *et al.* (1996), Thurber *et al.* (1987), Wetmore (1944), Whitney (1996).

306. Yellow-lored Amazon

Amazona xantholora

French: Amazone du Yucatan **German:** Goldzügelamazone **Spanish:** Amazona Yucateca
Other common names: Yellow-lored Parrot, Yucatan Amazon/Parrot

Taxonomy. *Chrysotis xantholora* G. R. Gray, 1859, Honduras. Monotypic.

Distribution. Yucatán Peninsula in S Mexico (including Cozumel I) and N Belize; possibly also Roatán I, Honduras.

Descriptive notes. 26-28 cm; 200-232 g. Very like *A. albifrons* but with lores yellow, white of forehead extending to mid-crown, large black patch on ear-coverts, red in wing restricted to primary coverts. Female replaces white on head with dull blue, and has reduced red on face, ear-coverts dark grey, primary coverts green. Immature has red in face still further reduced.

Habitat. Open, dry vegetation, deciduous scrub forest and pine woodlands, and margins of humid forest. Occurs up to 100 m.

Food and Feeding. No certain information; probably similar to *A. albifrons*.

Breeding. Mar-Apr. Nest in hollow in tree, e.g. top of dead stump. Eggs 4; incubation 22-23 days. **Movements.** Large flocks fly across from mainland to Cozumel I every day in order to feed, returning to mainland in evening to roost.

Status and Conservation. Not globally threatened. CITES II. Common to abundant in most of restricted range, becoming rarer at periphery. Little trade recorded. Status of habitat on Mexican part of Yucatán, and on Cozumel, needs clarification.

Bibliography. Berlanga & Castillo (1989), Clinton-Eitner (1982b), Decoteau (1983), Griscom (1926), Howell & Webb (1992, 1995a), Klaas (1968), Low (1972), Monroe (1968), Paynter (1955), Ridgely (1981), Russell (1964), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Sweeney (1997c), Whitney (1996).

307. Black-billed Amazon

Amazona agilis

French: Amazone verte **Spanish:** Amazona Jamaicana Piquioscura
German: Rotspiegelamazone
Other common names: Black-billed Parrot

Taxonomy. *Psittacus agilis* Linnaeus, 1758, Jamaica. Monotypic.

Distribution. Jamaica.

Descriptive notes. 25 cm; 178 g. Green, paler on underparts and yellowish green on undertail-coverts; often red flecks on forehead; feather edges on nape dark, giving slight scaled effect; primary coverts red, primaries soft blue, darker at tips, secondaries green and distally dark blue; tail green, outer feathers with red basally and margined blue. Female has some primary coverts green. Immature has all primary coverts green.

Habitat. Wet mid-level limestone forest generally at 500-1600 m.

Food and Feeding. Fruit, seeds, nuts, berries, blossoms and leaf buds, species including *Cecropia*, *Ficus*, *Annona*, *Nectandra*, *Bryophyllum*, *Pithecellobium*, *Melia* and *Blighia*; also cultivated plants such as papaya, mango, cucumber and maize.

Breeding. Mar-May. Nest at least 18 m up in hollow limbs or holes in trees, sometimes old woodpecker holes and bases of bromeliads. Eggs 2-4, usually only 2 young being reared; incubation by female, in captivity lasting 28 days; nestling period (wild) around 8 weeks.

Movements. Temporary local shifts in populations have been found to occur in response to food availability.

Status and Conservation. **VULNERABLE.** CITES II. A BirdLife "restricted-range" species. Formerly considered as common as sympatric *A. collaria*, but now less so and has become very rare in E. Forest clearance and fragmentation, hurricane damage to habitat, poaching for food and trapping for local trade are causing a decline in a population thought to number well under 10,000 mature individuals.

Bibliography. Anon. (1983), Bond (1985), Collar (1996), Collar *et al.* (1994), Cook *et al.* (1984), Cruz (1972, 1979, 1980), Cruz & Gruber (1981), Decoteau (1983), Downer & Sutton (1972, 1990), Fairbairn (1981), Gruber (1980), Kidd (1964, 1965), Knox & Knox (1974), Lack (1976), Low (1972, 1994b), Noegel (1979b, 1980), Salmon (1972), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Tenison (1963), Varty (1991), Wauer (1996), Whitney (1996), Wiley (1991b).

308. Puerto Rican Amazon

Amazona vittata

French: Amazone de Porto Rico

Spanish: Amazona Portorriqueña

German: Puerto-Rico-Amazone

Other common names: Puerto Rican Parrot

Taxonomy. *Psittacus vittatus* Boddaert, 1783, Santo Domingo = Puerto Rico.

Race *gracilipes* of Culebra I, off Puerto Rico, now extinct. One extant subspecies recognized.

Subspecies and Distribution.

A. v. vittata (Boddaert, 1783) - Puerto Rico.

Descriptive notes. 29 cm; 250-300 g. Green, paler on underparts, with feathers edged blackish to give scaled appearance on head, mantle and breast; frontal band red, sometimes extending to lores; bare orbital ring white; belly sometimes tinged dull red; flight-feathers soft blue; tail green tipped yellowish, outer feathers with red basally and margined blue. Immature similar. Race *gracilipes* smaller.

Habitat. Originally throughout forests on Puerto Rico ranging from moist montane forest down to littoral scrub forest and mangroves; now confined to former, at 200-600 m, consisting (ascending order) of tabonuco

Dacryodes excelsa forest, once important for feeding and breeding but much logged, palo colorado *Cyrtilla racemiflora* zone, important for nesting, sierra palm *Prestoea montana* forest, to whose fruiting breeding is timed to coincide, and dwarf forest, used occasionally for food.

Food and Feeding. Fruits, seeds, leaves, flowers and bark of up to 60 food-plants (44 tree species, 7 shrubs and 7 vines) recorded, with *P. montana* most important and *Dacryodes* second; tends to avoid small fruits, favouring species that show pronounced peaks. Crop pest on corn in past century.

Breeding. Feb-Apr. Nest in natural cavities produced by decay, almost always in *Cyrtilla*, optimally at least 4-5 m from ground and at least 60 cm deep, dry and flat-bottomed; formerly also in potholes in limestone cliffs. Eggs 2-4; incubation, by female only, 26 days; nestling period averages 9 weeks, but variable.

Movements. Mostly sedentary; when formerly widespread, probably visited mangroves and littoral scrub forest mostly seasonally.

Status and Conservation. **CRITICALLY ENDANGERED.** CITES I. A BirdLife "restricted-range" species. Clearance of forest in 19th century was so intensive that less than 1% of Puerto Rico's forests were virgin by 1912, when the species's current only site, Luquillo Forest, occupied only around 22.7 km². Collection of birds as pets and persecution for crop depredation greatly reduced numbers in past; the race *gracilipes* was reportedly wiped out by settlers protecting harvests. Ill-founded translocation attempts in 1950's and deliberate radiation exposure of Luquillo Forest in 1960's may have reduced by then already low numbers. Hurricanes (notably Hugo in 1989) cause fatalities. Although rats appear to cause few problems, introduced honeybees occupy nest-sites, bot-flies (*Philornis pici*) parasitize nestlings, and increasing Pearly-eyed Thrashers (*Margarops fuscatus*) destroy nest contents. Attempts have been made to mitigate all these factors through a long-term programme of intensive management, which includes captive breeding and projected restocking of known former areas. Wild population increased from 21-23 after Hugo in 1989 to 42 in late 1994 and c. 60 in 1996, possibly related to greater fruit production in the recovering forest, new nest-site availability and the forced discovery of new breeding areas when birds were dispersed by the winds.

309. Tucuman Amazon

Amazona tucumana

French: Amazone de Tucuman

German: Tucumanamazone

Spanish: Amazona Tucumana

Other common names: Tucuman Parrot, Alder Amazon/Parrot

Taxonomy. *Chrysotis tucumana* Cabanis, 1885, Tucumán, Argentina.

Sometimes considered conspecific with *A. pretrei*, but the two are better regarded as forming a superspecies. Monotypic.

Distribution. S Bolivia (no records since 1938) and NW Argentina.

Descriptive notes. 31 cm; 250-280 g. Green throughout, with feathers strongly edged black to give scaled effect; forehead and sometimes lores red, bare orbital skin white; lower thighs orange-yellow; undertail-coverts yellowish; primary coverts red; primaries tipped dark blue; tail tipped yellowish. Immature has all-green thighs.

Habitat. Open mountain woodland in Andean yungas forest dominated by pure stands of *Alnus acuminata* or *Podocarpus parlatorei*, 1600-2600 m.

Food and Feeding. Seeds of *Alnus* and possibly of *Podocarpus* are probably the virtual year-round staple. Flowers of *Erythrina* and *Morus*, late Aug, immature fruits of *Cedrela*, Sept-Nov.

Breeding. Nov-Jan. Nest in holes in wide old trunks of *Alnus* and *Podocarpus*. Eggs 4; incubation period, in captivity, 26-27 days.

Movements. Chiefly elevational in character, with birds moving to 500 m and lower in the Chaco-yungas transition zone, mid-Aug to Oct.

Status and Conservation. Not globally threatened. CITES I. A BirdLife "restricted-range" species. Generally uncommon but common locally. Present in winter in several protected areas, Argentina, including El Rey National Park. Causes some damage to fruit crops during winter, and is vulnerable to trapping at that season, when entire local populations concentrate at roosts; 18,641 birds were exported, 1985-1989, after which no trade was permitted under CITES. Fully protected (including prohibition of export) in Bolivia since 1984, though no records in wild since 1938.

Bibliography. Babarskas *et al.* (1995), Beissinger & Snyder (1992), Bond & Meyer de Schauensee (1943), Canevari *et al.* (1991), Decoteau (1983), Fjeldså & Krabbe (1990), Hoy (1968), Inskipp *et al.* (1988), Krabbe *et al.* (1996), Low (1972), Mosa *et al.* (1992), Noegel (1982a, 1982b), Nores & Yzurieta (1994), de la Peña (1988), Remsen & Traylor (1989), Ridgely (1981), Stoodley, J. & Stoodley (1990), Stoodley, P. & Stoodley (1983), Stotz *et al.* (1996), VanDerHeyden (1991), Vasicek (1993), Wetmore (1926), Wheatley (1994), Whitney (1996).

310. Red-spectacled Amazon

Amazona pretrei

French: Amazone de Prêtre **German:** Prachtamazone **Spanish:** Amazona Charao
Other common names: Red-spectacled Parrot

Taxonomy. *Psittacus pretrei* Temminck, 1830, Mexico?; error = southern Brazil. Sometimes considered conspecific with *A. tucumana*, but the two are better regarded as forming a superspecies. Monotypic.

Distribution. S Brazil chiefly in Rio Grande do Sul; very rare or vagrant in Paraguay and Argentina.

Descriptive notes. 32 cm. Similar to *A. tucumana*, but red on head extends to mid-crown and around bare orbital skin, often with some flecks on ear-coverts and neck; rest of head lacks dark feather-edging; red in folded wing extends from shoulders to primary coverts; lower thighs mixed with red. Immature has reduced red on head and wings.

Habitat. *Araucaria angustifolia* forest in N of range, lowland riverine broadleaf forest in S, with extensive seasonal use of *Podocarpus lambertii* groves. Major breeding area appears to be in savanna region in SE of range, in open woodland dominated by *Podocarpus*, *Lythraea*,

Scutia, *Celtis*, *Allophylus*, *Eugenia*, *Schinus* and *Sebastiania* species.

Food and Feeding. Variety of fruit in spring and summer (Oct-Feb), notably *Cupania*, *Eugenia*, *Phytolacca*, *Allophylus*, *Nectandra*, *Ocotea*, *Campomanesia*, *Cytharexylum*, *Myrcianthes*, *Blepharocalyx*, *Ficus* and *Symplocos*, with some populations heavily exploiting *Podocarpus* in Jan-Feb; in late autumn and winter (May-Aug) birds concentrate on seeds of *Araucaria*.

Breeding. Sept-Dec. Nest in hole in tree, generally fairly low (mean 6-5 m from ground); *Nectandra*, *Ocotea*, *Cupania* and *Sebastiania* are commonest nest-tree species. Eggs 2-4; incubation in captivity 26-27 days; fledging from as early as 50 days.

Movements. Partial migrant: birds breeding in SE and some in NC parts of range move to NE of range and into Santa Catarina in winter, straggling to E Paraguay. Fruit production in *Araucaria* is reported to be cyclically variable, and in periods of poor seed production birds probably wander much more widely during May-Aug.

Status and Conservation. ENDANGERED. CITES I. A BirdLife "restricted-range" species. Formerly abundant, but major decline over 20th century in response to destruction and fragmentation of habitat compounded by trade at national level. Collectors usually remove all nestlings, cutting and often destroying nests in process; this now probably major threat to species. Despite the presence of many protected areas within the species's range, none is adequate either in staffing levels or in size. Wild population in early 1990's estimated at 7500-8500 birds.

Bibliography. Beissinger & Snyder (1992), Belton (1984), Brooks, Barnes *et al.* (1993), Brooks, Clay *et al.* (1995), Canevari *et al.* (1991), Chebez (1985, 1994), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Decoteau (1983), Diefenbach & Goldammer (1986b), Hayes (1995), King (1978/79), Low (1972, 1991c, 1991d, 1991e, 1991h), Lowen *et al.* (1996), Nores & Yzurieta (1994), de la Peña (1988), Ridgely (1981), do Rosário (1996), Scherer-Neto (1991), Sick (1985, 1993), Sick & Teixeira (1979), Silva, F. (1981), Silva, T. (1991c), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Varty *et al.* (1994a, 1994b), Wege & Long (1995), Whitney (1996).

311. Red-crowned Amazon

Amazona viridigenalis

French: Amazone à joues vertes **German:** Grünwangenamazone **Spanish:** Amazona Tamapulepa
Other common names: Red-crowned Parrot, Green-cheeked Amazon/Parrot

Taxonomy. *Chrysotis viridigenalis* Cassin, 1853, South America; error = north-eastern Mexico. Monotypic.

Distribution. NE Mexico; records from S Texas, USA, possibly refer to wandering wild birds displaced by food shortages in Tamaulipas rather than to escaped cage-birds. Introduced or feral populations in various cities in USA, with small ones in Puerto Rico and Oahu (Hawaiian Is).

Descriptive notes. 33 cm; 294 g. Lores and forehead to mid-crown red, bare orbital ring white, cheeks and ear-coverts bright green, with bluish grey extending from above eye down sides of neck; hindcrown and nape green edged blackish, giving scaled effect; upper- and underparts green, with red speculum, dark blue primaries and broad yellowish tips on outer rectrices. Female and immature have reduced red on head.

Habitat. Tropical evergreen gallery forest in arid lowlands, deciduous woodland on slopes and in canyons, partially cleared areas with groves, and dry open pine-oak stands on ridges up to 1200 m.

Food and Feeding. Nuts, berries, buds, flowers and fruit are taken according to season, with pine seeds important for some populations; acorns, *Pithecellobium* beans, and berries of *Ehretia anagua* and the exotic *Melia azedarach* are specifically recorded. Feral birds adapt to urban parkland food sources such as *Juglans*, *Liquidambar*, *Eucalyptus* and *Chorisa*.

Status and Conservation. ENDANGERED. CITES II. A BirdLife "restricted-range" species. Massively reduced in numbers by high trapping pressure and extensive destruction of habitat. From late 1960's through to early 1980's, when Mexico imposed a ban on exports, the species was traded annually in thousands and in some years, when allowing for smuggling, possibly tens of thousands. Current population judged to be 3000-6500 birds, with no sign of adequate protection from either source of threat. The only substantial protected area in which it occurs is El Cielo Biosphere Reserve, where its status is unknown.

Bibliography. Anon. (1997d), Beissinger & Snyder (1992), Clinton-Eitnienar (1986, 1988, 1989, 1996), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Decoteau (1983), Enkerlin-Hoeflich (1995), Enkerlin-Hoeflich & Hogan (1997), Enkerlin-Hoeflich *et al.* (1993), Froke (1981), Gehlbach (1987), Gehlbach *et al.* (1976), Gildardo (1976), Howell & Webb (1995a), Inskipp & Corrigan (1992), Inskipp *et al.* (1988), Iñigo-Elias & Ramos (1991), Lantermann (1982), Lever (1987), Low (1972), Lowery & Dalquest (1951), Martin *et al.* (1954), Neck (1986), Owre (1973), Pérez & Eguarte (1989), Raffaele (1989), Ridgely (1981), Snyder *et al.* (1987), Spilsbury (1981), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Wege & Long (1995), Whitney (1996), Wozniak & Lantermann (1984), Zimmerman (1957).

312. Lilac-crowned Amazon

Amazona finschi

French: Amazone à couronne lilas **German:** Blaukappenamazone **Spanish:** Amazona Guayabera
Other common names: Lilac-crowned Parrot

Taxonomy. *Chrysotis finschi* P. L. Slater, 1864, Mexico. Forms superspecies with *A. autumnalis*. Proposed northern race *woodi* very poorly differentiated. Monotypic.

Distribution. NW to SW Mexico. Feral population in Los Angeles, USA.

Descriptive notes. 31-34 cm; 282-312 g. Generally green, paler on underparts, where narrow dark feather edging gives light scaled effect, and yellowish on face; lores and forecrown dull red; mid-crown to hindcrown and sides of neck lilac, mixing green and edged dark on nape; carpal area yellowish; speculum red, primaries mostly dark blue, secondaries blue-tipped; tail with yellow tips to outer feathers. Immature similar.

Habitat. Semi-deciduous woodland and edge, dry and humid pine-oak forest in foothills and mountains up to 2200 m, occasionally down to sea-level, where enters mangroves.

Food and Feeding. No specific information on wild food; flocks damage corn and ripening bananas.

Breeding. Mar-May. Nest in hole in tree. Eggs undescribed in wild, possibly only 2; in captivity, incubation 28-29 days, nestling period 60 days.

Movements. Occurrence in flocks outside breeding season suggests some wandering; presence in lowlands believed to be chiefly or only in winter.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. Frequent to common within restricted range, very uncommon in Oaxaca. With commercial export of birds banned in Sept 1982, only tiny numbers have been recorded in trade; local trade is also outlawed. However, it was once and may continue to be a crop pest, and suffer persecution consequently.

Bibliography. Anon. (1993), Binford (1989), Blake & Hanson (1942), Clinton-Eitnienar (1996), Decoteau (1983), Howell & Webb (1995a), Inskipp *et al.* (1988), Lever (1987), Lint (1952), Low (1972), Mann & Mann (1978), Ridgely (1981), van Rossem (1945), Schaldach (1963), Snyder *et al.* (1987), Stager (1954), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Whitney (1996).

313. Red-lored Amazon

Amazona autumnalis

French: Amazone diadème **German:** Rotstirnamazone **Spanish:** Amazona Frentirroja
Other common names: Red-lored Parrot

Taxonomy. *Psittacus autumnalis* Linnaeus, 1758, West Indies; error = southern Mexico. Forms superspecies with *A. finschi*. Races *salvini* (incorporating *lilacina*) and *diadema* may both be incipient species. Four subspecies recognized.

Subspecies and Distribution.

A. a. autumnalis (Linnaeus, 1758) - Caribbean seaboard and slope from E Mexico to N Nicaragua.

A. a. salvini (Salvadori, 1891) - N Nicaragua S to SW Colombia and NW Venezuela.

A. a. lilacina Lesson, 1844 - W Ecuador.

A. a. diadema (Spix, 1824) - lower R Negro and adjacent N bank of Amazon, NW Brazil.

Descriptive notes. 32-35 cm; 314-485 g. Similar to *A. finschi* but replaces deep red of lores and forehead with brighter red, lilac of crown with light mauve-blue, and yellowish green cheeks with yellow. Immature has less red on head, and yellow cheeks flecked green. Race *salvini* has duller yellowish green cheeks, duller but more extensive blue on hindcrown and nape, and basal red in outer tail; *lilacina* similar with red superciliary and yellower cheeks; *diadema* like *salvini* with dark red lores, lilac from mid-crown, greener on nape.

Habitat. Edges of humid evergreen to semi-deciduous lowland and foothill forest, gallery woodland and semi-open areas with scattered trees, plantations and groves, less common in continuous blocks of forest; in Ecuador also enters dry scrubby forest. Ranges up to 1100 m, but usually much lower.

Food and Feeding. Fruits of palms, *Cordia lutea*, *Spondias purpurea*, and *Minquartia*, arillate seeds of *Stemmadenia donnell-smithii*, *Virola*, *Casearia* and *Protium*, figs, ripening legume seeds, leaf buds and some cultivated fruit including mangoes, citrus and even coffee beans.

Breeding. Feb-May in Central America; Dec-Feb in Colombia; Jan-Mar in Ecuador. Nest in hole in tall, usually dead tree, often a palm stub but also e.g. *Ceiba* or *Tabebuia*. Eggs 3-4; incubation in captivity 25-26 days.

Movements. Nothing recorded; year-round resident in NE Mexico.

Status and Conservation. Not globally threatened. CITES II. Relatively common everywhere except NE Mexico, W Venezuela and Ecuador, and in many parts of Central America the commonest amazon and sometimes one of the most numerous psittacids. Decline in NE Mexico and W Venezuela owing to high rates of trapping and extensive habitat loss. Race *lilacina* threatened owing to widespread habitat loss (although persists in disturbed fragments) and trapping presumably for domestic consumption (since both *lilacina* and *diadema* are rare in aviculture); around 400-600 birds are thought to survive. Honduras was chief source of internationally traded birds, 1981-1985, with 13,712 exported in that period.

Bibliography. Binford (1989), Birt (1996), Clinton-Eitner (1984b), Coates-Estrada *et al.* (1993), Decoteau (1983), Desenne & Strahl (1991, 1994), Enkerlin-Hoeflich (1995), González-García (1993), Haase (1986), Harrison & Holyoak (1970), Hilty & Brown (1986), Howell & Webb (1995a), Inskipp *et al.* (1988), Kunz & Abs (1996), Land (1970), Lever (1987), Low (1972, 1987d), Lowery & Dalquest (1951), Meyer de Schauensee & Phelps (1978), Monroe (1968), Pérez & Eguarte (1989), Pilgrim (1997), Ridgely (1981), Ridgely & Gwynne (1989), Russell (1964), Sick (1985, 1993), Slud (1964), Spilbury (1981), Stiles & Skutch (1989), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Strunden *et al.* (1987), Wetmore (1968), Whitney (1996), Willis (1977), Willis & Eisenmann (1979).

314. Blue-cheeked Amazon

Amazona dufresniana

French: Amazone de Dufresne **German:** Goldmaskenamazone **Spanish:** Amazona Cariazul
Other common names: Blue-cheeked Parrot

Taxonomy. *Psittacus dufresnianus* Shaw, 1812, Cayenne.

Possibly forms a superspecies with *A. rhodocorytha* and *A. brasiliensis*; has been treated as conspecific with former, or even both. Monotypic.

Distribution. SE Venezuela, the Guianas and possibly adjacent Brazil.

Descriptive notes. 34 cm; 481-615 g. Forehead and lores orange-yellow; crown yellowish with broad dull green edges to feathers, giving somewhat mottled look; cheeks and ear-coverts royal blue; upperparts dull green, with dark scaling effect on back, underparts slightly paler, yellower on vent and undertail-coverts; carpal edge yellowish green, bright yellow speculum, primaries blackish; tail green with yellowish outer tips. Immature undescribed.

Habitat. Interior tropical zone forests up to 550 m in the Guianas, visiting coastal sand-ridge forests fairly briefly and irregularly (cool season); subtropical forest at 1100-1700 m in

tepui region in W of range, and probably everywhere with a preference for slightly cooler areas.

Food and Feeding. When visiting coastal areas, said to eat seeds of *Hura crepitans* and probably mimosa and other berries. No further information.

Breeding. Mar in Guyana. In captivity: 3 eggs; incubation period 23-26 days. No further information available.

Movements. Poorly understood migration occurs in at least part of the population in the Guianas, with varying numbers of birds visiting coastal sand-ridge forests Jun-Aug depending on year and apparently in response to food availability.

Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. Generally uncommon and at low densities; apparently rarer than in last century, for reasons unknown. Threatened nationally in Venezuela by deforestation. Traded very little, perhaps most frequently for food and as pets in the far E of its range. Recorded from Roraima National Park (Venezuela) and Brownsberg Nature Park (Surinam).

Bibliography. Beissinger & Snyder (1992), Collar (1995), Decoteau (1983), Desenne & Strahl (1991, 1994), Haverschmidt & Mees (1994), Low (1972, 1996a), McLoughlin & Burton (1970), Meyer de Schauensee & Phelps (1978), Olier (1994, 1995), Ridgely (1981), Snyder (1966), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Tostain *et al.* (1992), Wege & Collar (1991), Wheatley (1994), Whitney (1996).

315. Red-browed Amazon

Amazona rhodocorytha

French: Amazone à sourcils rouges **German:** Rotscheitelamazone **Spanish:** Amazona Coronirroja
Other common names: Red-crowned/Red-topped/Red-fronted Amazon/Parrot, Red-browed Parrot

Taxonomy. *Chrysotis rhodocorytha* Salvadori, 1890, Brazil.

Possibly forms a superspecies with *A. dufresniana* and *A. brasiliensis*; has been treated as conspecific with former, or even both. Monotypic.

Distribution. E Brazil in Alagoas and from Bahia S to Rio de Janeiro and São Paulo.

Descriptive notes. 35 cm. Orange red lores and crown shading to brownish purple on hindcrown, with rest of area round bill yellowish pink; cheeks bluish to violet-blue, greener on ear-coverts; nape, mantle and sides of neck green edged dark; remaining body and wings green, paler below, with small red speculum and black primaries, secondaries tipped dark blue; outer tail feathers with red subterminal patch fringed yellowish. Immature with red much reduced on head, wings and tail.

Habitat. Humid lowland forest, though also ranging into interior highlands to 900 m.

Food and Feeding. No species-specific information beyond fruit of "cajuíra" (presumably cashew nuts).

Breeding. Evidence suggests Sept-Nov, as is usual in Atlantic forest birds. In captivity: 4 eggs; incubation 24 days; nestling period 34 days.

Movements. Some displacement to mangroves noted, around Jun, in nineteenth century.

Status and Conservation. **ENDANGERED.** CITES I. Small populations highly fragmented by chronic deforestation within range, and gene exchange between many or all of them may no longer be possible. Meanwhile, birds

are still trapped for local trade. Species is present but not secure in Monte Pascoal National Park (Bahia), Rio Doce and Ibitipoca State Parks (Minas Gerais), Córrego Grande, Córrego do Veadó, Sooretama and Augusto Ruschi Biological Reserves (Espírito Santo), near Desengano State Park (Rio de Janeiro) and Serra da Bocaina National Park (São Paulo).

Bibliography. Beissinger & Snyder (1992), Camargo (1962), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Decoteau (1983), Forrester (1993), Gonzaga *et al.* (1987), Low (1972, 1987c, 1996c), Mann & Mann (1982), Pinto (1935, 1964), Pinto & Camargo (1961), Reillo (1993), Ridgely (1981), Robiller & Trogisch (1984c), Sick (1969, 1972, 1985, 1993), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Sweeney (1997f), Tobias *et al.* (1993), Wege & Long (1995), Whitney (1996).

316. Red-tailed Amazon

Amazona brasiliensis

French: Amazone à joues bleues **German:** Rotschwanzamazone **Spanish:** Amazona Colirroja
Other common names: Red-tailed/Blue-cheeked Parrot

Taxonomy. *Psittacus brasiliensis* Linnaeus, 1758, Brazil.

Possibly forms a superspecies with *A. rhodocorytha* and *A. dufresniana*; has been treated as conspecific with both. Monotypic.

Distribution. SE Brazil in São Paulo and Paraná.

Descriptive notes. 37 cm. Forehead and lores rose-red shading to pink on mid-crown; rest of face pale mauve with soft blue flecking around eye; upper- and underparts green, paler below; carpal area red; wing-coverts broadly edged yellow; flight-feathers tipped dark blue; tail centrally green, broadly tipped yellow, and with broad red subterminal band basally edged dark blue on lateral feathers. Immature undescribed.

Habitat. Breeds and roosts in littoral forests of three types, seasonally and permanently flooded forest and sand-plain forest, dispersing by day to forage in these habitats; also in-

land in lowland humid "Atlantic" rain forest; and in mangroves (where also roosts).

Food and Feeding. Main food plants are *Syagrus romanzoffianum* (fruits, Feb-Apr), *Psidium cattleianum* (fruits, Oct-Dec) and *Calophyllum brasiliense* (fruits, Nov-Dec), but 68 food plants identified to date; seeds, flowers and nectar also taken, and occasionally invertebrates, e.g. beetle larvae within palm exudate, and small spiders and pupae in old seed capsules.

Breeding. Sept-Nov, but some pairs, possibly reneating, with nestlings as late as Apr. Nest in hole 1-15 m up in usually dead tree in flooded forest, mainly *Syagrus* and *Calophyllum*; sometimes in arboreal termitarium or petioles of bromeliad. Density of nests can be high, with 7 nests/ha in sand-plain forest, 18 nests/ha in seasonally flooded forest and 39 nests/ha in permanently flooded forest, this relating to density of dead trees. Eggs 3-4; incubation lasts 27-28 days; fledging probably at around 55 days.

Movements. Some minor wandering in winter (May-Aug) takes birds onto lower slopes of inland hills, but generally not above 200 m.

Status and Conservation. **ENDANGERED.** CITES I. A BirdLife "restricted-range" species. Massive pressure from trappers serving the domestic market who are responsible for almost total annual breeding failure in some populations: thus in 1991-1992 season 356 nestlings were stolen in only 25% of the species' range. "Sport" hunting has also vandalized populations. Construction of holiday homes at the coast, combined with growth in agriculture and ranching, is causing the rapid loss of most remaining lowland forest, and in the early 1990's total available habitat only covered 3057 km²; the selective removal of hardwoods and palms for many purposes is reducing feeding and breeding areas. The total number of birds in São Paulo state, 1993, was 1550, divided up into 16 distinct subpopulations; a figure of 2101 birds for Paraná state, late 1980's, was possibly an overestimate and is likely in any case to be much lower now. The species is present inside several protected areas, but poaching persists in many of them; several new areas have recently been proposed.

Bibliography. Beissinger & Snyder (1992), Bertagnolio (1981, 1983), Camargo (1962), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Curzon (1995, 1996), Decoteau (1983), Diefenbach & Goldhammer (1986a), Forrester (1993), Guix (1995), King (1978/79), Low (1972, 1987c), Lúcker (1996), Martuscelli (1994b, 1995a, 1995b, 1995c), Neto (1988), Ridgely (1981), do Rosário (1996), Scherer-Neto (1988, 1989), Scherer-Neto & Martuscelli (1992), Sick (1969, 1985, 1993), Sick & Teixeira (1979), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Straube (1990), Waugh (1994, 1996b), Wege & Long (1995), Whitney (1996).

317. Festive Amazon

Amazona festiva

French: Amazone tavoua **German:** Blaubartamazone **Spanish:** Amazona Festiva
Other common names: Festive Parrot

Taxonomy. *Psittacus festivus* Linnaeus, 1758, Indies; error, Brazilian Amazon River.

Two subspecies recognized.

Subspecies and Distribution.

A. f. bodini (Finsch, 1873) - E Colombia E through Orinoco basin of Venezuela, sporadically into NW Guyana.

A. f. festiva (Linnaeus, 1758) - SE Colombia, E Ecuador and E Peru E through Amazon basin to W Pará, NC Brazil.

Descriptive notes. 34 cm. General plumage green; lores and frontal band dark red, with pale blue shading above and behind eye, and on chin; slight effect of "scaling" on nape; lower back and rump red; carpal edge yellowish; primaries dark blue; tail tipped yellowish. Immature has less blue on head, and green lower back and rump. Race *bodini* more yellowish below, lores grey-black, forecrown red, face with bluish green tinge.

Habitat. Closely associated with humid low-

land vegetation (to 500 m) along major watercourses: seasonally flooded *várzea* and permanently

flooded *igapó* forest, river islands, riparian growth, gallery forest, seasonally wet savannas. Avoids dryland forest.

Food and Feeding. No information available.

Breeding. Incubation reported as 26-27 days. No further information available.

Movements. Regular or irregular movements may occur, taking the species beyond the normal limits of its range, hence into E Ecuador, Guyana and the Amazon delta, but many apparently extralimital reports need confirmation.

Status and Conservation. Not globally threatened. CITES II. Generally common and stable within restricted but largely intact habitat probably throughout range; locally abundant in upper Amazon. However, in Venezuela suffering from combination of habitat loss and trapping for trade. Rare in trade at least internationally.

Bibliography. Decoteau (1983), Desenne & Strahl (1991, 1994), Hilty & Brown (1986), Low (1972), Meyer de Schauensee & Phelps (1978), O'Neill (1981), Parker *et al.* (1982), Pinto (1964), Pulido (1991), Ridgely (1981), Romero (1978), Sick (1985, 1993), Snyder (1966), Stoodley & Stoodley (1990), Stotz *et al.* (1996), VanDerHeyden (1992), Wheatley (1994), Whitney (1996).

318. Yellow-faced Amazon

Amazona xanthops

French: Amazone à face jaune **German:** Goldbauchamazone **Spanish:** Amazona del Cerrado
Other common names: (Brazilian) Yellow-faced Parrot

Taxonomy. *Psittacus xanthops* Spix, 1824, interior of Minas Gerais. Placement within genus *Amazona* has been questioned. Monotypic.

Distribution. Interior Brazil from Maranhão S to N Paraguay and E Bolivia.

Descriptive notes. 27 cm. Head and neck yellow with green feathering on nape and upper breast; lower breast and belly orange red, with some yellow; belly yellow; thighs and vent grass green; upperparts green with yellow margins to many feathers; tail green, outer feathers yellowish and basally marked red. Immature has reduced yellow on head, rest green; underparts barred yellowish and green. More information needed on age- and sex-related plumage differences.

Habitat. Occurs in wooded grassland (*cerrado*), spiny arid scrub (*caatinga*), gallery forest, and *Mauritia* palm stands.

Food and Feeding. Fruits and seeds, notably legumes and Anacardiaceae; very fond of mangoes, frequenting fruiting trees for weeks.

Breeding. Nest in holes in large *cerrado* trees; incubation 23-24 days.

Movements. Birds disappear from Distrito Federal (Brasília), Apr-Aug. Also shows semi-nomadic movements, ranging over huge areas.

Status and Conservation. **VULNERABLE.** CITES II. The destruction of *cerrado* has been extensive, with 60-70% converted to agriculture in past 20 years; semi-nomadism of the species suggests it depends on unpredictable food resources and cannot be conserved with certainty by the network of reserves within its range.

Bibliography. Antas & Cavalcanti (1988), Cavalcanti (1988), Collar (1996), Collar & Andrew (1988), Collar *et al.* (1994), Decoteau (1983), Low (1972), Olrog (1968), Pinto (1964), Remsen & T aylor (1989), Remsen *et al.* (1986), Ridgely (1981), Robiller *et al.* (1988b), Sick (1985, 1993), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Wheatley (1994), Whitney (1996), Willis (1992).

319. Yellow-shouldered Amazon

Amazona barbadensis

French: Amazone à épaulettes jaunes **Spanish:** Amazona Hombrogualda
German: Gelbflügelamazone
Other common names: Yellow-shouldered Parrot

Taxonomy. *Psittacus barbadensis* J. F. Gmelin, 1788, Barbados; error = Venezuela.

Sometimes placed in genus *Chrysotis*. Proposed race *rothschildi* for Caribbean islands invalid. Monotypic.

Distribution. N Venezuela and islands of Margarita and La Blanquilla; also Bonaire (Netherlands Antilles).

Descriptive notes. 33 cm. Green with narrow dark edges to feathers giving light scaled effect, bluish tinge on underparts; forehead white shading to yellow on mid-crown and around eye, with light blue suffusion on lower cheeks and chin; shoulder and thighs yellow; speculum red, flight-feathers tipped dark blue. Immature lacks bluish tinge below.

Habitat. Xerophytic vegetation such as dry cactus scrubland and thornbush in lowland areas where annual rainfall is less than 1000 mm, but tracts of denser woodland may be important.

Food and Feeding. Fruits, seeds and/or flowers of *Platymiscum*, *Pithecellobium*, *Piptadenia*, *Piscidia*, *Bulnesia*, *Tabeaia*, *Capparis*, *Malpighia*, *Bourreria*, *Casearia*, *Guaiacum*, *Terminalia*, *Spondias*, *Moringa*, *Ziziphus*, *Caesalpinia*, *Crotalaria*, *Acacia*, *Prosopis*, *Leucaena*, *Bursera*, *Crescentia* and various cacti.

Breeding. Mar-May generally, but probably variable with weather conditions. Nest in hole in tree, cactus or cliff. Eggs 2-5; incubation 22-27 days; nestling period 53-61 days.

Movements. None certainly documented, but non-breeding wandering in search of food likely; occasional movements between La Blanquilla and Margarita have been postulated.

Status and Conservation. **VULNERABLE.** CITES I. A BirdLife "restricted-range" species. Heavily exploited everywhere for largely internal pet trade, compounded by tourist developments on the islands and other forms of habitat destruction, e.g. mining; other problems include some persecution as a crop pest and occasional island droughts. Population on mainland unknown, but a roost of 700 recorded in 1989. Margarita held 650-800 in late 1980's, rising under management to 914 in 1992. Blanquilla held under 80 in 1992. Over 400 were counted on Bonaire, 1987, this population gaining some protection within Washington-Slagbaai National Park.

Bibliography. Albornoz *et al.* (1994), Anon. (1995g), Arndt (1989), Beissinger & Snyder (1992), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Decoteau (1983), Desenne & Strahl (1991, 1994), Eddy (1995), Harrison & Holyoak (1970), van Helmond & Wijzman (1988), Jordens (1985), Low (1972, 1981, 1983a, 1994b), Mellink & Molina (1984), Meyer de Schauensee & Phelps (1978), Noegel (1983, 1986), Rebolledo (1994), Reijns & van der Salm (1981), Ridgely (1981), Rodríguez & Rojas-Suárez (1994), Rojas-Suárez (1991, 1994b, 1994c), Rooth (1968), Silvius (1989, 1991a, 1991b), Spaans (1973), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Vierheilig & Vierheilig (1988), Voous (1983, 1985), Wege & Long (1995), Whitney (1996).

320. Blue-fronted Amazon

Amazona aestiva

French: Amazone à front bleu **German:** Rotbugamazone **Spanish:** Amazona Frentiazul
Other common names: Turquoise-fronted Amazon/Parrot, Blue-fronted Parrot; Yellow-winged Amazon (*xanthopteryx*)

Taxonomy. *Psittacus aestivus* Linnaeus, 1758, southern Brazil.

Race *xanthopteryx* has occasionally been considered a separate species. Two subspecies recognized.

Subspecies and Distribution.

A. a. aestiva (Linnaeus, 1758) - E Brazil from Maranhão and Pará S to Rio Grande do Sul.

A. a. xanthopteryx (Berlepsch, 1896) - Bolivia and SW Brazil S through Paraguay to N Argentina.

Descriptive notes. 37 cm; mean 400 g. Fore-crown blue; mid-crown, face, chin and throat yellow, blue or green; hindcrown, posterior ear-coverts, sides of neck, nape and mantle green heavily edged blackish, producing scaled effect, less pronounced on wings and undersides; shoulder and speculum red, primaries tipped dark blue; tail green tipped yellowish, with lateral feathers basally barred with red. Immature has blue and yellow of head reduced. Race *xanthopteryx* has yellow shoulder, often variably intermixed with red of shoulder.

Habitat. *Cerrado* and Chaco scrub, savanna, palm groves, gallery forest, subtropical wood-

land; closely tied to old-growth areas with large trees providing nest-cavities. In winter, Argentina, occupies yungas forest, particularly stands of *Anadenanthera macrocarpa*.

Food and Feeding. Fruit or seeds of a wide variety of plants, notably (in Argentina) fruits of *Melia*, *Aspidosperma*, *Prosopis*, *Schinopsis* and *Ziziphus*, and seeds of *Citrus*, *Anadenanthera*, *Bulnesia* and *Cercidium*; also cactus fruit and palm seeds. Flowers of *Erythrina* and *Morus*, late Aug, immature fruits of *Cedrela*, Sept-Nov.

Breeding. Oct-Mar. Nest in hole in tree generally around 9 m up or, more rarely, cliff face or arboreal termitarium; preferred trees in Argentina include *Schinopsis*, *Aspidosperma*, *Chlorisia* and *Calycophyllum*. Normally 3 eggs (1-5); incubation (in captivity by female only) lasting 23-25 days; nestling period 58-60 days.

Movements. In Argentina, great majority of Chaco-nesting population moves W to eastern foothills of Andes, from mid-Mar to mid-Sept; some birds appear to wander E to E Paraguay. May-Jul.

Status and Conservation. Not globally threatened. CITES II. One of the most abundant of S. American amazons, benefiting from agriculture and despoiling maize and sunflower crops, and causing some damage to fruit (especially citrus) crops during winter. Very heavily trapped for cagebird trade, but impact on populations not clear; minimum net exports rose from 10,644 in 1981 to 58,464 in 1988, thereafter declining, most of these birds coming from Argentina, which exported 244,774 in the period 1985-1990. Selective cutting of mature *Schinopsis* trees, overgrazing by domestic livestock and oil exploration activities are all affecting parts of the Chaco in Argentina, but very substantial tracts of habitat remain.

Bibliography. Antas & Cavalcanti (1988), Balabusic *et al.* (1992), Boosey (1939), Bucher & Martella (1988), Bucher *et al.* (1992), Canevari *et al.* (1991), Contreras *et al.* (1990), Darrieu (1983a), Decoteau (1983), Eiseutraut (1935), Guix (1995), Hall & Fryer (1994), Hayes (1995), Inskipp & Corrigan (1992), Inskipp *et al.* (1988), Lantermann (1993), Low (1972), Mosa *et al.* (1992), Nores & Yzurieta (1994), Núñez *et al.* (1991), Olmos (1993), Orfila (1938), de la Peña (1988), Pereira (1995), Pinto (1946), Remsen & T aylor (1989), Ridgely (1981), do Rosário (1996), Samuelson (1994), Saud, Garrido & Mosa (1991), Saud, Núñez, Garrido, Cálzon & Chorolque (1991), Saud, Núñez, Garrido, Mosa *et al.* (1991), Schmutz & Prus (1987), Short (1975), Sick (1985, 1993), Smith (1942), Steinbacher (1962), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Wetmore (1926), Whitney (1996).

321. Yellow-crowned Amazon

Amazona ochrocephala

French: Amazone à front jaune **German:** Gelbscheitelamazone **Spanish:** Amazona Real
Other common names: Yellow-fronted Amazon/Parrot, Yellow-crowned Parrot; Yellow-headed Amazon (*oratrix* group); Yellow-naped Amazon (*auropalliata* group)

Taxonomy. *Psittacus ochrocephalus* J. F. Gmelin, 1788, Venezuela.

Polytypic and, in Central America, apparently polymorphic. Often broken down into three species: *A. oratrix*, incorporating *tresmariae* and *belizensis*; *A. auropalliata*, incorporating *caribaea* and *parvipes*; and *A. ochrocephala* incorporating *panamensis*, *xantholaema* and *nattereri*. However, considerable variation and overlap in characters exist in populations in and adjacent to Honduras, such that no very coherent species limits can be set at any point between *oratrix* to the N and *panamensis* to the S; possibly the clearest-cut step would involve separating *oratrix* and *tresmariae*, thus transferring *belizensis* to the *ochrocephala* group. On present knowledge, entire complex is probably best regarded as a single species. Patterns of variation remain unclear and birds of extreme E Guatemala may be separable as race *guatemalensis* and those of NW Honduras as *hondurensis*; both of these forms appear closer to *oratrix* group than to *auropalliata* group. Ten subspecies currently recognized.

Subspecies and Distribution.

A. o. tresmariae Nelson, 1900 - Tres Marias Is. off WC Mexico.

A. o. oratrix Ridgway, 1887 - Pacific and Atlantic lowlands of Mexico.

A. o. belizensis Monroe & Howell, 1966 - Belize.

A. o. caribaea Lousada, 1989 - Bay Is, Honduras.

A. o. parvipes Monroe & Howell, 1966 - NE Honduras and N Nicaragua.

A. o. auropalliata (Lesson, 1842) - S Mexico S to NW Costa Rica.

A. o. panamensis (Cabanis, 1874) - W Panama to NW Colombia.

A. o. ochrocephala (J. F. Gmelin, 1788) - E Colombia E through Venezuela, Trinidad and the Guianas to NC Brazil (Pará).

On following pages: 322. Orange-winged Amazon (*Amazona amazonica*); 323. Scaly-naped Amazon (*Amazona mercenaria*); 324. White-faced Amazon (*Amazona kawalli*); 325. Mealy Amazon (*Amazona farinosa*); 326. Vinaceous Amazon (*Amazona vinacea*); 327. St Lucia Amazon (*Amazona versicolor*); 328. Red-necked Amazon (*Amazona arausiaca*); 329. St Vincent Amazon (*Amazona guildingii*); 330. Imperial Amazon (*Amazona imperialis*); 331. Red-fan Parrot (*Deroptyus accipitrinus*); 332. Blue-bellied Parrot (*Triclaria malachitacea*).

A. o. xantholaema Berlepsch, 1913 - Marajó I, Amazon Delta, N Brazil.

A. o. nattereri (Finsch, 1865) - S Colombia S through E Ecuador and E Peru to N Bolivia and W Brazil. Feral populations (*oratrix*) in California, Florida and Puerto Rico.

Descriptive notes. 35-38 cm; 340-535 g. Green, more yellowish below; forehead and mid-crown yellow, often with some yellow round eye; cheeks and ear-coverts bright green; hindcrown to mantle green very lightly edged blackish; bend of wing red, carpal edge yellowish, speculum red, flight-feathers tipped dark blue; tail tipped yellow and basally marked red on outer feathers. Immature duller, with less yellow and red on head and wing. In N populations, adult plumage appears to develop more yellow with age. Subspecies show small but usually distinctive variations in distribution of yellow on head, culminating in N

with entirely yellow-headed races *oratrix* and *tresmariae*.

Habitat. Tropical deciduous woodland, tall thorn scrub, humid gallery forest, seasonally flooded (*várzea*) forest and secondary riverine growth, mangroves, pine savanna, *Mauritia* palm stands in wetter open areas, llanos, cultivated land with remnant groves and woodlots, and even some suburban areas, always in lowlands.

Food and Feeding. Fruit and/or seeds and flowers of trees such as *Pithecellobium* (whose beans are a winter staple in NE Mexico), *Acacia*, *Macuna*, *Zuelania*, *Bumelia*, *Solanum*, *Tabebuia*, *Erythrina*, *Ficus*, *Cochlospermum*, *Curatella*, *Terminalia* and *Euterpe* and other palms. Flocks also take cultivated crops such as maize, green bananas, mangoes, lemons, avocados and lucerne (this last implying feeding on ground).

Breeding. Feb-May in Mexico and NE Venezuela; Dec-Jan in Colombia; Jan in Surinam. Nest in hollow in tree, often in dead wood including palm stub, generally 4-15 m up but sometimes lower; also in terrarium. Eggs 2-3; incubation 25-26 days.

Movements. Year-round resident in Mexico, and this probably true throughout range; however, some birds appear to wander in response to local food shortages, and occasional flocks of considerable size form.

Status and Conservation. Not globally threatened. CITES II. The distinctive yellow-headed populations of *oratrix* in Mexico and, more recently, of *belizensis* in Belize are, however, very seriously threatened by combination of habitat loss and intensive trapping (this bird being a renowned "talker" as well as most attractive). The populations of proposed races *guatemalensis* and *hondurensis* are both highly threatened (despite the latter's presence inside Punta Sal National Park) and number in the low hundreds, and race *caribaea* likewise probably 100-200. Honduran population of *parvipes* estimated at c. 140,000 birds. Locally quite common in Panama and local in Colombia. Venezuelan population in steep decline owing to conversion of llanos and intensive trapping. However, the species remains extremely common in other parts of its range, e.g. SE Peru (present in Manu National Park, where density reaches 0.5 pairs/km²) and NC Brazil (Roraima). Rare on Trinidad.

Bibliography. Anon. (1993), Arman & Arman (1980, 1981), Binford (1989), Bosch (1991b), Chapman *et al.* (1989), Clinton-Eitnir (1990, 1996), Collar (1996), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Decoteau (1983), Desenne (1994), Desenne & Strahl (1991, 1994), Dolton (1994), Enkerlin-Hoflich (1995), Freud (1980b, 1991b), Gildardo (1976), González (1995a, 1995b), Hansen (1984), Haverschmidt & Mees (1994), Hilty & Brown (1986), Howell & Webb (1995a), Inskipp & Corriga (1992), Inskipp *et al.* (1988), Lever (1987), Lousada (1989), Lousada & Howell (1996), Low (1972), Lowery & Dalquest (1951), McLoughlin & Burton (1970), Meyer de Schauensee & Phelps (1978), Monroe (1968), Monroe & Howell (1966), O'Neill (1981), Parkes (1990a), Pérez & Eguarte (1989), Pfeffer (1988b), Pulido (1991), Ridgely (1981), Ridgely & Gwynne (1989), Samuelson (1994), Schaldach (1963), Scheid (1992), Schindlinger (1996), Sick (1985, 1993), Silva (1993a), Slud (1964), Smith (1970), Snyder (1966), Stiles & Skutch (1989), Stoodley, J. & Stoodley (1990), Stoodley, P. & Stoodley (1983), Stotz *et al.* (1996), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Thurber *et al.* (1987), Toft & Brice (1993), Tostain *et al.* (1992), Wege & Long (1995), Wetmore (1939, 1968), Whitney (1996), Wiedenfeld (1993).

322. Orange-winged Amazon

Amazona amazonica

French: Amazone aourou **German:** Venezuelaamazone **Spanish:** Amazona Alinaranja
Other common names: Orange-winged Parrot

Taxonomy. *Psittacus amazonicus* Linnaeus, 1766, Surinam; error = "le pays des Amazones".

Validity of proposed race *tobagensis* of Trinidad and Tobago highly dubious, as differences probably attributable to individual variation. Monotypic.

Distribution. N & E Colombia, E Ecuador, E Peru and N Bolivia E through Venezuela, Trinidad and Tobago, the Guianas and the Amazon basin to N & E Brazil.

Descriptive notes. 31 cm; 298-469 g. Yellow forehead and area from base of bill to below eye, separated by blue stripe from lores over and behind eye; rest of head blue-green shading to green on rest of body; carpal edge yellow; orange-red speculum; tail green tipped yellowish, lateral feathers tinged orange-red with a central dark green bar, outermost edged blue. Immature similar to adult.

Habitat. Lowlands, rarely above 600 m, occurring in virtually every habitat in its range where tall trees are present except humid *terra firme* forest (where *A. farinosa* the dominant amazon); thus in *várzea* and second growth

along rivers, gallery forest, rain forest margins and clearings, mangroves, deciduous woodland, savanna and more open areas with *Mauritia* palm groves, parklands and even gardens; large numbers seen roosting in giant bamboo.

Food and Feeding. Little studied, with only a few plant species identified, such as *Erythrina*, *Sloanea*, *Richeria*, *Byrsionima*, *Curatella americana*, *Tabebuia serratifolia*, palms *Euterpe*, hog plum *Spondias mombin*, but propensity for cultivated crops (oranges, mangoes, cocoa) suggests adaptability to many local food sources.

Breeding. Jan-Jun on Trinidad; Mar-Jun in NE Venezuela; Feb-Mar in Surinam; Dec-Feb in Colombia. Nest in hole in tree, including mangroves in Surinam, cabbage palm stumps in Trinidad. Eggs 2-5; incubation, by female only, lasting around 3 weeks; nestling period around 2 months.

Movements. None is recorded.

Status and Conservation. Not globally threatened. CITES II. Abundant throughout much of extensive range, in many places, notably in N of range, the commonest large parrot, and classified as a pest on Trinidad and Tobago. Deforestation has caused some declines in E Brazil, and "sport" hunting has reduced numbers in Surinam; hunting in French Guiana is excessive. Very heavily trapped in parts of range, with Guyana the source of the great majority of birds in international trade (66,615 in years 1981-1985), but with probably high levels of domestic consumption also, e.g. in Venezuela.

Bibliography. Decoteau (1983), Desenne & Strahl (1991, 1994), French (1991), Freud (1993a), Friedmann (1948b), Hadgkiss & Mitchell (1983a), Haverschmidt & Mees (1994), Hilty & Brown (1986), Inskipp *et al.* (1988), Lever (1987), Low (1972), McLoughlin & Burton (1970), Meyer de Schauensee & Phelps (1978), Millam *et al.* (1995), Niles (1981), Nottebohm & Nottebohm (1969), O'Neill (1981), Ott (1982), Parker *et al.* (1982), Pinto (1946, 1964), Ridgely (1981), da Rocha *et al.* (1988), Schubart *et al.* (1965), Sick (1985, 1993), Snyder (1966), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Tostain *et al.* (1992), Whitney (1996), Williams (1992).

323. Scaly-naped Amazon

Amazona mercenaria

French: Amazone mercenaire **German:** Soldatenamazone **Spanish:** Amazona Mercenaria
Other common names: Scaly-naped Parrot

Taxonomy. *Psittacus mercenarius* Tschudi, 1844, Peru.

Two subspecies recognized.

Subspecies and Distribution.

A. m. canipalliata (Cabanis, 1874) - Andes of Venezuela, Colombia and Ecuador.

A. m. mercenaria (Tschudi, 1844) - Andes of Peru and Bolivia; one record from Argentina.

Descriptive notes. 33-34 cm; 340 g. Mainly green, darker above, hindcrown, nape and mantle with dark edges to feathers giving slight scaled effect; small whitish bare orbital ring; tail-coverts yellowish green; carpal edge yellowish with some orange-red; speculum red; flight-feathers tipped dark blue; tail green tipped yellowish, lateral feathers with broad red subterminal bar. Immatures undescribed. Race *canipalliata* lacks red speculum.

Habitat. Subtropical and temperate cloud forest and other montane formations, often in broken, part-open country with ravines, ridgetops and clearings. Generally 1500-3000 m, but as

low as 800 m in E Andes of Peru and Bolivia, and up to treeline at 3600 m in Colombia.

Food and Feeding. Apparently no information.

Breeding. Mar-May in Colombia. Nest and eggs undescribed. Incubation 25-26 days.

Movements. Some seasonal elevational movement or semi-nomadism noted in W Andes of Colombia; probably true throughout range, as suggested by formation of large roosts in non-breeding season, Bolivia, and by observations of birds flying very high at one site in SW Ecuador.

Status and Conservation. Not globally threatened. CITES II. Generally a low-density species and nowhere common; has suffered from deforestation in N of range, notably in Colombia, although still common on Santa Marta massif and resident in Cueva de los Guácharos National Park; highly threatened by habitat loss within restricted range, Venezuela. Little traded owing to confinement to montane forest and low densities.

Bibliography. Bond & Meyer de Schauensee (1943), Butler (1979), Carriker (1959), Darlington (1931), Decoteau (1983), Desenne & Strahl (1991, 1994), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Low (1972), Meyer de Schauensee & Phelps (1978), Nore & Yzurieta (1994), O'Neill (1981), Remsen & T aylor (1989), Ridgely (1981), Ridgely & Gaulin (1980), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Todd & Carriker (1922), Walker & Jacobs (1995), Whitney (1996).

324. White-faced Amazon

Amazona kawalli

French: Amazone de Kawall **German:** Kawallamazone **Spanish:** Amazona de Kawall
Other common names: Kawall's Parrot

Taxonomy. *Amazona kawalli* Grantsau and Camargo, 1989, Mato Piri, right bank of Rio Juruá below Eirunepé, Amazonas, Brazil.

Taxonomic status of this recently described form was questioned, and it was widely considered to be an aberrant form of *A. farinosa*, but scrutiny of further evidence has convincingly shown it to be a valid species. Monotypic.

Distribution. Amazon basin, Brazil.

Descriptive notes. 35-36 cm. Very close to *A. farinosa* but with narrow white strip of bare skin bordering base of bill, and periorbital ring mid-grey; tail shorter with correspondingly reduced yellowish terminal band, with scarlet and some blue on basal half of outermost tail feathers; also lacks red on leading edge of wing (sympatric *A. farinosa* possess this) and the floury glaucous tone to the upperparts, except the mantle, which gives *A. farinosa* its name. Immature undescribed.

Habitat. Tropical lowland forest, possibly associated with watercourses.

Food and Feeding. No information.

Breeding. No information.

Movements. No information.

Status and Conservation. Not globally threatened. CITES II. Very recently discovered, and still known only from three wild-caught museum skins and a few captive birds, but the general evidence, particularly the wide range over which records are distributed, indicates this is an uncommon but cryptic species with no serious current threats. Captive bird found in 1996 on edge of Amazonas National Park, suggesting presence there.

Bibliography. Anon. (1991), Bosch (1991a), Collar & Pittman (1996), Decoteau (1983), Forgach (1996), Forrester (1993), Grantsau & Camargo (1989, 1990), Kawai (1997), Low (1990a), Pittman (1997a), Stotz *et al.* (1996), Stresemann (1924a), Vuilleumier *et al.* (1992), Wheatley (1994), Whitney (1996).

325. Mealy Amazon
Amazona farinosa

French: Amazone poudrée **German:** Mülleramazone **Spanish:** Amazona Harinosa
Other common names: Mealy/Blue-crowned Parrot

Taxonomy. *Psittacus farinosus* Boddaert, 1783, Cayenne.
Proposed South American races *chapmani* and *inornata* appear to lack consistent features. Three subspecies currently recognized.
Subspecies and Distribution.
A. f. guatemalae (P. L. Sclater, 1860) - SE Mexico to NW Honduras.
A. f. virenticeps (Salvadori, 1891) - Sula Valley, Honduras, to W Panama.
A. f. farinosa (Boddaert, 1783) - E Panama and E, N & W Colombia E to SC Venezuela and the Guianas, and S through NW & E Ecuador, E Peru and NE Bolivia to Amazon basin, then on to CE & SE Brazil.

Descriptive notes. 38-43 cm; 535-766 g. Generally dull green, with hindcrown, nape and upperparts suffused floury glaucous, face and underparts paler; large white bare orbital ring; forehead to mid-crown variably yellow (sometimes full, patchy or absent), hindcrown and nape edged dark, giving scaled effect; wing with red to orange carpal edge, red speculum and dark blue tips to flight-feathers; tail green with very broad yellowish green terminal band. Immature similar. Race *virenticeps* has yellowish green carpal edge and bluish green crown; *guatemalae* is similar but with much bluer crown.

Habitat. Extensive tracts of lowland tropical evergreen forest usually on dry ground, sometimes (perhaps seasonally) also in stands of *Mauritia* palms, deciduous and gallery woodland, sand-ridge forest, semi-open and tall second growth near forest; occasionally reaches to 1500 m in N & W of range, but generally below 500 m.
Food and Feeding. Seeds and/or fruit of palms *Euterpe*, figs, *Brosimum*, *Inga*, *Dussia*, *Eschweilera*, *Pithecellobium*, *Tetragastris*, *Dialium guianensis*, *Peritassa compta*, *Prionostemma aspera*, *Cochlospermum orinocense*, *Sloanea grandiflora*, *Corina macrocarpa*, *Abuta grandifolia*, *Piptadenia psilostachya*, *Cecropia miparia*, *Helicostylis tomentosa*, *Micropholis*, *Pouteria*; also buds and flowers, arils of *Casearia* and *Virola*, and nectar of *Tabebuia insignis*.
Breeding. Apr-May in Guatemala; Nov-Feb in SC Brazil. Nest in hole in tree, 3-30 m up, also once in crevice in stone wall. Eggs 3; incubation 26-27 days.
Movements. Found to increase in numbers in sand-ridge forests of coastal Surinam, Jul-Aug; wanders into mountains, NW Colombia, Oct-Jan, and is most numerous in far SE, Jun-Oct. Considered a permanent resident, Oaxaca, Mexico.
Status and Conservation. Not globally threatened. CITES II. Large populations survive in the less disturbed parts of its extensive range, but has suffered from forest destruction in Central America, W Ecuador and SE Brazil, and is heavily hunted for food in French Guiana; trade is generally moderate, heavy in some countries. Present in Manu National Park, Peru, where density reaches 2 pairs/km²; common on Cerro Pirre, Darién National Park, Panama, and in Tikal National Park, Guatemala.
Bibliography. Binford (1989), Burkhart (1985), Collar & Pittman (1996), Decoteau (1983), Desenne (1994), Desenne & Strahl (1991, 1994), Friedmann (1948b), González-García (1993), Haverschmidt & Mees (1994), Higgins (1979), Hilty & Brown (1986), Howell & Webb (1995a), Inskipp *et al.* (1988), Lantermann (1990), Low (1972), McLoughlin & Burton (1970), Meyer de Schauensee & Phelps (1978), Monroe (1968), O'Neill (1981), Paynter (1955), Ridgely (1981), Ridgely & Gwynne (1989), Sick (1985, 1993), Slud (1964), Snyder (1966), Stiles & Skutch (1989), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Tostain *et al.* (1992), Wetmore (1957, 1968), Whitney (1996), Woodbury (1992).

326. Vinaceous Amazon
Amazona vinacea

French: Amazone vineuse **German:** Taubenhalsamazone **Spanish:** Amazona Vinosa
Other common names: Vinaceous/Vinaceous-breasted Parrot

Taxonomy. *Psittacus vinaceus* Kuhl, 1820, Brazil. Monotypic.
Distribution. E Brazil from Bahia S to E Paraguay and N Argentina.

Descriptive notes. 30 cm. Lores and frontal band red; rest of head green with dark edging on crown feathers, giving scaled effect, more pronounced on nape and sides of neck, where feathers pale blue, and breast and belly, where feathers purple; back and wings dark green, with red and yellow carpal area, red speculum and turquoise on outer webs of blue-tipped primaries; tail green with narrow yellow terminal band and basal dull red on outer feathers. Immature has reduced red lores, green in breast, yellowish carpal area.
Habitat. Associated closely with forest dominated by *Araucaria angustifolia* at least in S of range, possibly in N also, but degree of dependence unclear. Also reported present in epiphyte- and bamboo-rich humid forest, young second growth, pinewoods and woodlots in cleared areas.
Food and Feeding. *Araucaria* nuts and possibly other cone-crops much exploited, but also buds, berries, fruits, flowers and young eucalyptus and pine leaves, with *Euterpe edulis* fruits and chewing *Guadua* bamboo shoots and leaves noted; formerly caused damage to orange orchards.
Breeding. Sept-Dec in Argentina and Paraguay, rather later in Brazil, with some evidence that delayed breeding by some pairs may relate to need to use already occupied nest-sites. Nest is a hole

in a tree, mostly *Araucaria*, of which many places now lack specimens of sufficient size. Eggs 2-4; incubation 25-26 days; nestling period c. 70 days.

Movements. Unclear, but when formerly abundant considerable invasions of Paraguay occurred at times. In Rio Grande do Sul some post-breeding dispersal occurs, with many birds disappearing in Jan and all in Mar, returning in Apr and present for rest of year. Annual variations in *Araucaria* or other cone-crop production would cause dispersive, nomadic behaviour.

Status and Conservation. ENDANGERED. CITES I. Now rare virtually everywhere within its substantial range, and nowhere numerous. Common to abundant in the nineteenth century, deforestation has caused a long-term decline in the past 100 years, and clearance of large tracts of *Araucaria* (2100 km² in Misiones, Argentina, in 1960 reduced to two patches totalling 5 km² by 1988) has doubtless been most damaging. International trade has never been large, but trapping for domestic markets appears to have been heavy over many decades. Protected areas where the species occurs in some numbers, none of which seems likely to provide year-round needs, include Caratinga (Minas Gerais), Campos do Jordão and Jacupiranga State Parks (São Paulo), Lauréas State Park (Paraná), São Joaquim National Park (Santa Catarina), Espigão Alto State Park, Serra Geral and Aparados da Serra National Parks (Rio Grande do Sul), Brazil; Itabó Nature Reserve, Itabó and Limoy Biological Reserves and Tatí Yupí Biological Refuge, Paraguay; and Araucaria Provincial Park, Argentina.

Bibliography. Aleixo & Galetti (1997), Beissinger & Snyder (1992), Belton (1984), Bertagnolio (1981), Boçon (1994), Brooks *et al.* (1993), Canevari *et al.* (1991), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Decoteau (1983), Hayes (1995), López (1992), Low (1972), Lowen *et al.* (1996), Navas & Bó (1988), Nores & Yzurieta (1994), de la Peña (1988), Pinto (1938), Ridgely (1981), do Rosário (1996), Scott & Brooke (1985), Sick (1972, 1985, 1993), Sick & Teixeira (1979), Silva (1991b), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Sweeney (1997d), Wege & Long (1995), Whitney (1996), Willis & Oniki (1981).

327. St Lucia Amazon
Amazona versicolor

French: Amazone de Sainte-Lucie **German:** Blaustirnamazone **Spanish:** Amazona de Santa Lucía
Other common names: St Lucia Parrot

Taxonomy. *Psittacus versicolor* P. L. S. Müller, 1776, Havana; error = St Lucia. Forms a superspecies with *A. arausiaca*. Monotypic.
Distribution. St Lucia (Lesser Antilles).

Descriptive notes. 43 cm. Royal blue forehead and lores shading paler on mid-crown and face, becoming scaled green on hindcrown, nape, sides of neck and mantle; red patch on upper breast with green and maroon mottling on lower breast and maroon on belly; vent greenish yellow; wings green with red speculum and dark blue primaries; tail green tipped yellowish. Immature undescribed.
Habitat. Tropical moist forest, now all in montane interior.
Food and Feeding. Fruits and/or seeds of *Clusia*, *Talauma*, *Pouteria*, *Miconia*, *Manilkara*, *Byrsonima*, *Sloanea*, *Pithecellobium*, *Dacryodes*,

Cassipourea, *Protium*, *Torrubia*, *Pterocarpus*, *Sterculia* and several palms.
Breeding. Feb-Mar or later. Nest in hole in tree. Eggs 2; in captivity, incubation 28 days, nestling period c. 81 days.
Movements. None reported.
Status and Conservation. VULNERABLE. CITES I. A BirdLife "restricted-range" species. Formerly common, but only 1000 birds estimated around 1950 and a steady decline thereafter as combination of habitat loss, hunting (for food), trade and hurricanes continued to reduce numbers. Major conservation endeavours from late 1970's, when possibly only 150 birds remained, resulted in strong national and popular support for species, whose numbers by 1990 were 300-350.
Bibliography. Anon. (1983, 1988), Beissinger & Snyder (1992), Bond (1985), Butler (1981, 1987, 1991, 1992), Christian, Lacher *et al.* (1996), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Copsey (1995), Decoteau (1983), Diamond (1973), Fidgett & Robert (1993), Hoppe (1997a, 1997b), Jeggo (1976a, 1976b, 1981, 1983, 1987, 1991), Jeggo & Anthony (1991), Jeggo & Taynton (1981), Jeggo, Anthony & John (1989), Jeggo, Taynton & Bobb (1983), Jovicich (1976), Keith (1997), Kepler (1973), King (1978/79), Low (1972, 1980b, 1987c, 1994b), Mühlhaus & Mühlhaus (1983), Nichols (1976, 1977), Silva (1980b), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Whitney (1996), Wingate (1969).

328. Red-necked Amazon
Amazona arausiaca

French: Amazone de Bouquet **German:** Blaukopfamazone **Spanish:** Amazona Gorgirroja
Other common names: Red-necked Parrot

Taxonomy. *Psittacus arausiacus* P. L. S. Müller, 1776, Dominica. Forms a superspecies with *A. versicolor*. Monotypic.
Distribution. Dominica (Lesser Antilles).

Descriptive notes. 40 cm. Similar to *A. versicolor* but with no dark edges to feathers giving scaled effect, and with red on upper breast reduced to throat spot; speculum red and yellow; primaries tipped blue-black. Immature undescribed.
Habitat. Moist forest chiefly at 300-800 m, sometimes ranging into more open cultivated areas.
Food and Feeding. Wide range of fruits and/or seeds recorded, including *Dacryodes*, *Licania*, *Richeria*, *Amanoa*, *Simarouba*, *Symphonia*, *Cordia*, *Pithecellobium*, *Byrsonima*, *Anacardium*, *Pouteria*, *Dussia*, *Ormosia* and palms, sometimes

also wild guava and cultivated citrus.

Breeding. Feb-Jun. Nest in hole in tree, often *Dacryodes excelsa* and *Sloanea berteriana*. Eggs 2. **Movements.** Formerly descended to N coastal area, Aug-Oct, and still rather nomadic, Nov-Jan.

Status and Conservation. VULNERABLE. CITES I. A BirdLife "restricted-range" species. Conflicting reports of former abundance; by early 1970's probably less than 400, owing to habitat loss, hunting (for food) and trade. Two hurricanes, 1979 and 1980, possibly halved population. Natural recovery and considerable conservation effort since that time has resulted in 500-1000 birds currently.

Bibliography. Amberger (1989), Anon. (1983), Beissinger & Snyder (1992), Bond (1928b, 1941, 1985), Butler (1989, 1992), Christian, James & Charles (1994), Christian, Lacher *et al.* (1996), Christian, Zamore & Christian (1994), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Decoteau (1983), Evans, P.G.H. (1988, 1991, 1994), Gochfeld (1974), Gregoire (1981), Howes (1929), Kepler (1973), King (1978/79), Low (1972, 1987c, 1994b), Nichols (1976, 1977), Nichols *et al.* (1976), Snyder & Snyder (1979), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Swank & Julien (1975), Whitney (1996).

329. St Vincent Amazon

Amazona guildingii

French: Amazone de Saint-Vincent

Spanish: Amazona de San Vicente

German: Königsamazone

Other common names: St Vincent Parrot

Taxonomy. *Psittacus Guildingii* Vigors, 1837. St Vincent. Monotypic.

Distribution. St Vincent (Lesser Antilles).

Descriptive notes. 40 cm. Two morphs. Commoner yellow-brown morph, itself variable, has head white shading to yellowish orange on hindcrown, cheeks and chin, with bluish patch behind eye and blue-grey "scaled" nape, shading to scaled bronze upperparts and breast, becoming greenish yellow on vent; wing-coverts orange and red, primaries black with yellow bases, secondaries deep blue with orange bases; tail deep blue with broad yellow terminal band and orange at base. Immature similar but duller. Green morph tends to lack much of orange, with dull green upperparts and whitish blue face.

Habitat. Mature moist forest, with some preference for lower elevations where larger trees and hence more nest-sites exist, occasionally wandering into cultivated areas.

Food and Feeding. Fruit and/or seeds of *Pouteria* and *Dacryodes* especially, also *Cordia*, *Krugiodendron*, *Micropholis*, *Dussia*, *Talauma*, *Inga*, *Chione*, *Simaruba*, *Ixora*, *Sloanea*, *Richeria*, *Psidium*, *Annona*, *Calophyllum*, *Andira*, *Alphanes*, *Cecropia*, *Meliosma*, various palms and figs.

Breeding. Jan-Jul, mostly Apr-May. Nest in holes in trees, chiefly *Dacryodes*, sometimes close together. Eggs 2, rarely 3; in captivity, incubation c. 24 days, nestling period 67-69 days.

Movements. None recorded.

Status and Conservation. VULNERABLE. CITES I. A BirdLife "restricted-range" species. Formerly common, but up to the early 1980's suffered from the combined effects of habitat destruction, trade, hunting (for food), hurricanes and eruptions. With increasing conservation activity thereafter, censuses have suggested a steady population increase, from 370-470 in 1982, 440-500 in 1988, to around 800 in 1994. Considerable effort has been given to habitat conservation, law enforcement and public awareness in past 15 years, so that both the amazon and its habitat are currently relatively secure. There is a 44 km² St Vincent Parrot Reserve in the centre of the island.

Bibliography. Allen (1961), Andrie & Andrie (1975), Anon. (1983), Beissinger & Snyder (1992), Berry (1974, 1981), Bond (1985), Butler (1988, 1990, 1992), Christian (1993), Christian, Lacher *et al.* (1996), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Decoteau (1983), DeFreitas (1990), Forshaw (1997), Gochfeld (1974), Greenwood (1994), Harrison & Holyoak (1970), Jeggo (1981, 1991), Kepler (1973), King (1978/79), Laidler (1977), Lambert (1983, 1985), Low (1972, 1987c, 1994b), Nichols, H.A.J. (1974, 1975, 1976), Nichols, H.A.J. & Nichols (1973), Nichols, T.D. (1981b), Noegel *et al.* (1991), Robiller & Trogisch (1985b), Silva (1989b), Snyder *et al.* (1987), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Whitney (1996).

330. Imperial Amazon

Amazona imperialis

French: Amazone impériale

German: Kaiseramazone

Spanish: Amazona Imperial

Other common names: Imperial Parrot

Taxonomy. *Amazona imperialis* Richmond, 1899, Dominica. Monotypic.

Distribution. Dominica (Lesser Antilles).

Descriptive notes. 45 cm. Head, nape and mantle purplish black, shading to purple with dark margins giving a scaled effect on undersides; thighs and vent dull green; wings dull green with red carpals, purple speculum and blackish blue primaries; tail reddish brown tipped greenish blue. Immature has green nape and neck.

Habitat. Moist forest chiefly at 600-1300 m.

Food and Feeding. Wide range of fruits and/or seeds recorded, including *Dacryodes*, *Licania*, *Richeria*, *Amanoa*, *Simarouba*, *Symphonia*, *Pouteria*, *Tapura*, *Clusia* and several palms.

Breeding. Feb-Jun. Nest in hole in tree, notably *Dacryodes excelsa* and *Sloanea berteriana*. Eggs 2, though seldom more than 1 young reared.

Movements. Sedentary.

Status and Conservation. VULNERABLE. CITES I. A BirdLife "restricted-range" species. Formerly common to abundant within relatively small, inaccessible range, declining catastrophically

in the period 1880-1980 owing to habitat destruction, extensive hunting for food, trade and hurricanes, two of the latter in 1979 and 1980 reducing the population to 40-100. Natural recovery and considerable conservation effort since that time has resulted in some upturn, with 80-100 in 1993 and higher numbers judged present in 1994.

Bibliography. Amberger (1989), Anon. (1983), Beissinger & Snyder (1992), Bond (1928b, 1941, 1985), Butler (1989, 1992), Christian, James & Charles (1994), Christian, Lacher *et al.* (1996), Christian, Zamore & Christian (1994), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Decoteau (1983), Evans, P.G.H. (1988, 1991, 1994), Gochfeld (1974), Gregoire (1981), Harrison & Holyoak (1970), Kepler (1973), King (1978/79), Low (1972, 1987c, 1994b), Nichols, H.A.J. (1976, 1977), Nichols, H.A.J. *et al.* (1976), Nichols, T.D. (1981c, 1986), Snyder & Snyder (1979), Stoodley & Stoodley (1990), Stotz *et al.* (1996), Swank & Julien (1975), Whitney (1996), Wood (1924a).

Genus *DEROPTYUS* Wagler, 1832

331. Red-fan Parrot

Deroptyus accipitrinus

French: Papegai maillé

German: Fächerpapagei

Spanish: Loro Cacique

Other common names: Hawk-headed Parrot

Taxonomy. *Psittacus accipitrinus* Linnaeus, 1758, India; error = Cayenne.

Races may be better regarded as constituting a parapatric species pair. Two subspecies currently recognized.

Subspecies and Distribution.

D. a. accipitrinus (Linnaeus, 1758) - SE Colombia, E Ecuador and NE Peru to Venezuela, the Guianas and Brazil N of Amazon (to Amapá).

D. a. fuscifrons Hellmayr, 1905 - Brazil S of Amazon from upper R Madeira, Rondônia and N Mato Grosso E to Maranhão; possibly also N Bolivia.

Descriptive notes. 35-36 cm; 190-300 g. Forehead and crown above eye white; face, cheeks and throat brown with buff shaft streaks, also some feathers backing mid-crown; hindcrown, elongated nape feathers, sides of neck, breast and belly maroon edged light blue; back, wings, thighs and undertail-coverts dull green; primaries and underside of tail blackish; upper tail green edged blue, with concealed maroon spot at base of inner web. Immature has less white on forehead. Race *fuscifrons* has forehead and crown dusky brown with whitish shaft streaks, no maroon spot on tail.

Habitat. Undisturbed *terra firme* forest, sometimes apparently avoiding *várzea*, edge and clearings; however, also recorded in coastal sand-ridge and savanna forests, although in Venezuela mostly feeding in riverine habitats.

Food and Feeding. Small understorey fruits, hard fruits of various palms such as *Attalea*, *Astrocaryum*, *Euterpe* and *Jessenia*, flowers, petioles of leaves, buds and shoots of *Bombacopsis*, leaves of *Spondias mombin*, seeds of *Jacaranda copeia*, *Caraipa densiflora*, *Licaria alba*, pulp and seeds of *Tetragastris*, fruit of *Ocotea globifera* and *Dialium guianense* and also cultivated guava (*Psidium*) and *Inga* fruit.

Breeding. Dec and Feb in Brazil; Jan-Apr in the Guianas; Feb-Jun in Venezuela, but with courtship and copulation witnessed in Aug. Nest in holes in trees, also stumps. In captivity: 2-3 eggs; incubation 28 days; nestling period 9 weeks. In the wild, the only two nests whose contents were determined held a chick each.

Movements. Some local displacements may occur as abundance fluctuates seasonally in certain areas.

Status and Conservation. Not globally threatened. CITES II. Nominate *accipitrinus* common in NE of range, less so in W, and known by a single record in Ecuador; little threatened by habitat loss, though in E under pressure, and in W possibly overtrapped locally; present in several large national parks and reserves. Race *fuscifrons* has perhaps suffered more from habitat loss and occurs in no protected area, but common on Rio Jiparaná in Rondônia.

Bibliography. Anon. (1993), Decoteau (1983), Descortils (1983), Desenne (1994), Desenne & Strahl (1991, 1994), Forrester (1993), Haverschmidt & Mees (1994), Hilty & Brown (1986), Howard (1972), Inskipp *et al.* (1988), Joseph (1988a), Lehmann (1957), Low (1972, 1997f), McLoughlin & Burton (1976), Meyer de Schauensee & Phelps (1978), O'Neill (1981), Oniki & Willis (1982), Penard (1927), Ridgely (1981), Santos (1991), Schubart *et al.* (1965), Sick (1985, 1993), Snyder (1966), Stotz *et al.* (1996), Strahl *et al.* (1991), Thiollay (1991), Tostain *et al.* (1992), Whitney (1996).

Genus *TRICLARIA* Wagler, 1832

332. Blue-bellied Parrot

Triclaria malachitacea

French: Crick à ventre bleu

German: Blaubauchpapagei

Spanish: Loro Ventriazul

Other common names: Purple-bellied Parrot

Taxonomy. *Psittacus malachitaceus* Spix, 1824, Rio de Janeiro. Monotypic.

Distribution. SE Brazil from Bahia to Rio Grande do Sul; two records from Misiones, Argentina.

Descriptive notes. 28 cm; 110-155 g. Green throughout, except for deep blue patch from lower breast to abdomen, bluish green in flight and tail feathers, and whitish bill and periocular region. Female lacks blue on belly. Immature like female, though male shows some blue on belly.

Habitat. Lower montane and escarpment humid broadleaf Atlantic forest, 300-1000 m, usually being found in the canopy of tall, bromeliad-rich forest along watercourses in valleys, but entering lowland forest and sometimes plantations, orchards and even suburban woodlands.

Food and Feeding. In Rio Grande do Sul, seeds and pulp of many native plants, notably from Euphorbiaceae, such as *Pachystroma longifolium*, *Actinostemon concolor* and *Sebastiania brasiliensis*, and, in the understorey, Myrtaceae, mainly *Eugenia rostrifolia* and *Campomanesia xanthocarpa*,

plus cultivated maize. Elsewhere fruits, including epiphytic cacti, seeds of *Psidium*, araucaria nuts, flowers of *Aechmea ornata*, nectar, buds and perhaps insects, birds also venturing into orchards to take oranges and jabuticaba fruit or seeds. Captive birds also seen to take bark, leaves, algae growing on wood. Reported penchant for fruits of the palm *Euterpe edulis* now known to be untrue.

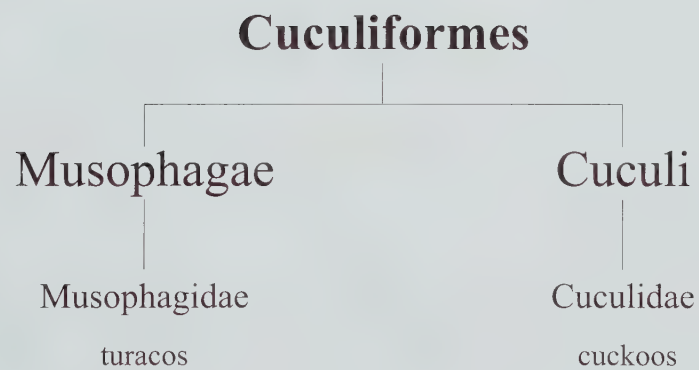

Breeding. Aug-Feb. Nest in natural hollow in old large tree, often a palm trunk, often relatively low down (3-5 m in three cases); birds strongly territorial, and nests may be as much as 2 km apart. In captivity: 2-4 eggs; incubation timed at 28 days; nestling period unknown, but dependence on parents continuing for 3 weeks after fledging.

Movements. Downslope displacements reported to occur in winter, but now known to be a year-round resident. Birds are able to disperse among habitat patches using narrow forest corridors such as strips of second-growth woodland.

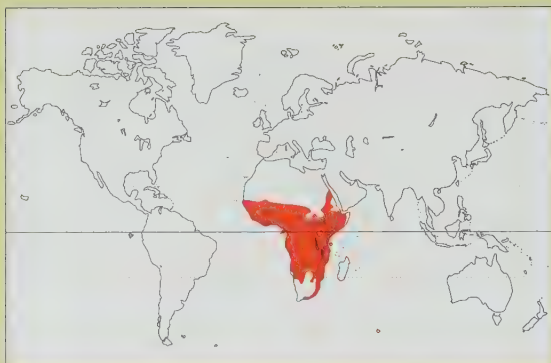

Status and Conservation. ENDANGERED. CITES II. A BirdLife "restricted-range" species. Generally uncommon, apparently being both patchily distributed and at low densities within patches; however, also highly unobtrusive unless distinctive voice known, so status hard to establish. Judged rare in Paraná, but with a maximum of 10,000 individuals in CE Rio Grande do Sul. Suffering from general habitat clearance in many areas, plus hunting for food (notably in winter when in more populated areas), compounded by a moderate amount of trade. In Brazil recorded from Sooretama, Augusto Ruschi and Duas Bocas Biological Reserves (Espírito Santo), Desengano State Park and Serra do Tinguá Biological Reserve (Rio de Janeiro), Serra da Bocaina National Park, Boracéia Biological Station, Intervalles State Park, and Carlos Botelho, Alto Ribeira, Juréia, Jacupiranga and Ilha do Cardoso State Parks (São Paulo), and Aparados da Serra National Park (Rio Grande do Sul); in Argentina, has been recorded in Iguazú National Park and Uruguá-i Natural Reserve. Main strongholds are Intervalles and Botelho, plus the escarpment forests of Rio Grande do Sul, where protected areas, sustainable forest management programmes and education initiatives are urgently needed.

Bibliography. Aleixo & Galetti (1997), Beissinger & Snyder (1992), Belton (1984), Bencke (1996), Bertagnolio (1981), Camargo (1976), Canevari *et al.* (1991), Collar (1996), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Descourtilz (1983), Forrester (1993), Galetti (1996), Guix (1995), Guix *et al.* (1992), Low (1972, 1988b), Murray (1969), Pinto (1938, 1946), Pizo *et al.* (1995), Ridgely (1981), do Rosário (1996), Rumboll (1990), Sick (1968, 1985, 1993), Sick & Teixeira (1979), Stotz *et al.* (1996), Straube & Scherer-Neto (1995), Wege & Long (1995), Whitney (1996).

Order CUCULIFORMES

Class AVES
Order CUCULIFORMES
Suborder MUSOPHAGAE
Family MUSOPHAGIDAE (TURACOS)

- Medium-sized to large, fairly stocky arboreal birds with a rather long tail and short, rounded wings; head often with prominent crest and strikingly coloured; plumage largely glossy.
- 40-75 cm.

- Sub-Saharan Africa.
- Forest, woodland and savanna.
- 6 genera, 23 species, 38 taxa.
- 2 species threatened; none extinct since 1600.

Systematics

Turacos, or louries as they are commonly referred to in southern Africa, are a truly remarkable group of birds now endemic to sub-Saharan Africa. Despite a number of extraordinary features which they exhibit, their evolutionary background remains largely unknown. There are fossil records from the Oligocene of Egypt and Bavaria, and also from the Miocene of France.

While the turacos have normally been placed within the order Cuculiformes, there is increasing evidence that they are not allied with cuckoos but belong in a separate order, the Musophagiformes. Early systematists, including Linnaeus, were clearly influenced by certain superficial resemblances to the cuckoos, and concluded that the two groups were phylogenetically allied. This traditional association of turacos with cuckoos has always been based largely on the fact that the two share the zygodactyl arrangement of the toes, with two toes pointing forward and two pointing back. Other anatomical characters, however, principally feather-tracts, osteology and myology, do not support the relationship.

In his 1886 monograph of the turacos, H. Schalow reviewed the classifications of earlier authors. While noting that several groups had been proposed as their allies, including gamebirds (Galliformes), pigeons (Columbidae), woodpeckers (Picidae), trogons (Trogonidae), parrots (Psittacidae), mousebirds (Coliidae) and rollers (Coraciidae), he felt that the turacos were in fact related to the mousebirds. Later, E. Mayr and D. Amadon reflected the uncertainty about the relationships of cuckoos and turacos by noting the many differences of opinion: first, as to whether or not turacos should be associated with the gamebirds; and, second, whether or not the cuckoos were related to them. They felt it best to place turacos tentatively near the gamebirds; at the same time, however, they considered that it was entirely possible that the Musophagidae were somewhat primitive relatives of the Cuculidae, and so they tentatively followed convention in associating the two families in the same order. R. Verheyen, on the other hand, firmly believed that turacos were indeed related to the galliforms, whereas C. G. Sibley found that the electrophoretic patterns of the egg-white proteins of turacos were totally unlike those of galliforms. In fact, the egg-white evidence allowed Sibley to conclude that turacos and cuckoos were related and should be placed in the same order. However, recent DNA-DNA hybridization evidence presented by Sibley and J. E. Ahlquist suggests that the turacos are not particularly closely related to the cuck-

oos. The turaco lineage may have diverged from the cuckoo lineage in the Cretaceous period, of the order of 100 million years ago.

Within Musophagidae itself, the systematics are complex. Several differing opinions have been offered, and over the last century the family has been subdivided into anything from two to four subfamilies, with four to nine genera and 18-23 species. Three subfamilies are commonly accepted, Corythaerinae, Musophaginae (or Tauracinae) and Criniferinae. While this arrangement has generally been followed, there are exceptions: Verheyen included both Musophaginae and Tauracinae, to make four; and, quite recently, Sibley and Ahlquist admitted only two subfamilies, Musophaginae and Criniferinae. It should be noted

*Subdivision of the
Musophaqidae.*

[Figure: Ian Lewington]

Relationships within the turaco family are not always so clear-cut as they might appear. Some authorities have suggested that the Ruwenzori Turaco and also the Purple-crested Turaco (*Tauraco porphyreolophus*) should be placed in the genus *Musophaga*, although both are perhaps intermediate between that genus and *Tauraco*. Bearing in mind the distinctive bill shape and structure of the Ruwenzori Turaco, as well as its unique territorial call, it seems more apt to place this species in its own monotypic genus, *Ruwenzorornis*.

[*Ruwenzorornis johnstoni johnstoni*, Virunga National Park, north-east Zaire. Photo: Bruce Davidson/Animals Animals]

that Musophaginae is sometimes listed as Tauracinae, but although the latter name has priority, dating from Rafinesque's 1815 name as opposed to Lesson's 1820 one, *Musophaga* is retained as the basis for both the subfamily and family names, on the grounds that it has almost universally been used as the basis of the family name for over 150 years.

Corythaeolinae contains only the monotypic *Corythaeola* of rain forest, clearly an isolated genus which would appear to be without any close relatives.

Musophaginae includes the genera *Tauraco*, *Ruwenzorornis* and *Musophaga*, within which the species composition is controversial. While there are some seventeen forms to consider, those grouped within the *T. persa* superspecies have formed the main subject of discussion. This complex of allopatric forms has in the past been treated as either a single polytypic species, or as three, five or six species. It may be best to treat them as six species with ranges that approach each other very closely, but without any known area of intergradation, suggesting that these forms are reproductively isolated from one another. Indeed, wherever the ranges of these allopatric forms approach each other, the change from one to the other is quite abrupt, and in some cases they are separated by as little as 20-40 km. Recent analyses of vocalizations and chromosome-banding patterns also suggest that this complex of green turacos is one of genetically isolated species and is best treated as comprising six allospecies.

The genus *Musophaga* has traditionally been made up of Ross's Turaco (*Musophaga rossae*) and the Violet Turaco (*Musophaga violacea*). More recently, however, there has been a proposal to enlarge it to embrace four parapatric species in two superspecies. While the Purple-crested Turaco (*Tauraco porphyreolophus*) and the Ruwenzori Turaco (*Ruwenzorornis johnstoni*) may be considered systematically intermediate between *Tauraco* and *Musophaga* by some authors, others prefer to retain the Purple-crested within the genus *Tauraco*, but to place the Ruwenzori Turaco in the monotypic *Ruwenzorornis* on account of its distinctive bill shape and structure and its unique call.

The five dry-country species of the subfamily Criniferinae are traditionally placed in two genera, *Corythaixoides* and *Crinifer*, although it has been suggested that the White-bellied Go-away-bird (*Corythaixoides leucogaster*) is biologically and

geographically intermediate between *Corythaixoides* and *Crinifer*, and should therefore be placed in a monotypic genus, *Criniferoides*. While it shares several of the characters exhibited by the Bare-faced Go-away-bird (*Corythaixoides personatus*) and the Grey Go-away-bird (*Corythaixoides concolor*), it lacks green pigment and certainly appears to be less closely related to them than they are to one another.

Thus, the present treatment recognizes 23 species of turaco in six genera: *Corythaeola* is monotypic; *Tauraco* contains 14 species; *Ruwenzorornis* is again monotypic; *Musophaga* has two species; *Corythaixoides* has three; and *Crinifer* has two. These are grouped in the three subfamilies mentioned above. In attempting to understand relationships between the species, the major difficulties have always been whether the Musophagidae derive originally from stock dwelling in evergreen forest and whether the possession of turacin and/or turacoverdin is a primitive character or not. A point on which there is little disagreement is that the *Musophaga* species must be particularly close to, and derived from, the *Tauraco* species, and that the Grey and Bare-faced Go-away-birds are probably dry-country derivatives of the same forest stock. The Great Blue Turaco (*Corythaeola cristata*) and the two plantain-eaters (*Crinifer*) are, however, difficult to place in the overall evolution of the family. The Great Blue resembles *Tauraco* species in its green pigment, but differs in virtually all other characters. The Eastern Grey Plantain-eater (*Crinifer zonurus*) shares a similar tail pattern with the Great Blue, but little else. Perhaps the most acceptable suggestion is that the Great Blue Turaco, unique in its combination of the pigment uroporphyrin and its tail pattern, is nearest to the ancestral stock. It may also be speculated that the plantain-eaters are independently descended from an earlier line of savanna-adapted turacos, which branched off from the main forest-inhabiting line of turacos before the go-away-birds. The plantain-eaters lost uroporphyrin, and developed, or possibly retained, a type of head feathering now unrepresented elsewhere in the family. Recent DNA-DNA hybridization data indicate that *Crinifer* and *Tauraco* diverged about 50 million years ago, after which the main line of development would have proceeded to the evolution of turacin as well as turacoverdin in the *Tauraco* species, with *Musophaga* diverging later from this branch through the development of a frontal shield and massive deposits of melanin.

Notwithstanding these uncertainties, the turacos remain a family of considerable evolutionary interest, with an unusually high proportion of species belonging to superspecies, and with several species showing quite substantial subspecific morphological differences. Our ignorance of the geological history of Africa is such, however, that it is impossible to produce any detailed hypothesis of the course of turaco evolution on either the ecological or the morphological side. The time involved may well be great, several tens of millions of years, and one can do no more than vaguely envisage the isolation of one population after another. In-depth analytical studies of turaco behaviour, ecology and biochemistry are all needed before we can hope for a better understanding of the relationships of this remarkable family.

Morphological Aspects

Apart from the giant of the family, the Great Blue Turaco, all turacos are medium-sized birds with a rather long tail and short rounded wings. In most species the feathers of the head and breast are largely lacking in barbules, giving them a "hairy" texture. Turacos are unusual among non-passerines in having at least five, instead of four, quills on the alula; in addition, the first and second of these quills are of similar proportions, rather than the second being shorter. Nearly all turaco species have a conspicuous erectile crest, the shape, size and colour of which are highly diversified in the genus *Tauraco*. The bill is strong and decurved. The sexes are generally alike, an exception being found in the White-bellied Go-away-bird, in which the male and female differ only in bill colour.

The flight of turacos is weak and laboured, but, by contrast, the semi-zygodactylous toes enable them to move easily and with

great agility along branches and through vegetation. This unique feature of the toes differs from the truly zygodactyl foot of cuckoos in that the fourth, or outer, toe of turacos can be brought back to form an angle of about 70 degrees with the first toe, or brought forward until it almost touches the third toe. Normally, however, it is held at right angles to the main axis of the foot when the bird is running, standing on a flat surface, or alighting. Such variability is in total contrast to cuckoos, which have the fourth toe permanently reversed.

A unique feature of the family is the presence of two copper pigments, red turacin and green turacoverdin, which are unknown in any other birds, or indeed anywhere else in the Animal Kingdom. Generally, such bright colours in birds are produced by melanins and lipochromes, or by diffraction of light from the feather surface, but not so with turacos. Turacoverdin occurs in several species that do not possess turacin, but turacin does not occur in the absence of turacoverdin. The amount of turacoverdin is also directly correlated with the luxuriance of the habitat, being most developed in species inhabiting lush evergreen forest, and least developed or absent in those living in deciduous woodlands and acacia thornbush. For example, the White-crested Turaco (*Tauraco leucolophus*) is the only *Tauraco* species with no turacoverdin on the head and neck, although that on the breast and mantle is of full intensity. The long-perpetuated fallacy that turacin is washed out of the birds' plumage during rainstorms must once again be refuted: the pigment is soluble only in alkali and in no other solution. Turacin does, however, have a much more limited distribution in the plumage than turacoverdin, occurring only in the wings, crest and nape, and in a small patch on the otherwise all-green breast of the Ruwenzori Turaco and the nominate race of the Purple-crested Turaco. It is a copper complex of an organic substance, uroporphyrin 111, and is present in

Although turacos are noted for their bright, glossy plumage, not all species exhibit such remarkable colours. The Grey Go-away-bird is the plainest member of the family, appearing more or less uniform grey, in keeping with its open-country habitat. In contrast, the members of the genus *Tauraco* have largely green plumage, with conspicuous bright red areas and, generally, variable patterns of black and white on the face. The green coloration is due to the presence over much of the head and body of the copper pigment turacoverdin. The White-crested Turaco is the only member of this genus lacking this pigment on the head and neck.

[Left: *Corythaixoides concolor concolor*, Kruger National Park, South Africa. Photo: Philip van den Berg/ Bruce Coleman.

The head pattern is generally a useful feature in distinguishing similar species of turaco.

The White-cheeked Turaco of montane forests of the Ethiopian Highlands has a large white loreal patch bordered below by a black band, and a prominent but variable white patch on the side of the neck. Its bright red orbital ring is enhanced by large wattles on the upper "eyelid", a diagnostic character visible only at close range. This is one of three turaco species which, for reasons not properly understood, appear to have a reduction in melanin pigment on the back and wing-coverts.

[*Tauraco leucotis*.

ENP Images]

such quantities that the red plumage of a single bird may yield as much as 8 mg of copper and 25 mg of pure uroporphyrin. While turacin occurs in the wings of all *Tauraco* and *Musophaga* species, turacoverdin occurs more widely over the body, over all or part of the head, neck, mantle and breast of the *Tauraco* species. Turacoverdin never appears in the wings except in those of the Great Blue Turaco, and, while largely absent in the go-away-

birds and the plantain-eaters, it does occur on the breast of the Grey and the Bare-faced Go-away-birds. The distribution of these unique copper pigments in relation to habitat is of considerable interest (see Table).

In the *Tauraco* species, melanin is virtually confined to the belly, wings, back and tail. In the *Musophaga* species, the melanin is exceptionally dense and black throughout the entire plumage, except for the red areas on the head and wings. The giant *Corythaeola* has the belly and thighs coloured with a reddish brown melanin unlike that in any other species. A curious case is provided by the White-cheeked Turaco (*Tauraco leucotis*), Ruspoli's Turaco (*Tauraco ruspolii*) and the Purple-crested Turaco, all of which, but especially the last species, have the back and wing-coverts a greyish blue, instead of the rich glossy blue, green or violet seen in all other *Tauraco* species. Since there is no reason to suppose that the Purple-crested is in any way closely related to the other two, the character may be due to convergence, in which case the reduction of melanin in the feathers may be an adaptation to drier conditions. This is, however, pure speculation.

Gloss is also strongly developed in all turacos except the Great Blue, the go-away-birds and the plantain-eaters. The colour of the gloss on the body and tail varies remarkably in the Knysna Turaco (*Tauraco corythaix*), from green in the nominate race to blue in the race *phoebus*. There is also an unbroken cline in the Black-billed Turaco (*Tauraco schuetti*), from the violet-blue of nominate birds, through blue, to green in the race *emini*. In Livingstone's Turaco (*Tauraco livingstonii*) the situation is even more complex, with not only body gloss but also crest length varying considerably: nominate birds have the mantle, scapulars and wings dark green, with a crest length of 65-75 mm; the subspecies *cabanisi*, found in the coastal lowlands of south-east Africa from St Lucia north to Dar-es-Salaam, has the scapulars and wings dull bluish green, tinged with violet, and a crest length as in nominate birds; but inland in eastern Tanzania, the race *reichenowi* has the scapulars and wings more dark bluish and a crest length of less than 65 mm. Such changes in body gloss within a species are not obviously correlated with climatic or other factors, and it is hard to believe that they are adaptive.

On the other hand, if it is assumed that the development of turacoverdin is an ancestral feature of the Musophagidae, and if

we accept that the absence or reduction of green in the plumage is adaptive, then the adaptation has perhaps taken place on three separate occasions: namely, with the plantain-eaters, where reduction of green is complete; with the go-away-birds, in which it is partial; and with the White-crested Turaco, where the reduction is incipient.

Since the green areas of the plumage of *Tauraco* species are far more extensive than the red parts, it is clear that at least 20 mg of copper will be present in the feathers as a whole. It has been shown that a copper content of two parts per million (2 ppm) is common in all fruits, while in young foliage this figure can be much higher. Therefore, if turacos are capable of extracting and utilizing, say, 1 ppm of copper from their food, the requirement for their plumage would be obtained by ingesting some 20 kg of fruit, which should be accomplished every two or three months in those species with both red and green in their plumage. Such power of selection would, however, seem to imply a considerable physiological specialization, and it seems remarkable that, within the same family of birds, some species should show absolutely no signs of possessing it. The apparent absence of turacoverdin in some plumages could, however, be misleading. The pigment may actually be present in the go-away-birds and the plantain-eaters but simply be excreted, with little or no deposition in the feathers.

All turacos have a short, strong bill with a curved culmen. This is ridged in some species, and extended backwards into a frontal plate in others. The extent to which the culmen is rounded, compressed or ridged varies between closely related species, notably the Eastern Grey Plantain-eater and the Western Grey Plantain-eater (*Crinifer piscator*), the Red-crested Turaco (*Tauraco erythrolophus*) and Bannerman's Turaco (*Tauraco bannermani*), and the Ruwenzori and the Purple-crested Turacos. Presumably, the degree of compression or ridging affects the strength of the bill, and such differences may be connected with some particularly hard food in the diet, or with fruit that is difficult to pluck. The nostrils or external nares vary considerably in

shape, from small slits to open circular apertures. They also vary in where they are positioned in the bill and, in some cases, are covered with feathers. The adaptive basis for such differences between otherwise very similar species is unknown. Peculiarities of the bill and nostril have in the past been cited as characters of the monotypic genera *Ruwenzorornis*, *Proturacus* (for Bannerman's) and *Gallirex* (for the Purple-crested), the last two of which are now defunct, but it is only *Ruwenzorornis* that shows other unique qualities.

All species of the genus *Tauraco* have bright red and/or striking black and white patterns on the sides of the head. The red generally consists of bare orbital skin surrounding the eye, but may, as in the Red-crested Turaco, be restricted to little more than the eyelids. In most cases, the facial pattern on the sides of the head takes the form of two white bars and a black patch, these three elements being present in combinations that vary considerably among individuals and races; in some they are greatly modified or even absent. It is assumed that they are important recognition marks, and they may act as isolating mechanisms.

The open-country go-away-birds and plantain-eaters are mainly grey, brown and white, to some extent matching their habitat. Plantain-eaters, however, differ from all other turacos in having the elongated feathers that produce the crest present only on the back of the head and on the nape. Furthermore, the form of the individual feather is itself unique in the entire turaco family. The shorter feathers of the forepart of the head show one specialization that is mirrored to some degree by the feathers of the front of the neck. Even if not actually bristly or spiky, they are all stiff to the touch and have the appearance of being broken off at the tip, since they consist of a few coarse barbs with the barbules reduced; this reduction in barbules is more marked on the head than on the neck.

The flight-feathers of turacos are moulted in an irregular and variable manner. It is reported that a perennial state of moult of the primaries is a character of the Green Turaco (*Tauraco persa*) and the Yellow-billed Turaco (*Tauraco macrorhynchus*). E. and V. Stresemann suggested that it can be best understood by simply considering the primaries as being divided into two groups: an inner one composed of the first five or six feathers, and an outer one comprising the last four or five. As a general rule, but

Most musophagids are medium-sized birds with short, rounded wings and a longish tail. The forest turacos are shy, spending most of their time moving furtively through the canopy, aided by their semi-zygodactylous toes. Unlike the toe arrangement of the cuckoos (*Cuculidae*), which have the outer, fourth, toe permanently reversed, the outer toe of turacos can be moved well back, or be brought forward so that it almost touches the third toe. Nearly all turacos have a conspicuous crest, the size, shape and colour of which are highly diversified in the genus *Tauraco*. The Knysna Turaco is one of a number of species with "helmet-shaped" crests.

[*Tauraco corythaix*, South Africa.
Photo: Roger Tidman/FLPA]

Recent studies indicate that the two turacos of the genus *Musophaga* probably diverged relatively recently from the main *Tauraco* line, developing a large frontal shield and huge deposits of melanin. In the *Tauraco* species, melanin is more or less restricted to the plumage of the back, wings, belly and tail. By contrast, the *Musophaga* species have melanin throughout their entire plumage, apart from areas of red on the head and wings. This dark pigment is extremely dense and produces a glossy bluish black look, as illustrated by this Violet Turaco.

[*Musophaga violacea*, Ivory Coast.
Photo: Roland Seitre/Bios]

Unlike their forest-dwelling relatives, the turacos living in open country are relatively dull in plumage, lacking the bright greens, blues and reds of the former. The species inhabiting savanna and acacia country are predominantly grey, white and brown, colours which to a large extent match their habitat. They all lack turacin, the pigment producing the bright red colours of other turacos, and also lack or have a greatly reduced and restricted amount of turacoverdin, the pigment which is responsible for the green colour shown by most of the Musophagidae. They do, however, retain the typical long tail and crested head of all turacos. This family shows little sexual dimorphism, and the male and female are generally indistinguishable in the field. The one exception is the White-bellied Go-away-bird, but even in this species the male and female differ only in bill colour: the male's bill is blackish, whereas the female has a pea-green bill which becomes yellowish during the breeding season.

[*Corythaixoides leucogaster*, Samburu, Kenya.
Photo: David Hosking/
FLPA]

A remarkable feature of most turacos is the presence of red turacin and green turacoverdin, two copper pigments which in the entire Animal Kingdom are unique to the Musophagidae. The brilliant red in their plumage is, for the most part, confined to the wings, crest and nape, and is most striking on birds in flight, as can be seen on this Schalow's Turaco. Turacin, a copper complex of an organic substance known as uroporphyrin 111, is present in surprisingly large quantities: indeed, the red plumage of a single turaco can yield as much as 8 mg of copper and 25 mg of pure uroporphyrin.

[*Tauraco schalowi*, Masai Mara Game Reserve, Kenya. Photo: Günter Ziesler]

not an invariable one, the moult starts with the loss of one feather from the inner group, usually the first primary, which is followed by primaries 2-5 in descendant order. The descendant sequence, however, may not be closely followed, and any feathers missed out are not shed until all feathers of the outer group have been moulted.

Habitat

Almost without exception, all arboreal habitats in sub-Saharan Africa are occupied by turacos. During the course of their evolution, members of the Musophagidae have colonized all types of forest and woodland, as well as bushed and wooded grassland. In many areas they are also found in well timbered suburban gardens.

Lowland, gallery and montane forests are clearly the most favoured habitats, and the Black-billed, Livingstone's and Great Blue Turacos are the most versatile ecologically. The Black-billed and Livingstone's Turacos have races resident in both lowland and montane forest, while the monotypic Great Blue appears equally at home in low humid equatorial rain forests, along gallery forests that stretch deep into the savanna belt, or at elevations of up to 2000 m in the highland cloud forests around the Albertine Rift.

The montane forests of Africa are important centres of endemism, harbouring a great number of species of various families which are found nowhere else in the world. Five allopatric species of turaco occur in these forests, all of them restricted to quite small and, in some cases, threatened habitats. These are Hartlaub's (*Tauraco hartlaubi*), the White-checked, Ruspoli's, Bannerman's and the Ruwenzori Turacos. Elsewhere, the Green, Yellow-billed, Fischer's (*Tauraco fischeri*) and Knysna Turacos are typically lowland-forest species, while the more open woodlands, along with gallery and riverine forests, are occupied by Schalow's (*Tauraco schalowi*), Purple-crested, Red-crested, White-crested, Violet and Ross's Turacos. While all forests continue to shrink and give way to subsistence agriculture, it is gallery forests that are being destroyed most rapidly, as the low-lying ground they occupy is being increasingly cultivated. In many areas, competition between fruit-eating birds and mam-

mals is becoming increasingly severe at certain times of the year.

The northern savannas of Africa are occupied by the two plantain-eaters, and the eastern and southern acacia habitats by the three go-away-birds. Whereas the Bare-faced and the Grey Go-away-birds are allopatric, the White-bellied Go-away-bird is to some extent sympatric with the Bare-faced in parts of the Ethiopian Rift and central Tanzania. In those areas of sympatry, it is likely that each species frequents and feeds on differing species of acacia.

A relatively small area of northern Angola near Malanje is, for some reason that is not clear, exceptionally rich in turaco species. This would normally not be expected, as the region in question lies between 500 m and 1000 m, and shows no great ecological diversity. It also lacks either rich lowland or typically montane evergreen forest. Rather, the main tree vegetation appears to consist of gallery forest and semi-deciduous woodlands, which themselves may well be relicts of earlier, more extensive areas of closed semi-evergreen forest. In this region, the Green Turaco enters from the north, the Black-billed from the north-east, and Schalow's from the south. While all three are allopatric, their ranges overlap that of the Red-crested Turaco, which is endemic to Angola. Furthermore, the Great Blue Turaco, a typical lowland-forest species, occurs in the same area, as also do Ross's Turaco, which is normally a gallery-forest species, and the Grey Go-away-bird, which is a characteristic bird of acacia country. It seems likely that at least some of the species live here under rather marginal conditions. Indeed, it is difficult to see how competition can be avoided, and it would be most interesting to know just what their ecological relationships are. It may be that the musophagid situation in northern Angola is a transitional one, brought about by recent changes in the vegetation, and liable to change rapidly as further deterioration follows human exploitation and degradation of the environment.

General Habits

The forest turacos belonging to the genera *Corythaeola*, *Tauraco*, *Ruwenzorornis* and *Musophaga* are shy, gregarious birds that only occasionally descend to the ground in order to bathe or drink.

The Musophagidae have, during the course of their evolution, succeeded in occupying virtually all arboreal habitats in sub-Saharan Africa. They have colonized not only all types of forest and woodland, but also savanna with trees or bushes, and in many areas can even be seen in well wooded suburban gardens.

The northern savannas are inhabited by the two plantain-eaters (Crinifer), while the three go-away-birds (Corythaixoides) are typical and noisy birds of the arid eastern and southern acacia belts, represented here by the Bare-faced Go-away-bird.

Most turaco species, however, live in forests, with a clear preference being shown for lowland, gallery and montane forests. The Great Blue Turaco is among the most versatile in terms of its habitat choice, living equally successfully in dense, humid equatorial rain forests, in cloud forests up to 2000 m, and along gallery forests, in some places extending a long distance into the savanna belt. Ross's Turaco generally avoids deep forest. It is one of several species found in tropical Africa's less dense woodlands, as well as in gallery and riverine forests, sometimes wandering out into more open areas with scattered trees.

All turacos are highly territorial, defending an area around the core of their territory from all intruders. Displays are marked by raising and lowering of the long crest accompanied by bowing and tail-flirting; in the *Tauraco* species, the wings are also spread to show off the startling red patches. The nest-site and the young are vigorously defended against any avian or mammalian intruder, no matter how large. In this instance, a Green Turaco is giving a threat display, apparently towards the photographer.

[*Tauraco persa buffoni*, Abuko Nature Reserve, Gambia.
Photo: Philip Perry/FLPA]

Despite being rather poor fliers, they move from tree canopy to tree canopy with remarkable agility. When finally they take flight, they will do so in single file with a short downward glide and a few fast flaps to the next tree, where each will climb and clamber back to the canopy with a series of short hops, leaps and bounds. The plantain-eaters of the savanna are much less agile than their forest relatives, and generally do not run or bound along tree branches. They take flight more readily and, like the three go-away-birds, they will cover longer distances with stronger and more buoyant flight. They also come to ground to drink far more frequently than those turacos living in forest habitats.

Turacos are highly vocal. Frequently, at dawn, a forest turaco will start calling, others nearby will reply, and within a few minutes all birds within earshot will be calling. Imagine that time in the past, when dawn could be heralded across the vast equatorial forests of Africa by groups of forest turacos calling to each other, all the way from the Ituri basin in eastern Zaire to the Atlantic Ocean. Daily activities then generally begin shortly after dawn, and feeding starts early. Later on, as the day warms up, members of a group will preen extensively and bask in the morning sun. A large part of the day is spent feeding, with preening and resting intervals, and a lull in activity occurs during the hottest midday period. After heavy rainstorms, much time is spent "drying out" with wings and tail often fully spread. Towards late evening, turacos begin to move to favourite roosting sites, showing a marked preference for tall leafy trees. Periods of prolonged, noisy calling may be a feature of these journeys to roost sites, as if the birds are encouraging others to join them.

All species of turaco are strongly territorial and remain in family groups for long periods, although most forest turacos live in territorial pairs throughout the year. Territories are generally composed of a core area in which the pair spends most of its time. The core is surrounded by a little-used peripheral area which is defended against intruders. All individuals frequently visit or "raid" other forest patches beyond their territorial borders for food, but they are invariably chased out if met by any resident turaco in those areas. Territory size varies considerably, from approximately 2 km² for the Great Blue and Ross's Turacos in western Kenya to an average of 4 ha per pair for Schalow's on the Nyika Plateau in Malawi, and 15 ha per pair for the Yellow-

billed Turaco in Gabon. Family groups of turacos may not necessarily feed on their closest available food source. At times they will travel quite large distances to reach a particularly favoured fruiting tree, often approaching and leaving it in single file and in total silence.

Species within the genus *Tauraco* are largely allopatric, but, in parts of Gabon where the Yellow-billed and the Green Turacos are sympatric, the former will invariably react aggressively towards the Green wherever the two encounter each other. Such behaviour suggests that the Green Turaco may have entered the dense humid forest in geologically recent times, there meeting and competing with the Yellow-billed. Elsewhere, however, individuals of different genera are often quite tolerant of each other's presence. In some Central African forests it is possible to see Great Blue, Ruwenzori and Black-billed Turacos all feeding in the same fruiting tree, showing aggression only towards other fruit-eating species and monkeys. Nevertheless, when called upon to defend a nest-site, or to protect young against any avian or mammalian intruder, all turacos will do so stoically.

Voice

Just as the raucous call notes of the forest turacos are among the most characteristic sounds of the African rain forests, so the plaintive, nasal calls of the go-away-birds are typical of Africa's acacia savannas.

The loud, resonant "kok-kok-kok" call of the Great Blue Turaco, which sometimes begins and usually ends with a softer, almost trill-like "pruu....pruu", is typically heard at dawn and dusk. This species' voice is always a notable feature of Africa's equatorial forest belt.

The calls of each one of the 14 species of the genus *Tauraco* differ only slightly in tempo and pitch. For the majority of species, the usual call is a loud, harsh barking, often preceded by a higher-pitched hoot. Its function appears to be mainly that of territorial advertisement. Generally, both members of a pair will sing, often in duet, and, in the case of the Green Turaco, one sex has a higher-pitched song than the other; the higher voice is thought perhaps to come from the female, although this is not known for certain. This sexual difference in vocal pitch also exists

The forest turacos are generally shy birds, far more often heard than seen. Their daily activities follow a particular pattern, with relatively little variation. After a bout of loud calling around dawn, followed by early feeding activity, they will then spend some time preening and sunning themselves as the morning temperature rises.

This Hartlaub's Turaco has raised the feathers of its plumage and partly spread its wings and tail in a classic sunning posture.

When turacos become excessively wet after heavy rainstorms, they will dry out their plumage as soon as the sun returns, in this case often resting for lengthy periods with the wings and tail held open to the fullest extent. Much of a turaco's day is, however, taken up with foraging and feeding, until the middle of the day, when, with the tropical sun at its hottest, the birds rest in shaded areas of the forest. Towards late evening, as they start to move to roosting sites in tall, leafy trees, they may once again indulge in much loud calling, before settling down for the night.

[*Tauraco hartlaubi*,
Nairobi suburbs, Kenya.
Photo: Dave Richards]

Almost all bird species need to bathe, at least on occasion, and turacos are no exception. Bathing is a part of the process of plumage maintenance, and is generally followed by extensive preening. The open-country turacos, such as the White-bellied Go-away-bird, will readily descend to the ground to bathe in rain: the wings and tail are widely spread, enabling rain drops to penetrate to each feather of the plumage. The forest turacos, on the other hand, are far less inclined to come to the ground, although they will do so occasionally in order to perform the important functions of drinking or bathing. This captive Red-crested Turaco, a very little known Angolan endemic inhabiting open broadleaf woodland and gallery and riverine forest, appears to have just bathed in a convenient source of water, a sight which would not be so easy to come across in the species' natural home. It is worth reiterating here that, contrary to the often repeated myth that turacin is washed out of the plumage by heavy rain, this pigment is in fact soluble only in alkali and in no other solution.

[Above: *Corythaixoides leucogaster*, Lake Baringo, Kenya. Photo: John Karmali/ FLPA.

Below: *Tauraco erythrolophus*. Photo: Kenneth W. Fink/ Ardea]

in other *Tauraco* species, but it is less pronounced than in the Green Turaco.

The calls of one individual will often stimulate others to respond, and the forest may resound with the birds' raucous calling during vocal periods. This is particularly noticeable in areas occupied by Hartlaub's and Black-billed Turacos. Where two or more species occur together, the calls of one will frequently bring about some quite aggressive responses from another. Such "countersinging" has been observed between Yellow-billed and Green Turacos in Gabon and between Black-billed and Ruwenzori Turacos in Rwanda. Although the normal call of the Ruwenzori Turaco is a series of weak "raw-raw" notes, similar to that of other green turacos, that species also has an extraordinary territorial call, a short explosive "tchick" followed by a rattle or sneeze, that is highly distinct from calls of *Tauraco* or *Musophaga* species.

The two *Musophaga* species, Ross's and the Violet Turacos, utter a long chorus of deep, rolling, gargling "cou-cou-cou-cou-cou-rhou-rhou" notes which tend to run into each other, producing a continuous, pulsating, almost monkey-like sound. This prolonged vibrant noise is even more emphasised when two or more birds call in duet.

The three species of the genus *Corythaixoides* all utter series of loud, plaintive, nasal notes which have resulted in the English name of go-away-bird being used for the group. In southern Africa, the call of the Grey Go-away-bird is described as "g'way, g'way", with the accent on the "way". That of the White-bellied Go-away-bird is a nasal "gaarr, wayrr", repeated several times and frequently given as a series of calls by two birds in asynchronous duet. The Bare-faced Go-away-bird utters a similar

nasal, almost sheep-like "go-ah, go-ah", while several birds together will frequently burst into a series of wild, ringing notes sounding almost like human laughter.

Finally, the two plantain-eaters give a series of high-pitched laughing or cackling "cow-cow-cow" or "how-how-how" notes, followed by a stuttering chatter which gradually fades away. In display flight, a low "ka" or "kalak-kalak-kalak" may accompany each wingbeat, the call varying between the species only in speed and pitch.

Food and Feeding

Turacos are almost exclusively vegetarian, feeding mainly on wild and cultivated fruits and, to a lesser extent, on foliage, flowers and buds. In addition, caterpillars, moths, beetles, snails, slugs and termites are also eaten by several species, particularly during the breeding season. Only the Yellow-billed Turaco is known to follow raiding swarms of ants in mixed-species flocks. Although the English name of plantain-eater is used for two species, and was formerly given to the family as a whole, neither plantains nor cultivated bananas form any part of the diet of any of these birds in the wild.

The Great Blue Turaco indulges in leaf-eating throughout the day, but this habit is particularly pronounced late in the evening. It also feeds regurgitated leaves to its nestlings from the time they reach the age of eight days. Despite their size, Great Blue Turacos are able to reach fruits at the end of very thin branches, thanks to their semi-zygodactylous toes; on occasions, they have been observed briefly hanging upside-down in order

The diet of the Musophagidae is almost totally vegetarian. These birds particularly favour fruits, both wild and cultivated, but some species will also take leaves, buds and flowers. A number of turacos add a few small invertebrates to their diet, but the Purple-crested Turaco appears to take nothing but fruit, especially figs, supplemented with occasional buds. In some parts of its range this species occurs in suburban parks, gardens and exotic plantations, and in southern Africa it regularly visits garden birdtables, where it readily consumes such delicacies as pawpaw (papaya), guava and mulberries, as well as maize-meal. Captive Purple-crested Turacos have been known to consume 134 g of food daily.

The diet of the go-away-birds of acacia savannas is somewhat more varied than that of most forest turacos. In addition to fruit, they also eat the pods, leaves, buds and flowers of acacias and other plants in large quantities, as well as probing the flowers for nectar; the Grey Go-away-bird readily takes emerging termites. The White-bellied Go-away-bird shows a particular liking for the young green pods of *Acacia tortilis*, but it is not known to take termites in the same way as the Grey. Like their forest relatives, however, these open-country turacos also take much fruit. Indeed, the Grey Go-away-bird can be a major pest to man in some areas, raiding orchards and plantations where soft-skinned fruits and vegetables are cultivated. The open, dry habitats in which these turacos live mean that they are subject to similar constraints to those experienced by the savanna-dwelling plantain-eaters (*Crinifer*). All need to drink regularly, and in southern Africa flocks of up to 30 Grey Go-away-birds may be seen visiting isolated water sources. Fluctuating food and water supplies force them to make periodical local wandering movements, and in Zimbabwe, for example, it is not uncommon to see groups of over 50 Grey Go-away-birds moving purposefully in a set direction.

Those musophagid species, like the Western Grey Plantain-eater, that occur in fairly open, dry habitats come to ground to drink far more frequently than do forest turacos, and their similar, almost daily requirement for water results in some local wandering in search of fresh supplies. The two plantain-eaters feed almost solely on fruits. Despite their English name, however, they do not eat either plantains or cultivated bananas in the wild; nor, indeed, does any other member of the Musophagidae, even though the name plantain-eater was formerly applied to the family as a whole.

to reach particular fruits or berries. Although the Great Blue Turaco is larger and has a stronger bill than other members of the family, there is at present no evidence that it eats any particular food to which it might be more adapted than other turacos. In most parts of its range, it eats the same fruits as the smaller species.

Throughout the West and Central African forest zone, fruits of the parasol tree (*Musanga*) and the waterberry tree (*Syzygium*) are particularly favoured, and in areas where *Musanga*, *Polyalthia* and *Cissus* species have regular massive crops their fruits constitute the staple food of most forest turacos. Forest turacos are also considered important agents in the dispersal of seeds of indigenous trees.

In the acacia savannas, the go-away-birds have a more varied diet. This consists not only of fruit, but also of acacia buds, leaves and pods, and *Aloe* and *Erythrina* flowers, as well as emerging termite alates. All go-away-birds drink regularly, and in southern Africa parties of 20-30 Grey Go-away-birds have been recorded at favourite water sources. It is possible that this constant, almost daily need for water may be a limiting factor in their distribution. For example, Grey Go-away-birds are absent from apparently suitable habitat in the dry, waterless central and south-western Kalahari. On at least one occasion, a Grey Go-away-bird has been recorded carrying water in its bill to a nearby newly fledged young bird.

In the northern savannas of Africa, the two plantain-eaters feed almost exclusively on wild and cultivated fruits. In the upper Nile Valley of north-western Uganda, however, the Eastern Grey Plantain-eater reportedly eats the flowers of *Daniellia oliveri* in some quantity.

Breeding

All turacos breed solitarily, in territories which the pair defends strongly. While most species are probably monogamous, some go-away-birds are recorded as having helpers to defend the territory vocally and to assist with the feeding of young in the nest. Such helpers are possibly from a previous brood.

Courtship activity, generally stimulated by the onset of the rainy season, includes much calling and chasing from tree to

tree, mutual feeding, opening and closing of the bill, raising and lowering of the crest, flashing of head markings, bowing, and flirting of the tail, and, in the *Tauraco* species, much spreading of wings to display the crimson patches. The male Western Grey Plantain-eater is reported to rise vertically from the top of a tree and then descend in a tumbling dive to its mate, which remains perched with outstretched wings and tail.

All members of the family build a flat and often flimsy nest of sticks and twigs, very similar to those of doves and pigeons (Columbidae). Nests of the forest turacos are placed among thick foliage 5-20 m above the ground in trees or shrubs, but those of the go-away-birds are generally in acacias, often with little or no attempt at concealment. The clutch size of the savanna species is two or three eggs, whereas all other turacos normally lay just two eggs. The rounded eggs vary in colour from white or greyish white to cream, glossy bluish white or even pale ivory-green. Incubation is carried out by both sexes, and varies from 16-18 days in Hartlaub's to 24-26 days in Ross's and the violet, and 29-31 days in the Great Blue Turaco.

The young hatch at what is, for nidicolous birds, a comparatively advanced stage of development. They have a thick coat of black, grey or brownish down and, in some species, a well developed wing-claw. Their eyes are either open or on the point of opening. The nestlings are fed by regurgitation, and in most species the parents will swallow their chicks' faeces as soon as they are discharged. The young become very active when between two and three weeks old, commonly leaving the nest to clamber about in the surrounding branches long before they can fly. Most make their first flight at four or five weeks, but remain dependent on their parents for some time longer. Young Great Blue Turacos are fed for up to three months after leaving the nest.

While there are few data on breeding success, the African Goshawk (*Accipiter tachiro*) is known to prey heavily on turacos and their nests whenever the opportunity arises. In addition, there are several instances of nests of Great Blue and Ross's Turacos having been raided by blue monkeys (*Cercopithecus mitis*) and by snakes such as the forest cobra (*Naja melanoleuca*). A total of 18 Great Blue Turaco nests, kept under observation during the period from October 1976 to March 1981, gave the following results: from 37 eggs which were laid, 14 young hatched and 11 survived to fledging. Similarly, out of 12 nests of Ross's

All members of the Musophagidae build a flat nest of sticks and twigs, often flimsy, and very like the platform-type constructions of doves and pigeons (Columbidae). The nests of forest turacos, including the Purple-crested Turaco, are sited as much as 20 m above ground in a tree or shrub, usually well concealed among creepers or other thick foliage. The normal clutch is two eggs, which are rather rounded in shape and vary in colour from white to pale greenish; they are incubated by both sexes for 16-31 days, depending on the species. The incubation period of the Purple-crested Turaco is 22-23 days, but that of some other species still remains to be established.

[*Tauraco porphyreolophus porphyreolophus*, South Africa.
Photo: Peter Steyn/Ardea]

Turacos, three were abandoned before laying had started; six clutches totalling 12 eggs hatched, and seven young fledged successfully, while five chicks were killed by predators.

Movements

Most forest species are highly sedentary. Some gallery and riparian species, however, in particular Ross's Turaco and the Purple-crested Turaco, are known to appear periodically at fruiting trees in areas from which they are normally absent. Also in association with the rains, there may be some seasonal dispersal away from the riparian growth into nearby woodlands, again to take advantage of food availability.

Similarly, the plantain-eaters and the go-away-birds inhabiting the savanna and acacia areas undertake some local wandering from time to time in relation to fluctuating food and water supplies. Groups of 50 or more Grey Go-away-birds are not uncommonly encountered in Zimbabwe, moving purposefully in a particular direction.

During periods of drought, or when certain fruits are in short supply, several montane-forest turacos will move altitudinally to feed on alternative food sources.

Relationship with Man

Turacos have long been exploited by man. They have been hunted not only for their brilliant red flight-feathers, which are used as adornments by African royalty and elders, but also for the pot.

Several early explorers mentioned that they made good eating. Notable among these was François Levaillant, who wrote: "I killed...a great number of tauracos, of which we made fricassees, much superior to those made of Guinea-hens or partridges with the same sauce."

In South Africa, legend has it that the Zulu king, Cetshwayo, would permit the feathers to be worn by no-one but himself, although it is believed that they were worn by his 18,000-strong Mbonambi regiment at the battle of Isandhlwana in January 1879, when a British force of 800 was wiped out almost to a man. In East Africa, the feathers from Schalow's and Hartlaub's Turacos are regularly seen in ceremonial headdresses of the Masai tribe, while in West Africa, in Cameroon, a porcupine quill and a red flight-feather from Bannerman's Turaco in a man's black hand-woven hat indicate his position as a *chindoh* or traditional council member.

Throughout southern Africa, the Grey Go-away-bird has long been a bird of ill repute among hunters. The latter will claim that it deliberately warns wild game of their approach, and it does indeed seem to be true that antelopes and other ungulates are alerted by the bird's loud cries. The Grey Go-away-bird is also highly destructive of soft-skinned fruit and vegetables in places where these are grown on a large scale in orchards and horticultural plantations.

In recent years, several species of turaco have adjusted to suburban conditions in many parts of Africa. Today, Hartlaub's Turaco is a common species in the well timbered western and northern suburbs of Nairobi, just as the Purple-crested Turaco has adapted to suburban life in Durban, Lilongwe and Harare, and the Grey Go-away-bird to a similar existence in Johannes-

Young turacos of all species are nidicolous and altricial, being entirely dependent on their parents for warmth and nourishment. Nevertheless, the chicks, on hatching, are relatively well advanced in their development, having a thick coat of dark downy feathering and with their eyes open or on the point of opening. They become very active when two to three weeks old, frequently leaving the nest, but they can not fly for a further two weeks. The newly hatched chicks of Hartlaub's Turaco, a fairly common East African endemic, are reasonably typical of the family. They are covered in black down, and are fed frequently, by both parents, on caterpillars and regurgitated fruit pulp; by 18 days old they can clamber all over the nest tree, spending very little time in the nest itself, and at four weeks of age they are capable of flight. It is interesting to note that this species' incubation period of 16-18 days is the shortest in any turaco.

FLPA]

The nests of the Grey Go-away-bird and its two congeners are similar to those of other turacos, but are generally built in acacias and, unlike those of forest turacos, are easily visible. These birds normally lay three eggs, which hatch asynchronously, but in their brood-rearing behaviour and in the development and behaviour of the nestlings they follow the same pattern as the rest of the family. Turacos are solitary breeders, and are apparently monogamous, but some go-away-birds may have helpers at the nest, possibly birds from a previous brood, which defend the territory vocally and assist with the feeding of nestlings.

burg. Around Kampala and Entebbe in Uganda, the Eastern Grey Plantain-eater is plentiful.

Status and Conservation

As forests and savanna habitats throughout Africa continue to succumb to human pressure, all turacos face varying degrees of threat. Those most threatened are the isolated forest endemics, whose small ranges and often severely fragmented habitats face imminent clearance. As a result, both Bannerman's and Ruspoli's Turacos are currently listed as globally threatened species, with Fischer's Turaco listed as near-threatened.

Bannerman's Turaco is restricted to the Bamenda-Banso Highlands of western Cameroon, and is one of the most threatened bird species in Africa. It is under threat from forest clearance in an area where its habitat had already been reduced by 50% during the twenty-year period from 1965 to 1985, and its continued survival is possible only if the forests on Mount Oku and Mount Ijim are safeguarded. Bannerman's Turaco is a bird of the mid-stratum and canopy levels of the forest, but it is able to survive in damaged secondary forest provided sufficient tall fruiting trees remain. For decades, traditional leaders had been granting farmers the right to clear demarcated areas of forest in order to create new farms. This process was gradual, until world coffee prices began to crash in the early 1980's. Farmers dependent on coffee for income started searching for an alternative cash crop. Noticing that there was a good market for excess beans grown by the women, they seized upon the opportunity. However, they urgently needed more land on which to grow their new crop. They also realized that the small beans grew better at high altitudes and in the fertile soil of newly cleared forest. The demand for forest farms therefore increased dramatically. The continuing forest clearance combined with rampant bush fires meant that, within five years, a vast area of the habitat of Bannerman's Turaco would disappear. As a result, intensive conservation work has been directed towards this area by BirdLife International: farmers who had earlier set their sights on the rich forest soil have been quickly offered an alternative means of income and new farming techniques to ensure the future sustainable use of the forest and its surrounding environ-

ment, together with the saving of this globally threatened species.

Ruspoli's Turaco has a very small and fragmented range in southern Ethiopia, where it lives in juniper forest, mixed broadleaf woodland and acacia woods. Recent surveys suggest that it may

With their attractive plumage, turacos have long been popular among aviculturalists, whose numbers have grown rapidly in recent decades. The long crest of Schalow's Turaco has made this a particularly sought-after species, while in East Africa its feathers are prized by the Masai tribesmen for use in their ceremonial head-dresses. Captive-breeding programmes, involving several turaco species, are now firmly established in many zoos and bird gardens, enabling valuable studies to be made of the birds' behaviour and biology. Appropriate legislation would ensure that only captive-bred turacos were supplied to meet the demands of the many private collections and breeders.

[*Tauraco schalowi*, San Diego Zoo, California, USA. Photo: Kenneth W. Fink]

The continuing clearance of African forests for human exploitation is a serious threat to many bird species, and three turacos are considered threatened or near-threatened. One of these is Fischer's Turaco, which is restricted to a relatively small area of coastal forest from southern Somalia and eastern Kenya to north-eastern Tanzania. The fragmentation of these forest habitats, which continue to diminish in size, poses a serious threat to this species, which is currently considered to number no more than 2000 individuals.

[*Tauraco fischeri*,
Kenya.

Photo: Roland Seitre/Bios]

in fact prefer drier woodlands to forest, and that competition with the White-cheeked Turaco may not after all be a factor in its apparent scarcity. Unfortunately, human pressure and demands for wood-cutting and grazing land are increasing throughout southern Ethiopia. As with Bannerman's Turaco, there is now an urgent need for conservation bodies to implement recommendations for the permanent safeguarding and protection of the preferred habitat of Ruspoli's Turaco.

Since coastal forests in eastern and southern Africa are small, and are generally surrounded by dense human populations, deforestation is particularly severe and is a continuing process. In these fragmented forests, Fischer's Turaco and, to a lesser extent, the Knysna Turaco are being seriously affected. Fischer's has a particularly restricted and diminishing range in southern Somalia, coastal Kenya and north-eastern Tanzania, with a total population of fewer than 2000 birds.

Elsewhere in East Africa, the Purple-crested Turaco is considered a regionally near-threatened species because of continuing habitat loss and the permanent degradation of its gallery and riverine habitats. It is now feared that its overall regional population in East Africa is in serious decline.

The Red-crested Turaco is endemic to war-torn Angola. With clearance of the submontane forests on the Angola Escarpment and continuing degradation of its broadleaf woodlands, it is thought that this species could be facing important habitat loss.

In total contrast, the giant of the family, the Great Blue Turaco, a unique isolated genus without any near relatives, remains the most widespread species in the Musophagidae: it occurs in all 22 countries embracing the equatorial forest belt. Despite its huge size, there is nothing to suggest that it has adapted to any special aspect of its forest environment or to a particular food source, as it shares both with several smaller species. Although hunted over much of West Africa, it remains fairly common throughout its extensive range, with deforestation the main threat.

Although not immediately threatened, several turaco species are listed as birds of restricted range: defined as species with a total distribution that covers an area of less than 50,000 km². For example, Hartlaub's Turaco, the Ruwenzori Turaco and the Bare-faced Go-away-bird qualify for this category, and are birds whose conservation should be dealt with at the East African regional level. Together with its various regional partners in Africa,

BirdLife International is the leader in identifying species which face varying degrees of threat, and is active in its efforts to help conserve and safeguard endangered species and their habitats. The recent drawing-up of endemic bird areas (EBA's) is a major step forward in identifying priority areas for global and regional conservation.

Sadly, the trapping and export of turacos has had its effect on some species. In Tanzania, the export of Hartlaub's, Fischer's, Livingstone's and the Purple-crested Turacos reached quite alarming proportions prior to 1994; fortunately, all trade in birds is now regulated under a Government quota system whereby licensed exporters are required to obtain minimum foreign-exchange values for the birds they export. Similarly, the hundreds of turacos that are exported annually from Guinea, Sierra Leone, Liberia and Ghana are giving much cause for concern; if sustained on the current scale, this trade will clearly deplete populations of the Violet, Green and Great Blue Turacos in those parts of West Africa. Meanwhile, the Wildlife Trade Monitoring Unit of IUCN maintains a watchful eye on all aspects of trade in wildlife, including that involving turacos. With stricter controls now in force in most European Union countries and other parts of the world, it is hoped that the importation of wild turacos from Africa will be reduced.

Many zoos and bird gardens around the world have now established highly successful captive-breeding programmes involving several species of turaco, and valuable data are becoming available from studies of these captive-bred birds. It is very much to be hoped that, in the very near future, legislation will ensure that only such birds bred in captivity will be available to the hundreds of private aviaries and turaco-breeders that have proliferated in recent years.

Subfamily CORYTHAEOLINAE

Genus *CORYTHAEOLA* Heine, 1860

1. Great Blue Turaco

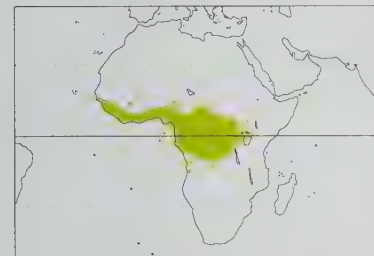

Corythaeola cristata

French: Touraco géant **German:** Riesenturako **Spanish:** Turaco Gigante
Other common names: Great Turaco, (Great) Blue Plantain-eater

Taxonomy. *Musophaga cristata* Vieillot, 1816, Sierra Leone.

E African birds formerly separated in race *yalensis*. Monotypic.

Distribution. Equatorial Africa from Guinea Bissau, Guinea, Liberia and Ivory Coast E to Nigeria, Central African Republic, Cameroon, Bioko (Fernando Po), Gabon, N Angola, Congo, Zaire, S Sudan, Uganda, Rwanda, Burundi, NW Tanzania and W Kenya.

Descriptive notes. 70-75 cm; male 857-949 g, female 822-1231 g. Readily identified by large size and predominantly grey-blue or greenish blue and yellow plumage; crest blue-black; long, wide tail with broad black subterminal band, narrow blue tip in most birds; belly, tibial feathers and undertail-coverts chestnut; no red in wings; large bill bright yellow, tipped red; eye dark red; orbital skin blackish; legs and feet blackish. Sexes alike. Immature duller, with smaller crest.

Habitat. Lowland, intermediate and montane rain forest, as well as heavy gallery forest; where not molested or persecuted, survives well

in small relict forest patches. Sea-level to 2700 m.

Food and Feeding. Largely frugivorous, but buds, shoots, leaves and flowers also taken. In W Africa favours fruits of *Musanga*, also *Cissus*, *Polyalthia*, *Heisteria*, *Ficus*, *Dacryodes*, *Pachypodanthium*, *Uapaca*, *Strombosia*, *Trichilia*, *Drypetes*, *Viscum*, *Beilschmiedia*, *Coelocaryon*, *Croton* and *Pycnanthus*; some insects also taken. In W Kenya eats fruits of *Bridelia micrantha*, *Cordia abyssinica* and, when available, large quantities of loquats (*Eriobotrya japonica*) and guavas (*Psidium guajava*); also takes fruits of *Olea welwitschii* and *Ficus thonningii*, and flowers of *Markhamia platycalyx*. Leaves are readily eaten throughout the day, but leaf-eating particularly pronounced in the evening; regurgitated leaves fed to nestlings.

Breeding. May in Nigeria; Feb, May-Jul and Sept-Dec in Cameroon; Mar, Aug-Sept and Dec in Gabon; Mar-Apr and Sept in Zaire (Itombwe); Jan-Jul, Sept and Nov-Dec in Uganda and W Kenya. Nest usually a platform of dry sticks with a shallow rim, built by both sexes at 8-25 m in tall leafy tree, often over water. Generally 2 eggs, pale bluish green and almost spherical; incubation 29-31 days, by both sexes. Once young hatched, parents most attentive and one always in attendance at nest day and night until nestlings 27-29 days old; young fed by both parents, often assisted by a helper; in 4th week nestlings climb in and out of nest, at 27-33 days make short flights in the tree, finally leaving nest at 31-38 days. Parents remain close by until young 45 days old and able to fly more strongly; continue to feed young for up to 3 months.

Movements. Groups of 6-7 birds, occasionally more, maintain territories throughout year; solitary individuals rare. Frequently moves some distance to favoured fruiting trees, returning daily for several days in succession, but generally approaching the tree silently, and leaving one at a time. Several groups often congregate at large fruiting trees near borders of territories.

Status and Conservation. Not globally threatened. Most widespread of all turacos, and seems not uncommon in most of range. Locally common in W Uganda. Although adaptable to some extent, and able to accept smaller areas of forest if not persecuted, numbers in Nigeria greatly depleted by unremitting deforestation. Hunted widely over much of W Africa, where considered a delicacy by local inhabitants; despite such pressure, still widespread and common in Sierra Leone. Trapping for export could result in depletion of some populations. Nests may occasionally be raided by blue monkeys (*Cercopithecus mitis*) and by snakes, but this appears not to be a great problem. CITES III in Ghana.

Bannerman (1933, 1953), Bates (1927), Britton (1980a), Brosset & Erard (1986), Brown & Britton (1980), Candy (1984), Cave & Macdonald (1955), Chapin (1939), Cheke & Walsh (1996), Colston & Curry-Lindahl (1986), Dowsett (1989, 1990), Dowsett & Dowsett-Lemaire (1991), Dowsett & Forbes-Watson (1993), Lutson & Branscombe (1990), Elgood *et al.* (1994), Fry *et al.* (1988), Grimes (1987), Hauser & Wrangham (1990), Jackson & Sclater (1938), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1981), Mackworth-Præd & Grant (1957, 1962, 1970), Nikolaus (1987), Pérez del Val (1996), Pinto (1983), Reinhard & Blaskiewicz (1981), Rutgers & Norris (1972), Short *et al.* (1990), Snow (1978), Sun & Moermond (1997), Thiollay (1985), Zimmerman (1972), Zimmerman *et al.* (1996).

Subfamily MUSOPHAGINAE

Genus *TAURACO* Kluk, 1779

2. Green Turaco

Tauraco persa

French: Touraco vert **German:** Guineaturako **Spanish:** Turaco de Guinea
Other common names: Green Lourie, Guinea/Green-crested Turaco

Taxonomy. *Cuculus Persa* Linnaeus, 1758, Ghana.

Forms a superspecies with *T. livingstonii*, *T. schalowi*, *T. corythaix*, *T. schuetti* and *T. fischeri*, a complex of allopatric forms formerly treated variably either as a single polytypic species or as three, five or six species. Three subspecies recognized.

Subspecies and Distribution.

T. p. buffoni (Vieillot, 1819) - Senegambia to Liberia.

T. p. persa (Linnaeus, 1758) - Ivory Coast and Ghana E to Mt Cameroon and Bamenda Highlands.

T. p. zenkeri (Reichenow, 1896) - S Cameroon, Gabon, N Angola, Congo and NW Zaire.

Descriptive notes. 40-43 cm; 225-290 g. Adult has head and erectile crest, neck, breast and mantle grass-green; lower back, rump and tail dull blackish with metallic violet and purplish gloss; belly and undertail-coverts dull black; remiges bright crimson, bordered and tipped with black; white loreal patch adjoining narrow black stripe under eye, variably bordered below by narrow white one; eye brown with scarlet eyelid; bill brownish red with black tip; legs and feet blackish. Immature similar, but with more extensive black tipping to primaries. Races differ mainly in head markings: nominate *persa* has white line under eye broadest

and longest (extending behind eye), and often slightly reddish tinge to tips of crest feathers; *zenkeri* has narrow and short white line below eye, faint purplish tinge to tips of crest; in *buffoni* white stripe below eye generally absent or barely visible, crest often without red or purple tips.

Habitat. Widespread in W African lowland and gallery forests; generally prefers areas of older secondary growth, particularly at edges of cultivation and along rivers and other watercourses. Typically from sea-level to 1100 m, but to 1385 m in Bamenda Highlands, Cameroon.

Food and Feeding. Wide variety of wild and cultivated fruits, also flowers and buds. In Gabon eats fruits of *Musanga*, *Ficus lingua*, *Phoenix reclinata*, *Heisteria parvifolia*, *Coelocaryon*, *Polyalthia*, *Rauwolfia*, *Macaranga*, *Cissus* and *Solanum*.

Breeding. Breeds May-Jun and Aug in Cameroon, Dec-Feb and Jun-Sept in Gabon; records in Jun and Oct in Sierra Leone. Nest a roughly built platform of sticks and twigs, interlaced with fine twigs, bulkier than that of a dove (Columbidae), and 1.5-5.3 m above ground in thickest part of an isolated bush or tree. Generally 2 eggs, creamy-white without gloss and almost spherical in shape; incubation 21-23 days, by both sexes; young remain in nest 26-28 days, making their first flight at 38 days; in Gabon 2 nestlings seldom raised, 1 generally disappearing shortly after hatching. Fledglings dependent upon parents for up to 14-15 weeks.

Movements. Largely sedentary throughout its W African range; in Gabon strongly territorial, with pairs maintaining a territory all year. Individuals occasionally wander seasonally to riverine and gallery forests in search of food, but no regular movements.

Status and Conservation. Not globally threatened. CITES II. Fairly common and widespread over much of its range, but no real information on numbers. No data on densities, but territories in Gabon normally c. 15 ha. In Sierra Leone, particularly abundant in gallery forests.

Bibliography. Bannerman (1933, 1953), Bates (1930), Brosset & Erard (1986), Chapin (1939), Cheke & Walsh (1996), Colston & Curry-Lindahl (1986), Decoux & Erard (1992), Dowsett (1989), Dowsett & Dowsett-Lemaire (1991, 1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1988), Elgood *et al.* (1994), Fry *et al.* (1988), Good (1952), Gore (1990), Grimes (1987), Horne (1991), Jensen & Kirkeby (1980), Lamarche (1980), Lippens & Wille (1976), Louette (1981), Mackworth-Præd & Grant (1962, 1970), Morel & Morel (1990), Pinto (1983), Roles (1971), Rutgers & Norris (1972), Snow (1978), Thiollay (1985), Wachter (1993), White (1965).

3. Livingstone's Turaco

Tauraco livingstonii

French: Touraco de Livingstone **German:** Livingstoneturako **Spanish:** Turaco de Livingstone
Other common names: Livingstone's Lourie

Taxonomy. *Turacus livingstonii* G. R. Gray, 1864, southern Malawi.

A member of the *T. persa* superspecies. Formerly treated as conspecific with *T. schalowi* and *T. corythaix*, but vocal differences and cytogenetic researches point to specific recognition. Three subspecies recognized.

Subspecies and Distribution.

T. l. reichenowi (Fischer, 1880) - Nguru and Uluguru Mts SE to Dabaga and Njombe Highlands, Tanzania.

T. l. cabanisi (Reichenow, 1883) - coastal lowlands of Tanzania S of R Mligasi through Mozambique to NE Zululand.

T. l. livingstonii (G. R. Gray, 1864) - highlands E of the Rift in Malawi and adjacent N Mozambique, S to E Zimbabwe (Inyanga to Mt Selinda).

Small disjunct population in E Burundi and W Tanzania not racially assigned.

Descriptive notes. 45-46 cm; male 280-380 g, female 262-350 g. Adult has long green crest, tipped white; upperparts vary racially, from green to blue; belly and undertail-coverts dull black; remiges bright crimson with black tips; white stripe from gape to front of eye separated from one running under eye to ear-coverts by small black loreal patch; eye brown; orbital skin red; bill pinkish red. Immature duller than adult, with shorter crest, darker bill. Races vary remarkably in colour: nominate has mantle, scapulars, wings and tail dark green, feathers with broad emerald edges imparting scaled effect, crest 65-75 mm; *cabanisi* has mantle green, but scapulars, wings and tail dull bluish with violet tinge; *reichenowi* similar to previous, but scapulars, wings, rump and tail much deeper blue, crest less than 65 mm.

Habitat. Coastal and montane evergreen forest, from sea-level to 2500 m.

On following pages: 4. Schalow's Turaco (*Tauraco schalowi*); 5. Knysna Turaco (*Tauraco corythaix*); 6. Black-billed Turaco (*Tauraco schuetti*); 7. Fischer's Turaco (*Tauraco fischeri*); 8. Yellow-billed Turaco (*Tauraco macrorhynchus*); 9. White-crested Turaco (*Tauraco leucolophus*); 10. Bannerman's Turaco (*Tauraco bannermani*); 11. Red-crested Turaco (*Tauraco erythrolophus*).

Food and Feeding. Primarily a fruit-eater. In Malawi diet overlaps greatly with that of *T. schalowi*, 80% of species consumed being common to both.

Breeding. Breeds Oct-Dec in Malawi, Dec-Jan and Jun in Mozambique, Sept-Feb in Zimbabwe. Nest a well-woven platform of sticks and twigs some 3-10 m above ground in thickest part of a bush or tree. Lays 2 white and smooth-shelled eggs; incubation 22-23 days, by both sexes.

Movements. Largely sedentary throughout its range.

Status and Conservation. Not globally threatened. CITES II. Fairly common over much of its range, but continuing forest clearance will ultimately have adverse effect on all races. Some Tanzanian populations subject to indiscriminate trapping and subsequent export, although this potential threat now on a smaller scale than in years preceding 1994.

Bibliography. Benson & Benson (1977), Britton (1980a), Clancey (1952, 1989a, 1992, 1996), Dillingham & Moreau (1961), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire (1989), Dowsett-Lemaire & Dowsett (1988), Evans & Anderson (1992), Friedmann & Loveridge (1937), Fry *et al.* (1988), Ginn *et al.* (1989), Mackworth-Praed & Grant (1957, 1962), Maclean (1993), Newman (1996), Russell (1981b), Rutgers & Norris (1972), Short *et al.* (1990), Sinclair (1987), Snow (1978).

4. Schalow's Turaco

Tauraco schalowi

French: Touraco de Schalow

German: Schalowturako

Spanish: Turaco de Schalow

Taxonomy. *Corythaix schalowi* Reichenow, 1891, Angola.

A member of the *T. persa* superspecies. Formerly considered conspecific with *T. livingstonii* and *T. corythaix*, but vocal differences and analysis of chromosome banding suggest specific recognition more appropriate. Several races described for E populations, including *marungensis*, *loitanus* and *chalcophilus*, but all of doubtful validity. Monotypic.

Distribution. W, C & E Angola (N to Malanje and Calandula), S Zaire and Zambia to Zimbabwe (W of Victoria Falls), Malawi (W of the Rift), and W Tanzania from Ufipa to Gombe Stream National Park; smaller disjunct population in SW Kenya and N Tanzania from Mara Game Reserve and Loita Hills S to N & W Serengeti National Park, Crater and Mbulu Highlands and Mt Hanang, and W to Mwanza District.

Descriptive notes. 41-44 cm; male 236-261 g, female 208-267 g. Similar to *T. livingstonii*, but with longer and more attenuated crest (80-112 mm), more greenish mantle and wings, paler green underparts, and deep bluish black to violet tail; white line under eye present on most individuals, but may be greatly reduced or even absent on N Tanzanian birds.

Habitat. Gallery or evergreen forest, thickets and riparian woodland, from 600 m to 2500 m.

Food and Feeding. Primarily a fruit-eater. On Nyika Plateau in Malawi, favours *Cryptocarya liebertiana*, *Drypetes gerrardii*, *Cassine*

ethiopica, *Podocarpus latifolius*, *Olea capensis*, and *Syzygium* and *Rapanea* species.

Breeding. Breeds Dec-Mar in SW Tanzania, Jul-Oct in Kenya, Oct-Dec in Malawi, and Oct-Jan in Zambia. Nest a flimsy structure of sticks some 3-10 m above ground in thickest part of tree or bush. Lays 2 oval eggs, white without gloss; incubation 20-22 days, by both sexes.

Movements. Largely sedentary throughout its range.

Status and Conservation. Not globally threatened. CITES II. Common on Nyika Plateau, Malawi, where 43 small areas of forest totalling 157 ha contained 39 pairs, giving average territory 4 ha/pair.

Bibliography. Benson & Benson (1977), Benson *et al.* (1971), Britton (1980a), Chapin (1939), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire (1983), Dowsett-Lemaire & Dowsett (1988), Fry *et al.* (1988), Ginn *et al.* (1989), Jackson & Selater (1938), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Praed & Grant (1957, 1962, 1970), Maclean (1993), Newman (1996), Newman *et al.* (1992), Pinto (1983), Rutgers & Norris (1972), Short *et al.* (1990), Sinclair (1987), Snow (1978), Zimmerman *et al.* (1996).

5. Knysna Turaco

Tauraco corythaix

French: Touraco louri

German: Helmturako

Spanish: Turaco de Knysna

Other common names: Knysna Lourie

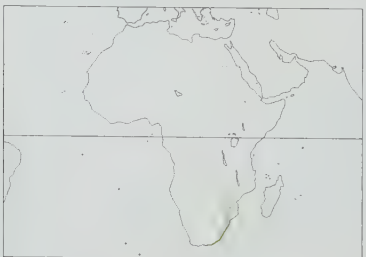

Taxonomy. *Spelectos corythaix* Wagler, 1827, Cape of Good Hope.

A member of the *T. persa* superspecies. Formerly considered conspecific with *T. livingstonii* and *T. schalowi*, but differences in vocalizations and chromosome-banding analysis suggest otherwise. Two subspecies recognized.

Subspecies and Distribution.

T. c. phoebus Neumann, 1907 - E & N Transvaal and NW Swaziland.

T. c. corythaix (Wagler, 1827) - Natal, W Zululand and S Swaziland to S & E Cape Province.

Descriptive notes. 45-47 cm; male 280-380 g, female 262-350 g. Adult has rounded, erectile, "helmet-like" crest green, tipped white; head, neck, breast and mantle bright green; tail, rump, back, scapulars and wing-coverts dark metallic green with emerald and violet-blue glosses; belly and undertail-coverts dull blackish, washed with green; remiges bright crimson with blackish tips; white stripe from gape to top of eye is separated from one running under eye to ear-coverts by small black loreal patch; eye brown, orbital ring red; bill orange-red; legs blackish. Immature duller than adult, less red in wings, crest shorter and bill olive-

brown. Race *phoebus* similar, though with more intense steel-blue gloss on back and wings.

Habitat. Coastal and inland evergreen forest, from sea-level to 1800 m.

Food and Feeding. Although primarily a fruit-eater, particularly favouring *Rothmannia capensis*, *Rapanea melanophloeos*, *Apodytes dimidiata* and *Olea capensis*, will also eat with impunity the fruits of bushman's poison (*Acokanthera spectabilis*), which are highly toxic to mammals. Also

takes seeds, leaf buds of *Bauhinia* and *Ficus*, and flowering heads of the cabbage-tree (*Cussonia*). In captivity, total fruit intake was 124 g/day, and parents actively searched for insects and earthworms during chick-feeding stage, but not at other times.

Breeding. Breeds Nov-Jan and Jun-Jul in S & E Cape Province, Aug-Nov in Natal. Nest a shallow platform of sticks, much like that of a large dove (Columbidae), c. 2-9 m above ground in leafy tree or among dense creepers. Lays 2, occasionally 3, smooth white eggs; incubation 23-26 days, by both sexes; young fed by regurgitation, remain in nest for 22-26 days, making first flight at 28-35 days, but dependent upon parents for several weeks more.

Movements. Mainly sedentary throughout its range.

Status and Conservation. Not globally threatened. CITES II. A fairly common resident over much of its range, but the ever-shrinking extent of coastal forests in Cape Province and adjacent areas will ultimately affect the population of nominate *T. c. corythaix*.

Bibliography. Clancey (1964b, 1975, 1989a), Courtenay-Latimer (1942), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire & Dowsett (1988), Fry *et al.* (1988), Ginn *et al.* (1989), Huisamen (1995), Jarvis & Currie (1979), Jubb (1965), Mackworth-Praed & Grant (1962), Maclean (1993), Newman (1996), Rowan (1983), Russell (1981b), Rutgers & Norris (1972), Sinclair (1987), Snow (1978).

6. Black-billed Turaco

Tauraco schuetti

French: Touraco à bec noir

German: Schwarzschnabelturako

Spanish: Turaco Piquinegro

Taxonomy. *Corythaix Schüttii* Cabanis, 1879, Tala Magongo, Angola.

Member of the *T. persa* superspecies. Two additional localized forms (*sharpei* and *finschi*) described, but doubtfully valid, owing to much intergradation with *emini* and nominate *schuetti*. Two subspecies recognized.

Subspecies and Distribution.

T. s. emini (Reichenow, 1893) - S Sudan, E Zaire, Uganda and W Kenya to NW Tanzania, Burundi and Rwanda.

T. s. schuetti (Cabanis, 1879) - Zaire E to Ituri basin, S to Angolan border.

Descriptive notes. c. 40 cm; male 215-267 g, female 199-272 g. Adult very similar to *T. persa*, but with a small and almost all-black bill, and a more evenly rounded crest tipped with white. Mantle, rump, uppertail-coverts and folded wings violet-blue; lower breast to undertail-coverts dusky; white line in front of and under the eye separated by a thin black loreal patch; eyes hazel-brown; eyelids and orbital skin above and behind eye red; base of lower mandible dark red; legs and feet blackish. Immature similar to adult, but bill entirely black. Race *emini* has mantle, rump, uppertail-coverts and folded wings dark green; also

many blue intermediates between this and violet-blue nominate birds.

Habitat. Canopy of lowland, intermediate and montane evergreen forest, from 500 m to 2800 m.

Food and Feeding. Strictly frugivorous: particularly favours fruits of *Alangium*, *Ekebergia*, *Ficus*, *Ilex*, *Maesa*, *Mosanga*, *Olea*, *Olinia*, *Podocarpus*, *Polyscias*, *Prunus*, *Sapium* and *Syzygium*.

Breeding. Breeds Mar, May, Aug-Sept and Dec in Zaire; Feb and May in Uganda. Nest a frail platform of twigs some 3-5 m above ground in thick tangled secondary growth. Lays 2 white eggs; incubation by both sexes.

Movements. Largely sedentary throughout range.

Status and Conservation. Not globally threatened. CITES II. Plentiful throughout much of its range, particularly in Zaire, where its resonant "khaw, khaw, khaw..." call is one of the most characteristic year-round sounds of the forest.

Bibliography. Bannerman (1933), Britton (1980a), Cave & Macdonald (1955), Chapin (1939), Dowsett (1989, 1990), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Jackson & Selater (1938), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Praed & Grant (1957, 1970), Nikolaus (1987), Pinto (1983), Rutgers & Norris (1972), Short *et al.* (1990), Snow (1978), Sun & Moermond (1997), Zimmerman (1972), Zimmerman *et al.* (1996).

7. Fischer's Turaco

Tauraco fischeri

French: Touraco de Fischer

German: Fischerturako

Spanish: Turaco de Fischer

Taxonomy. *Corythaix Fischeri* Reichenow, 1878, Witu, Kenya.

A member of the *T. persa* superspecies. Two subspecies recognized.

Subspecies and Distribution.

T. f. fischeri (Reichenow, 1878) - S Somalia, coastal Kenya (inland along R Tana to Bura), and NE Tanzania from E Usambaras S to R Wami.

T. f. zanzibariensis Pakenham, 1938 - Zanzibar.

Descriptive notes. c. 40 cm; male 230-269 g, female 227-283 g. Unmistakable with white-tipped crimson crest, blackish at tallest point; nape also crimson; upperparts, including wings, rump and tail, greenish blue; lower belly blackish; primaries and inner secondaries crimson; white line from front of eye to bill separated from one under eye and extending to ear-coverts by small black loreal patch; eye brown, bare orbital skin red, surrounded by thin black ring; bill bright red; legs and feet blackish. Immature similar. Race *zanzibariensis* differs in having upperparts, wings, rump and tail violet-blue, not greenish blue.

Habitat. Forest and wooded thickets, favouring canopy and sub-canopy of mature fruiting trees. Sea-level to 1250 m, rarely 1450 m.

Food and Feeding. Primarily a fruit-eater: particular preference for the yellow berries of *Pachystela brevipes*. Also flower buds and young, pale green leaf shoots of *Azela cuanensis*. Occasionally eats insects which it encounters opportunistically while foraging.

Breeding. Breeds Jun in Kenya. Nest a frail platform of twigs placed 3-10 m above ground in thick tree foliage. Lays 2 almost spherical off-white eggs; incubation 22-23 days, by both sexes. Newly hatched young are covered in dark brown down, and as early as 10 days are hopping and crawling among nearby branches.

Movements. Largely sedentary in all areas.
Status and Conservation. Not globally threatened. CITES II. Currently considered near-threatened. Both races seriously affected by trapping and continuing clearance of coastal forests. The world population probably numbers no more than 2000 individuals, and the conservation status of this turaco may require re-evaluation. The population is small and endangered in S Somalia, where the species is restricted to the lower Juba Valley, while in Kenya and NE Tanzania it is common only in the Shimba Hills National Park and the E Usambara lowland forests. Race *zanzibarius* restricted to Zanzibar, where total population probably under 50 pairs.
Bibliography. Ash & Miskell (1983), Britton (1980a), Britton & Britton (1976), Britton & Zimmerman (1979), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Jackson & Selater (1938), King (1978/79), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1957), Milne (1991), Pakenham (1938, 1979), Paterson (1993), Short *et al.* (1990), Snow (1978), Zimmerman *et al.* (1996).

8. Yellow-billed Turaco

Tauraco macrorhynchus

French: Touraco à gros bec **German:** Blaurückenturako **Spanish:** Turaco Piquigualdo
Other common names: Black-tipped Crested/Verreaux's Turaco

Taxonomy. *Corythaix macrorhynchus* Fraser, 1839, Sierra Leone. Two subspecies recognized.
Subspecies and Distribution.
T. m. macrorhynchus (Fraser, 1839) - Sierra Leone E to Ghana.
T. m. verreauxii (Schlegel, 1854) - Nigeria, Cameroon and Bioko (Fernando Póo) S to Gabon, SW Congo, W Zaire and N Angola (Cabinda).

Descriptive notes. 40-43 cm; male 261-272 g, female 216-234 g. Head, neck and breast green; rounded helmet-like crest green, tipped black and white; wing-coverts, inner secondaries, scapulars, mantle, rump and tail glossy violet-blue; primaries and outer secondaries crimson; belly blackish, washed with green, undertail-coverts black; small velvety black patch below lores extends back in very thin black line, while under it a broader white one extends from gape to ear-coverts; eye dark brown, with bright red wattled orbital ring surrounded by thin black line; large bill bright yellow usually with dark red base; legs and feet black. Immature

duller. Race *verreauxii* has crest tipped crimson and black, not black and white, and violet-blue of upperparts heavily washed with green.

Habitat. Lowland and montane gallery forest; largely restricted to primary forest, only rarely wandering into secondary growth. Sea-level to 1600 m.

Food and Feeding. Primarily a fruit-eater, particularly favouring *Musanga*, *Coelocaryon*, *Polyalthia*, *Cissus*, *Heisteria*, *Maesopsis*, *Pachypodanthium*, *Trichilia*, *Uapaca*, *Macaranga*, *Trichoscapha*, *Ficus*, *Hugonia* and *Dacryodes*. Also eats tree seeds and shoots, as well as snails and insects flushed by swarms of army ants.

Breeding. Dec and Feb in Sierra Leone; Jun-Aug and Dec-Jan in Cameroon; and May-Jun, Aug and Dec-Jan in Gabon. Nest a flimsy platform of dry twigs, well hidden in tree foliage, 7-10 m above ground; reports of ground nesting on Bioko require confirmation. Lays 2 oval, creamy-white eggs; incubation by both sexes.

Movements. Sedentary in all areas.
Status and Conservation. Not globally threatened. CITES II. Reported to be not uncommon, or even common, in primary forest at Mt Nimba in Liberia, around Makokou in Gabon, and in suitable habitat in Sierra Leone, but few data on actual numbers. Elsewhere appears to be uncommon, although it may be overlooked or perhaps confused with similar species. The fact that it seems to be restricted largely to primary forest could make it especially vulnerable to further deforestation and localized tree-felling.

Bibliography. Bannerman (1933, 1953), Brosset & Énard (1986), Chapin (1939), Colston & Curry-Lindahl (1986), Decoux & Énard (1992), Dowsett (1989), Dowsett & Dowsett-Lemaire (1991), Dowsett & Forbes-Watson (1993), Dutson & Branscombe (1990), Elgood *et al.* (1994), Fry *et al.* (1988), Green (1990), Grimes (1987), Halleux (1994), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1970), Pérez del Val (1996), Pinto (1983), Rutgers & Norris (1972), Snow (1978), Thiollay (1985).

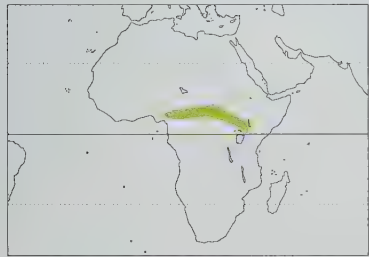

9. White-crested Turaco

Tauraco leucolophus

French: Touraco à huppe blanche **German:** Weißhaubenturako **Spanish:** Turaco Crestiblanco

Taxonomy. *Corythaix leucolophus* Heuglin, 1855, Bahr el Abiad, upper White Nile, southern Sudan. Monotypic.

Distribution. Extreme SE Nigeria, N Cameroon (Adamawa Plateau) E across S Chad and N Central African Republic to SW & S Sudan, NE Zaire, N & C Uganda and W Kenya.

Descriptive notes. c. 40 cm; male 200-225 g, female 198-226 g. Unmistakable, with pure white crest, cheeks and neck contrasting sharply with glossy violaceous blue-black lores, forehead, forecrown and area behind eyes; narrow line under eye black; throat pale greenish; mantle and breast grass-green, lower back, folded wings, rump and tail glossy violet-blue; belly and undertail-coverts blackish; primaries and outer secondaries crimson with blackish tips; eye dark brown, eyelid and bare orbital skin scarlet; bill yellow, pale greenish at base; legs and feet dark brownish black. Immature similar to adult.

Habitat. Riverine gallery forest and wooded savannas, particularly where there is an abundance of creepers and hanging foliage. Occurs from 100 m up to 2200 m.

Food and Feeding. Primarily fruits and berries, but also flowerheads, and some snails.
Breeding. Breeds Aug in Nigeria, May in Central African Republic, Apr onwards in Zaire, May-Jun in Uganda. Nest a flimsy saucer-shaped platform of intertwined dry sticks and twigs some 3-7 m above ground, often in quite open acacia-like tree. Lays 2 dull white, rounded eggs; incubation 22-23 days, by both sexes.

Movements. Although largely sedentary throughout its range, it will frequently venture away from the thicker gallery forest into the adjacent savannas, particularly when certain trees are in fruit.

Status and Conservation. Not globally threatened. CITES II. Fairly common in the Upper Nile regions of N Uganda and S Sudan, and locally common in W Kenya.

Bibliography. Bannerman (1933, 1953), Britton (1980a), Cave & Macdonald (1955), Chapin (1939), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fry *et al.* (1988), Green (1990), Jackson & Selater (1938), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1957, 1970), Nikolaus (1987), Rutgers & Norris (1972), Short *et al.* (1990), Snow (1978), Zimmerman *et al.* (1996).

10. Bannerman's Turaco

Tauraco bannermani

French: Touraco doré **German:** Bannermanturako **Spanish:** Turaco de Bannerman

Taxonomy. *Proturacus bannermani* Bates, 1923, Bango Mountains, north of Kumbo, Cameroon. Forms a superspecies with *T. erythrolophus*. Monotypic.
Distribution. Bamenda-Bango Highlands of NW Cameroon.

Descriptive notes. c. 43 cm; 200-250 g. Adult has grey lores, chin and cheeks; forehead dark grey with crimson wash; crown, crest and nape crimson (feather bases greenish grey); sides of neck and breast green; mantle, lower back, wing-coverts and tertials golden-green; rump blackish, glossed with green; uppertail-coverts and tail glossy purplish blue, outer edges of rectrices green; primaries and outer 3 secondaries crimson with dark brown tips; belly and undertail-coverts black with greenish wash; heavy, powerful bill yellow with dark red culmen and exposed nostrils; eyes hazel-brown, eyelids red; legs and feet black.

Habitat. Canopy and middle stratum of montane forest. Reported to be able to survive in damaged secondary forest, provided sufficient tall fruiting trees remain. From 1700 m to 2950 m.

Food and Feeding. Primarily fruits and berries of *Podocarpus milanjensis*; also figs.

Breeding. Breeds Mar-Jun, in early rainy season. Nest a flimsy platform of twigs, well hidden in thickest part of an isolated tree or bush, among a tangle of creepers, or in the thick foliage on outer branches, at 1.5-10 m above ground in open forest or along forest edge. Usually 2 white eggs; incubation by both sexes, starting soon after first egg laid.

Movements. Sedentary throughout range.
Status and Conservation. VULNERABLE. CITES I. Although not yet considered globally endangered, this is a vulnerable species and one of the most threatened birds in Africa. Currently under very severe threat from forest clearance, with its habitat reduced by half in the period 1965-1985, and is likely to survive only if the remaining forests on Mt Oku and Mt Ijim are safeguarded. Intensive conservation work is now being directed towards this area by BirdLife International and its Mt Kilum Forest Project.

Bibliography. Bannerman (1933, 1953), Bannerman & Bates (1924), Bates (1923, 1927), Collar & Andrew (1988), Collar & Stuart (1985), Collar *et al.* (1994), Dowsett & Forbes-Watson (1993), Eizenraut (1973), van den Elzen (1975), Ferguson-Lees & Faull (1992), Fotso (1993, 1996), Fry *et al.* (1988), Louette (1981), Mackworth-Praed & Grant (1970), Macleod & Parrott (1991, 1992), Serle (1950b), Snow (1978), Stuart & Jensen (1986), Young, J. (1995).

11. Red-crested Turaco

Tauraco erythrolophus

French: Touraco pauline **German:** Rotschopfturako **Spanish:** Turaco Crestirrojo

Taxonomy. *Opaethus erythrolophus* Vieillot, 1819, Angola. Forms a superspecies with *T. bannermani*. Monotypic.

Distribution. W & C Angola from lower R Congo S to Chingoroi area, and E to at least Malanje and upper R Cuanza. Sympatric with *T. schalowi* in many areas.

Descriptive notes. c. 40-43 cm; 210-325 g. Differs from *T. bannermani* only in having some of crimson crest feathers white-tipped, and more extended crimson on back of neck; lores, chin and cheeks white; bill smaller and all-yellow, with pale greenish at base in some birds; nostrils round, not oval, and covered by feathers.

Habitat. Evergreen and riverine gallery forests from R Congo in W of range, and extending E to Bie Province in the *Brachystegia* zone; also reported in ecotone between forest and *Brachystegia* woodland near N'dalatando.

Food and Feeding. Virtually unknown. Crop of one specimen from Chingoroi contained

seeds of Rubiaceae. Species presumably also takes fruits and berries.

Breeding. Undescribed.
Movements. Unknown. Presumably sedentary within its known range and habitat.

Status and Conservation. Not globally threatened. CITES II. A very little-known species, reportedly common in forest at Gabela and in N'dalatando district, and in gallery forest along the R Cuanza and in Quissama National Park. Endemic to war-torn Angola, where clearance of submontane forests on Angola Escarpment and continuing degradation of broadleaf woodlands present a possible threat to its numbers.

Bibliography. Arena (1982), Bannerman (1933, 1953), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Hall (1960), Mackworth-Praed & Grant (1962, 1970), Meise (1955), Pinto (1983), Rutgers & Norris (1972), Snow (1978), Traylor (1963).

12. Hartlaub's Turaco

Tauraco hartlaubi

French: Touraco de Hartlaub **German:** Seidenturako **Spanish:** Turaco de Hartlaub
Other common names: Black-crested Turaco

Taxonomy. *Corythaix hartlaubi* Fischer and Reichenow, 1884, Mt Meru, northern Tanzania. Forms a superspecies with *T. leucotis*. Monotypic.

Distribution. Centred around Kenyan Highlands, extending into E Uganda at Mts Morongole, Moroto, Kadam, Debasien and Elgon, and into N Tanzania at Loliendo, Longido, Mt Meru and Mt Kilimanjaro, North and South Pares and W Usambaras.

Descriptive notes. 43 cm; male 210-270 g, female 195-275 g. Adult has forehead, rounded bushy crest and nape glossy blue-black, with a prominent white patch in front of eye, itself separated from a white line extending from gape to ear-coverts by a black loreal patch and a narrow black line immediately beneath eye; chin, cheeks, neck, mantle, throat and breast green; lower back, folded wings and tail deep violet-blue; rump blue-black; greater part of primaries and outer secondaries crimson; thighs and belly dull blackish, washed with green; eyes brown; orbital ring and bare skin behind eye red; bill dark red; legs and feet black. Immature similar to adult.

immature similar to adult.

Habitat. Montane evergreen forest at 1500-3200 m; in C Kenya, also occurs in well-timbered suburban gardens around Nairobi and Nanyuki.

Food and Feeding. Primarily fruits and berries, particularly *Chaetacme*, *Elaeodendron*, *Euclea*, *Trema*, *Duranta*, *Rawsonia*, *Podocarpus*, *Teclea*, *Viola* and *Olinea*; also eats the large, poisonous fruits of *Acokanthera longiflora*. In Nairobi suburbs frequently feeds on exotic fruits such as *Cotoneaster*, while at other times will also take caterpillars, moths and beetles.

Breeding. Breeds Apr-Dec, with peaks coinciding with periods of high rainfall. Nest a shallow platform of loosely interlaced twigs, sometimes lined with finer twigs, some 3-8 m above ground among thick tree foliage. Usually 2 round ovate, dull white eggs; incubation 16-18 days, by both sexes. Newly hatched chicks are covered in black down, and are fed on caterpillars and regurgitated fruit pulp; at 17-18 days able to climb all over the nest tree, rarely lingering in the nest itself, and can fly at c. 28 days. Initial nests commonly fail, and pairs soon nest again.

Movements. Sedentary throughout its range.

Status and Conservation. Not globally threatened. CITES II. Fairly common everywhere within its range, and still found to be locally abundant in many areas above 2000 m. Some populations in N Tanzania appear to have suffered a significant impact as a consequence of indiscriminate trapping for the bird-export trade.

Bibliography. Bennun & Njoroge (1996), Britton (1980a), Brown & Britton (1980), Dowsett & Forbes-Watson (1993), Friedmann (1930a), Fry *et al.* (1988), Jackson, C. (1997), Jackson, F.J. & Sclater (1938), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1957), Rutgers & Norris (1972), Short *et al.* (1990), Snow (1978), van Someren (1956), Zimmerman *et al.* (1996).

13. White-cheeked Turaco

Tauraco leucotis

French: Touraco à joues blanches **German:** Weißohrturako **Spanish:** Turaco Cariblanco

Taxonomy. *Corythaix leucotis* Rüppell, 1835, northern Ethiopia. Forms a superspecies with *T. hartlaubi*. Two subspecies recognized.

Subspecies and Distribution.

T. l. leucotis (Rüppell, 1835) - Ethiopian Highlands from SW Arussi, Shoa and Sidamo Provinces, W to the Boma Plateau in SE Sudan, and N to Eritrea.

T. l. donaldsoni (Sharpe, 1895) - SC Ethiopian Highlands in N Harrar, Arussi and N Bale.

Descriptive notes. 42-43 cm; 200-315 g. Adult has forehead, neck, throat, breast and upperparts green; rounded crest and hindcrown glossy dark blue, with a large circular white loreal patch, a small black band (often very faint) extending under eye from gape to ear-coverts, and a prominent but variable crescentic white patch on side of neck; lower back, folded wings and tail greyish blue, rump grey-blue; primaries and outer secondaries crimson; thighs and belly dull blackish; eye brown, with bright red wattled orbital ring; bill red, with greenish base around nostrils largely concealed by feathers; legs and feet black. Immature rather similar to adult. Race *donaldsoni* has hindcrown and crest dull crimson. Nominate birds in Eritrea and areas W of the Rift Valley have upper back and wing-coverts bluer, and they also have large conspicuous neck patches, while many birds E of the Rift are brighter and greener, with less white on sides of neck.

Habitat. Typically occurs in montane *Podocarpus* and juniper (*Juniperus*) forest from 2200 m up to 3200 m, but can be found as low as 850 m in the Omo Valley; also in tall gallery trees and thick bush along watercourses. In Eritrea occurs in almost any type of dense woodland, except acacia, ranging down to 900 m.

Food and Feeding. Primarily fruits and berries of *Podocarpus* and juniper trees.

Breeding. Breeds in Apr in Eritrea, and in Jun-Nov in Ethiopia. Nest is a rather thick platform of dry twigs, very loosely constructed, with a slight depression at top, placed some 7-10 m above ground. Lays 2 off-white eggs; incubation 22-23 days, by both sexes. Newly hatched chicks are covered in black down; at 18-19 days they begin to crawl about in branches around nest, and are able to fly at 25-26 days.

Movements. Largely sedentary throughout its range.

Status and Conservation. Not globally threatened. CITES II. Fairly common in many areas of *Podocarpus* and juniper forest in Ethiopian Highlands above 2400 m. No known threats at present, but any destruction of this species' forest habitats could lead to serious local depletion of its numbers.

Bibliography. Borghesio (1997b), Cave & Macdonald (1955), Cheesman & Sclater (1935), Deshayes (1975), Dowsett & Forbes-Watson (1993), Duckworth *et al.* (1992), Énard & Prévost (1971), Evans (1984), Everitt (1965), Foxall & Burton (1975), Friedmann (1930a), Fry *et al.* (1988), Hewston (1984), Mackworth-Praed & Grant (1957), Martin (1973), Moltoni (1939), Nikolaus (1987), Rutgers & Norris (1972), Smith (1957), Snow (1978), Urban & Brown (1971), Wilson (1985).

14. Ruspoli's Turaco

Tauraco ruspolii

French: Touraco de Ruspoli **German:** Ruspoliturako **Spanish:** Turaco de Ruspoli
Other common names: Prince Ruspoli's Turaco

Taxonomy. *Turacus ruspolii* Salvadori, 1896, southern Ethiopia (? Arero). Monotypic.

Distribution. Restricted to S Ethiopia around Arero, Bobela, Sokora, Neghelli and Wadera.

Descriptive notes. c. 40 cm; 200-290 g. Adult has forehead and front of crest covering nostrils greenish grey; rest of rounded bushy crest (feathers 40 mm long) is greyish white, rose-pink at base, and with a tuft of red feathers on nape; lores, area under eye, and ear-coverts bright yellowish green; chin and throat greyish green; neck, breast and upper back moss-green; lower back, folded wings and tail greyish blue; primaries and outer secondaries crimson; belly and thighs blackish; eye brown, with bare orbital skin and wattle above eye vermilion-red; bill vermilion-red; legs and feet black. Juvenile undescribed.

Habitat. While occurring in juniper (*Juniperus*) forest with dense evergreen undergrowth near Arero and Wadera, it is thought to favour drier forest margins, acacia-conifer woodland, and mixed broadleaf scrub with scattered *Gardenia* and *Ficus*. From 1250 m to 1860 m.

Food and Feeding. Primarily fruit, with figs (*Ficus*), *Juniperus procera* and *Podocarpus gracilior* as main food plants.

Breeding. No definite information available. Recently reported by local people to breed Dec-Feb near Genale R (Sidamo Province); investigation required.

Movements. Believed to undertake regular short-range movements from wetter juniper forests and their margins to surrounding drier woodland.

Status and Conservation. ENDANGERED. CITES II. Although listed as being a globally Endangered species, with its survival threatened by continuing degradation and loss of habitat within its restricted range, recent surveys suggest that it is actually much more common and widespread than was believed until quite recently. Field work has also shown that it prefers drier habitats such as acacia-conifer woodland, rather than the wetter juniper forests, and that it can tolerate human presence and activities within its habitat.

Bibliography. Ash & Gullick (1989), Benson (1942, 1945), Borghesio (1997a, 1997b), Coles & Woolham (1996), Collar & Andrew (1988), Collar & Stuart (1985), Collar *et al.* (1994), Dellelegn (1991), Dowsett & Forbes-Watson (1993), Énard & Prévost (1970), Fishpool *et al.* (1996), Fry *et al.* (1988), Gilbert (1971), Hall & Moreau (1962), Mackworth-Praed & Grant (1957), Robertson (1995, 1996), Salvadori (1913), Shuker (1993), Snow (1978), Sørensen *et al.* (1997), Syvertsen & Dellelegn (1991), Urban (1980), Urban & Brown (1971).

15. Purple-crested Turaco

Tauraco porphyreolophus

French: Touraco à huppe splendide **German:** Glanzhaubenturako **Spanish:** Turaco Crestimorado
Other common names: Violet-crested Turaco, Purple-crested Lourie

Taxonomy. *Corythaix porphyreolophus* Vigors, 1831, Durban.

Placed in the genus *Musophaga* by some authorities; formerly awarded monotypic genus *Gallirex*. Races intergrade in Zambezi Valley. Two subspecies recognized.

Subspecies and Distribution.

T. p. chlorochlamys (Shelley, 1881) - SE Kenya through Tanzania, Burundi and Rwanda to Zambia (Victoria Falls, Luano and Luangwa Valleys), Malawi and N Mozambique.

T. p. porphyreolophus (Vigors, 1831) - Zimbabwe and Mozambique S to E Transvaal and Natal.

Descriptive notes. 42-46 cm; male 225-303 g, female 218-328 g. Adult has forehead, supercilary area, cheeks and ear-coverts glossy emerald-green; rounded crown, crest and nape iridescent dark violet-purple; lower cheeks, chin, throat and neck green; upper back and breast green, washed with rose-pink; lower back, and wing-coverts (except lesser) greyish blue; rump dull blue-black; uppertail-coverts, tail and inner secondaries glossy violet-blue with greenish wash; primaries and outer secondaries crimson with dark brownish edges and tips; belly and thighs pale bluish slate; eyes brown, with bare orbital skin scarlet; bill black; legs and feet blackish. Juvenile similar to adult, but crimson in wings duller and less extensive. Race *chlorochlamys* lacks pink wash to upper back and breast; bare scarlet skin around eye typically extends farther forward; belly and thighs dull greenish grey; secondaries and tail lack greenish tones.

On following pages: 16. Ruwenzori Turaco (*Ruwenzorornis johnstoni*); 17. Violet Turaco (*Musophaga violacea*); 18. Ross's Turaco (*Musophaga rossae*); 19. Grey Go-away-bird (*Corythaixoides concolor*); 20. Bare-faced Go-away-bird (*Corythaixoides personatus*); 21. White-bellied Go-away-bird (*Corythaixoides leucogaster*); 22. Western Grey Plantain-eater (*Crinifer piscator*); 23. Eastern Grey Plantain-eater (*Crinifer zonurus*).

Habitat. Typically in moist woodland, evergreen thickets and riparian growth, but also frequents coastal forest, *Brachystegia* woodland and, in some areas, suburban parks, gardens and exotic plantations. Occurs from sea-level up to 1850 m.

Food and Feeding. Frugivorous. Favourite fruits include *Ficus sycamorus*, *Ficus soldanella*, *Strychnos decussata*, *Strychnos potatorum*, *Lannea stuhlmanni* and *Berchemia discolor*; also takes *Ekebergia*, *Vitex*, *Syzygium*, *Diospyros*, *Maesa*, *Rhus*, *Crocoxylon*, *Duranta*, *Feretia*, *Pseudocadia*, *Olea*, *Celtis*, *Mimusops*, *Ziziphus*, *Rhoicissus*, *Antidesma*, *Chaetacme* and *Cassine*, as well as several other species of *Ficus*, and buds of *Capparis*. In southern Africa, readily feeds at birdtables on paw-paw, guava, mulberries and maize-meal. In captivity, has been recorded consuming 134 g of food daily.

Breeding. Breeds Jan-Mar in Tanzania, Jan in Malawi, Dec in Zambia, Oct-Jan in Zimbabwe, Nov-Dec in S Africa. Nest a flimsy unlined platform of interlacing twigs 3-9 m above ground, well concealed in a tree among matted creepers or dense parasitic growth, often in isolated thicket or at edge of forest. Lays 2-3 rounded, glossy white eggs, laying interval 1-2 days; incubation 22-23 days, by both sexes. On hatching, young are covered with thick greyish brown down; brooded almost continuously for the first week, fed by both parents by regurgitation, parents swallowing chicks' faeces immediately they appear; chicks become active at c. 3 weeks, moving out of nest to climb about in nest tree, and make first flight at c. 38 days.

Movements. Limited movements appear to occur, as birds are often liable to turn up at fruiting trees in areas from which they are usually absent; however, precise patterns unclear. Also, in association with the rains, there may be some seasonal dispersal away from riparian growth and into surrounding woodland or thornbush.

Status and Conservation. Not globally threatened, CITES II. An essentially resident species which, although localized, is quite common in several parts of its southern African range. Owing to severe loss of habitat and indiscriminate trapping in Tanzania, however, subspecies *chlorochlamys* has become a near-threatened taxon within its E African range, where only a few small isolated groups now survive.

Bibliography. Benson & Benson (1977), Benson *et al.* (1971), Britton (1980a), Clancey (1996), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Ginn *et al.* (1989), Jackson & Selater (1938), Jarvis & Currie (1979), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1957, 1962), Maclean (1993), Newman (1996), Raison (1992), Rowan (1983), Rutgers & Norris (1972), Short *et al.* (1990), Sinclair (1987), Sinclair & Whyte (1991), Snow (1978), Wood, J. (1992), Zimmerman *et al.* (1996).

Genus *RUWENZORORNIS* Neumann, 1903

16. Ruwenzori Turaco

Ruwenzorornis johnstoni

French: Touraco du Ruwenzori **German:** Kammschnabelturako **Spanish:** Turaco del Ruwenzori
Other common names: Johnston's Turaco

Taxonomy. *Gallirex johnstoni* Sharpe, 1901, Mt Ruwenzori. Placed in the genus *Musophaga* by some authorities. Proposed race *bredoi*, originally described from W shore of L Tanganyika, is now considered synonymous with nominate. Two subspecies recognized.

Subspecies and Distribution.

R. j. johnstoni (Sharpe, 1901) - Ruwenzori Mts in NE Zaire and SW Uganda; also E Zaire at Mulu (NW of L Edward), and at Mt Kabobo (at NC part of W shore of L Tanganyika).

R. j. kivuensis Neumann, 1908 - montane forests of Kivu Highlands of E Zaire, Virunga volcanoes and Nyungwe Forest of Rwanda and Burundi, and SW Uganda (Bwindi National Park).

Descriptive notes. c. 45 cm; 211-259 g. Adult has forehead and forecrown glossy emerald-green; hindcrown with short crest glossy purplish blue or emerald-green (varying with light direction); nape dull crimson; chin and throat glossy dark violet (usually appearing black), sharply demarcated from green cheeks and neck; upper back and breast green, with peachy-red patch on foreneck and breast; lower back, wing-coverts and tail deep violet-blue, shading to black on rump; primaries and outer secondaries crimson with dark tips; belly, thighs and undertail-coverts grey; bill pale grey-green often with bluish wash and base

finely stippled purplish red, nostrils to tip black; shape distinctive, with high, almost straight culmen rising to narrow bony ridge between eyes; eye dark brown, with narrow red eyelids; large bare patch behind, under and in front of eye is mostly bright lemon-yellow, but scarlet at rear and lower edge in some individuals; legs and feet blackish. Immature undescribed. Race *kivuensis* lacks bare facial patch, having this area fully feathered bright emerald-green.

Habitat. Montane forests, generally favouring those areas dominated by bamboo and *Podocarpus*. From 2000 m to 3600 m.

Food and Feeding. Fruits and berries, notably those of *Ficus*, *Galiniera*, *Maesa*, *Musanga*, *Olea*, *Olinia*, *Podocarpus latifolius*, *Polyscias*, *Prunus*, *Rapanea*, *Rutidea*, *Schefflera* and *Syzygium*. Also takes insects, snails, slugs and leaves of lianas and epiphytes.

Breeding. Breeds May in Uganda, May-Nov in E Zaire, Oct-Nov in Rwanda. Nest a small platform of sticks, much like that of a pigeon (Columbidae), some 3-5 m above ground, often in a clump of bamboo. Lays 1-2 dull greyish white eggs; incubation by both sexes. Young bird is covered in blackish down, with bare skin around eyes bluish, but pinkish around ear-coverts; bill blackish at tip, pinkish basally; legs greyish.

Movements. Sedentary throughout its range.

Status and Conservation. Not globally threatened. Although confined to the montane forests of the Albertine Rift, this distinctive species appears to be fairly common throughout its rather restricted range.

Bibliography. Britton (1980a), Chapin, J.P. (1939), Chapin, R.T. (1978), Dowsett (1990), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Jackson & Selater (1938), Lippens & Wille (1976), Mackworth-Præd & Grant (1957, 1970), Prigogine (1960), Rutgers & Norris (1972), Short *et al.* (1990), Snow (1978), Sun & Moermond (1997).

Genus *MUSOPHAGA* Isert, 1789

17. Violet Turaco

Musophaga violacea

French: Touraco violet **German:** Schildturako **Spanish:** Turaco Violáceo
Other common names: Violet Plantain-eater

Taxonomy. *Musophaga violacea* Isert, 1789, Accra, Ghana.

Forms a superspecies with *M. rossae*. Birds from E end of range formerly awarded separate race, *savannicola*. Monotypic.

Distribution. S Senegambia and Guinea E to N Nigeria and NW Cameroon, extending S to the coast in Ivory Coast, Ghana and Togo, but not in Sierra Leone, Liberia or Nigeria; also an apparently isolated population in extreme S Chad and N Central African Republic.

Descriptive notes. c. 50 cm; c. 360 g. Adult has crown and nape crimson, the feathers short and velvety; ear-coverts silky white; chin, throat and neck glossy violaceous blue-black; upperparts and wing-coverts violet-blue; tail violet-blue, washed with green; breast to upper belly violaceous blue-black, strongly washed with moss-green; lower belly and thighs matt black; primaries and outer secondaries crimson, tipped brown; bill red, with convex yellow frontal shield or casque extending back on forehead to a point level with rear edge of eyes; eyes dark brown, with bare orbital ring red; bare loreal patch and area around eye bright red; legs and feet

black or greenish black. Juvenile rather "crow-like", lacking conspicuous head and bill colours of adult: bill blackish with swollen base but without frontal shield, lores and small area under eyes naked and dark, rest of head matt black, with remainder of body plumage similar to adult.

Habitat. Typically in gallery forest, forest edge and fringing forests along watercourses in mesic or arid savannas; also occasionally in tall, well-timbered suburban parks and gardens. Sea-level to 1000 m.

Food and Feeding. Primarily fruits, berries and seeds, with figs (*Ficus*) favoured at all times.

Breeding. Breeds in Apr in Senegambia, Jun-Oct in Nigeria. Nest a fragile pigeon-type platform of sticks and twigs, some 6 m above ground in a leafy tree. Lays 2 oval, greyish white eggs, not glossy; incubation 25-26 days, by both sexes.

Movements. Very little precise information available. Species is probably sedentary, or at least mainly so; however, it appears to be vagrant to Sierra Leone, where only two records, one of them from 19th century.

Status and Conservation. Not globally threatened. Locally common in several areas, and possibly even very common in some places, but no detailed data on numbers. Populations in Guinea, Sierra Leone, Liberia and Ghana are heavily impacted by indiscriminate trapping for bird-export trade. CITES III in Ghana.

Bibliography. Bannerman (1933, 1953), Bent (1988), Bent & Corbett (1993), Cheke & Walsh (1996), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fry *et al.* (1988), Giraudeau *et al.* (1988), Gore (1990), Green (1990), Grimes (1987), Jensen & Kirkeby (1980), Lamarche (1980), Louette (1981), Mackworth-Præd & Grant (1970), Malbrant (1952), Morel & Morel (1990), Rutgers & Norris (1972), Snow (1978), Thiollay (1985), Wells & Walsh (1969).

18. Ross's Turaco

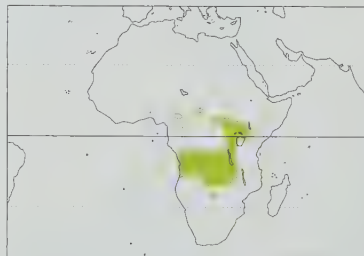

Musophaga rossae

French: Touraco de Lady Ross **German:** Rossturako **Spanish:** Turaco de Ross
Other common names: Ross's Lourie, Lady Ross's Violet Plantain-eater/Turaco

Taxonomy. *Musophaga Rossae* Gould, 1852, Angola.

Forms a superspecies with *M. violacea*. Monotypic.

Distribution. Widely distributed from NE & E Zaire, S Sudan, Uganda, W Kenya, NW Tanzania, Rwanda and Burundi to all of S Zaire, N & E Angola and N Zambia; also isolated populations in NE Gabon, Cameroon, N Central African Republic, and at one or two localities in the Caprivi Strip and in the Okavango Delta in NW Botswana. May be sympatric with *M. violacea* in N Central African Republic and near Galim in C Cameroon.

Descriptive notes. 51-54 cm; male 390-444 g, female 395-398 g. Adult has crown dark crimson, with feathers forming a short, erectile crest; chin, throat, nape and neck glossy blue-black; upperparts, breast, wing-coverts and tail dark violaceous blue; belly and thighs blackish; primaries and outer secondaries crimson, tipped brown; bill yellow, with convex yellow frontal shield or casque extending back on forehead to a point level with front edge of eyes (lower mandible and hind part of casque occasionally reddish); eye brown; bare loreal skin and area above, below and behind eyes bright yellow; legs and feet black. Juvenile has

bill and bare skin around eyes blackish, yellow culmen but no frontal shield, forehead feathering black, and crown black with red central patch.

Habitat. Canopy of evergreen gallery and riparian forest, but also in *Mavunda* forest and *Marquesia* thickets in Zambia, and in *Euphorbia* bush and on occasions deciduous thickets and *Brachystegia* woodland in Botswana and Caprivi Strip. Typically from sea-level to 1750 m, but also to 2500 m on border between S Sudan and NE Uganda.

Food and Feeding. Wild and cultivated fruits and berries, including *Ficus*, *Musanga*, *Bridelia*, *Beilschmiedia*, *Cissus* and guava; also flowers of *Grevillea*, young shoots, and termites and snails.

Breeding. Breeds May-Nov in W Kenya, all year round (except Sept) in Uganda, Sept-Nov in Zambia, and Dec in Zaire. Nest a pigeon-type platform of sticks up to 60 cm long, lined with

smaller twigs, and built by both sexes 2-16 m above ground among thick foliage, mistletoe or creepers, often in an isolated tree. Lays 1-2 almost cylindrical creamy-white eggs; incubation 24-26 days, by both sexes, changeovers occurring 3-4 times per day. Newly hatched young are covered in woolly, dark brown down; brooded for at least 8 days, when first quills begin to appear, and at 21 days are well feathered, though head is still mainly downy, while crest starts to develop at 23-30 days; leave nest around day 24, hopping about on nearby branches, before leaving the nest tree permanently at c. 26-31 days with parents in close attendance.

Movements. Frequently wanders to fruiting trees in areas away from its normal haunts. Otherwise more or less sedentary.

Status and Conservation. Not globally threatened. Common in Uganda, and reported as frequent to common in general throughout much of its range. The fact that this species' discovery in NE Gabon in mid 1980's occurred only after earlier intensive survey work in the area had failed to record it indicates that, like other members of the family, it may well be overlooked in some places. Occasional records of nests being raided by blue monkeys (*Cercopithecus mitis*) and by snakes such as the forest cobra (*Naja melanoleuca*), in W Kenya.

Bibliography. Subfamily CRINIFERINAE

Genus *CORYTHAIXOIDES* A. Smith, 1833

19. Grey Go-away-bird

Corythaixoides concolor

French: Touraco concolore **German:** Graulärmvögel **Spanish:** Turaco Unicolor
Other common names: Grey Lourie

Taxonomy. *Corythaix concolor* A. Smith, 1833, inland of Durban.

Forms a superspecies with *C. personatus*. Races *pallidiceps* and *bechuanae* intergrade in W Botswana. Two additional forms (*chobiensis* and *cuanhamae*) are considered doubtfully separable from *bechuanae*. Four subspecies currently recognized.

Subspecies and Distribution.

C. c. molybdophanes (Clancey, 1964) - NE Angola through S Zaire, Zambia and N Malawi to S Tanzania and adjacent areas of N Mozambique.
C. c. pallidiceps (Neumann, 1899) - W Angola S to Namibia, extending seasonally to W Botswana.
C. c. bechuanae (Roberts, 1932) - S & SE Angola and NE Namibia through Botswana and the Caprivi Strip to SW Zambia, the Zimbabwe Plateau, and N & W Transvaal.
C. c. concolor (A. Smith, 1833) - S Malawi and N Mozambique S to E Transvaal, E Swaziland and E Zululand.

Descriptive notes. 47-50 cm; male 221-299 g, female 202-305 g. Adult has entire head and body warm smoky-grey, palest around eyes and on belly, and darkest on chin, throat, remiges and primary coverts; tail darkens towards tip, which is dark brown; breast has a suffusion of greyish olive or olive-green, though generally this is barely noticeable in the field; feathers of crown are elongated and partly decomposed, forming a conspicuous and slightly shaggy crest 60-75 mm in length that can be raised or depressed at will; when flattened, it projects well beyond back of head; eye brown; bill, legs and feet black. Juvenile has a shorter crest and a buffy tinge to its plumage. Races differ only moderately: *pallidiceps* palest, with breast suffusion yellowish and more extensive; *molybdophanes* lacks olive suffusion on breast; *bechuanae* darkest, and generally has longest crest (to 75 mm).

Habitat. Typically in thornbush, savanna and riparian woodlands, generally showing a preference for woodlands dominated by or including acacias; frequently recorded in suburban parks and gardens. Highly dependent on water in all areas. Sea-level to 1500 m, but occasionally to 2200 m in E Zimbabwe.

Food and Feeding. Fruits of *Ficus*, *Viscum*, *Loranthus*, *Diospyros*, *Lannea*, *Ziziphus*, *Salvadora*, *Grewia*, *Euclea*, *Dovyalis*, *Bridelia*, *Pseudocadia*, *Strychnos*, *Coroneaster* and *Melia*; also a wide variety of cultivated fruits up to the size of a peach. Eats pods of *Acacia*; probes flowers for nectar, and eats whole flowers of *Aloe*, *Acacia robusta*, *Acacia karroo*, *Erythrina*, *Sclerocarya* and *Bauhinia*; also leaf buds and leaves of *Acacia robusta*, *Melia* and *Ficus capensis*. Frequently comes to ground to drink and to eat termites.

Breeding. Breeds Jul-Aug in Angola, Apr-Nov in Malawi, Aug-Sept in Zambia, Sept and Dec-Apr in Namibia, and all months in South Africa and Zimbabwe. Nest a flimsy, pigeon-type platform of sticks, c. 18-24 cm in diameter, built by both sexes 3-20 m (generally c. 5 m) above ground and usually in an acacia, but on occasions in non-thorny trees, clumps of mistletoe or among dense matted creepers in a tree. Usually 3 eggs (1-4), white or pale greyish blue and slightly glossy, laid at 2-day intervals; incubation 26-28 days, by both sexes, and generally by female only at night; hatching staggered, with last egg hatching between 18 hours and 3 days after first. Newly hatched young are covered in dense brown or greyish brown down; fed by regurgitation; become very active at 2-3 weeks, clambering awkwardly around branches near nest, and leaving it permanently on day 23; able to fly at c. 4 weeks, and still fed by parents up to 40-45 days, but independent of them at c. 7 weeks.

Movements. While there is much local wandering in relation to fluctuating food and water supplies, no regular migratory movements have been recorded.

Status and Conservation. Not globally threatened. Throughout much of its range this is a common species, often found in flocks of up to 30 at drinking and feeding sites, or perched near tops of tall

thorn trees. In parts of S Africa, it is considered a pest in fruit-growing areas and gardens and is consequently persecuted; large numbers were formerly killed for food, and this practice continues in certain places. Frequently a victim of birds of prey, especially Bateleur (*Terathopius ecaudatus*) and African Goshawk (*Accipiter tachiro*), but also preyed upon by other diurnal raptors.

Bibliography. Aarts (1983), Babich (1982), Benson & Benson (1977), Benson *et al.* (1971), Braine *et al.* (1983), Britton (1980a), Clancey (1964a, 1996), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Ginn *et al.* (1989), Lippens & Wille (1976), Mackworth-Præd & Grant (1957, 1962, 1970), Maclean (1993), Newman (1996), Penry (1979a, 1994), Pinto (1983), Roles (1970), Rowan (1983), Rutgers & Norris (1972), Sinclair (1987), Sinclair & Whyte (1991), Snow (1978), Stevenson (1982), Young (1976).

20. Bare-faced Go-away-bird

Corythaixoides personatus

French: Touraco masqué **German:** Nacktkehl-Lärmvögel **Spanish:** Turaco Enmascarado
Other common names: Black-faced Lourie

Taxonomy. *Chizærhis personata* Rüppell, 1842, Ethiopia.

Forms a superspecies with *C. concolor*. Two subspecies recognized.

Subspecies and Distribution.

C. p. personatus (Rüppell, 1842) - Ethiopian Rift Valley from Dire Dawa and Ankober S to I. Abaya and Yavello.

C. p. leopoldi (Shelley, 1881) - S Uganda, Rwanda, Burundi, SW Kenya and Tanzania S to N Malawi, NE Zambia and SE Zaire.

Descriptive notes. c. 48 cm; 210-300 g. Adult has forepart of face to behind eyes, and chin and upper throat virtually bare of feathers, appearing dark brown; forehead and rather lax crest ashy-brown washed with green, crest 60 mm long; breast pale sage-green, back, wings and tail smoky-grey with slightly scaled effect; upper belly dark pinkish brown, shading to greenish on undertail-coverts; underwing and undertail pale greenish; eye brown; bill, legs and feet black. Juvenile similar to adult, but plumage fluffy and downy, crest dark grey-brown, upperparts tinged brown, green on breast greatly reduced. Race *leopoldi* has bare

part of face black instead of brown; crest shorter (50 mm), paler ashy-brown; sides of neck and breast white, shading to ashy-white on nape and hindneck, centre of breast sage-green; upperparts, wings and tail pale grey; belly paler pinkish brown or pinkish puce, shading to greyish on undertail-coverts; underwing and undertail also pale grey.

Habitat. Open woodland, acacia thornbush, thickets, cultivation with scattered trees, and riverine acacias. From 500 m to 1850 m, occasionally to 2000 m.

Food and Feeding. Berries of *Grewia bicolor*, also buds and seed pods of *Acacia xanthophloea*.

Breeding. Breeds Mar in Ethiopia, May and Sept-Nov in S Uganda, May-Oct in Tanzania, and Oct in N Malawi. Nest a shallow platform of loosely interwoven sticks, sometimes lined with rootlets and dry grass, c. 5 m above ground in a fork or near the top of an acacia tree. Lays 2-3 round, glossy white eggs; incubation by both sexes.

Movements. Largely sedentary throughout its range.

Status and Conservation. Not globally threatened. No figures available, but species is locally common in SW Kenya and over much of Tanzania.

Bibliography. Benson & Benson (1977), Benson *et al.* (1971), Britton (1980a), Dowsett & Forbes-Watson (1993), Duckworth *et al.* (1992), Friedmann (1930a), Fry *et al.* (1988), Jackson & Selater (1938), Johnstone-Stewart & Heigham (1982), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Præd & Grant (1957, 1962, 1970), Newman *et al.* (1992), Short *et al.* (1990), Snow (1978), Urban & Brown (1971), Zimmerman *et al.* (1996).

21. White-bellied Go-away-bird

Corythaixoides leucogaster

French: Touraco à ventre blanc **German:** Weißbauch-Lärmvögel **Spanish:** Turaco Ventriblanco

Taxonomy. *Chizærhis leucogaster* Rüppell, 1842, southern Ethiopia.

Sometimes placed in the monospecific genus *Crimiferoides*. Monotypic.

Distribution. Restricted to acacia savannas in E & NE Africa: NW, C & S Somalia, Ethiopia (W to the Rift Valley), S Sudan, NE Uganda (Karamoja and Teso), N & E Kenya and S through the eastern plateau of Tanzania (W to Tabora, S to Ruaha National Park).

Descriptive notes. c. 50 cm (tail 24-25 cm); male 170-225 g, female 225-250 g. Adult grey, with white belly and undertail-coverts; a stiff, pointed, 60 mm-long brownish grey crest with dark brownish black tips rises from forehead; sides of head, chin and entire neck and breast grey, like upperparts; median and greater upwing-coverts with black ends forming partial bars on closed wing; white bases to black primaries form a conspicuous white patch in flight; tail black with broad white median band; bill blackish in male, pea-green in female (becoming yellowish when breeding); eye hazel-brown; legs and feet black. Juvenile similar to adult but browner, particularly on wing-coverts.

Habitat. Typically hot, low-lying acacia steppe and savanna with scattered trees. Occurs from sea-level up to 1700 m.

Food and Feeding. Fruits, flowers, seeds and buds of acacias, particularly favouring the young green pods of *Acacia tortilis*.

Breeding. Breeds Feb-Jul in Somalia and Ethiopia, Feb-Aug in Kenya and Tanzania, Jul-Aug in NE Uganda. Nest a rather small, frail flat structure of twigs, some 3-12 m above ground and generally in an acacia-type tree. Lays 2-3 oval, glossy, pale bluish eggs; incubation 27-28 days, by both sexes.

Movements. Largely sedentary throughout its range.

Status and Conservation. Not globally threatened. Generally common throughout its range. Although no real indication of population numbers available, observations indicate that species is

abundant in many areas. Possibly suffers some predation by birds of prey in the same way as do other birds in similar habitats, but no data have been published.

Bibliography. Ash & Miskell (1983), Britton (1980a), Brown & Britton (1980), Cave & Macdonald (1955), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Duckworth *et al.* (1992), Friedmann (1930a), Fry *et al.* (1988), Irvine (1977), Jackson & Sclater (1938), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1957), Nikolaus (1987), Short *et al.* (1990), Snow (1978), Todd *et al.* (1985, 1993), Urban & Brown (1971), Zimmerman *et al.* (1996).

Genus *CRINIFER* Jarocki, 1821

22. Western Grey Plantain-eater

Crinifer piscator

French: Touraco gris **German:** Schwarzschnanz-Lärmvogel **Spanish:** Turaco Gris Occidental
Other common names: Grey Plantain-eater

Taxonomy. *Falco piscator* Boddaert, 1783, Senegal.

Forms a superspecies with *C. zonurus*, with which has been considered conspecific. Formerly listed as *C. africanus*, on grounds that Boddaert's name was based on illustration of bird unidentifiable as present species. Monotypic.

Distribution. S Senegambia, Sierra Leone and coastal Liberia E to Central African Republic (in N almost reaching Sudan border); also disjunctly in Congo and Zaire, along R Congo S of Stanley Pool.

Descriptive notes. c. 50 cm (tail 24-25 cm).

Adult has forehead, crown, lores, chin, throat and cheeks dark brown; shaggy nuchal crest of narrow, pointed hindcrown feathers up to 45 mm long, dark brown with whitish edges; sides of neck and upper breast dark brown, washed and streaked silvery; upper back silvery-grey with dark brown spots; wing-coverts grey with dark brown shafts and spot at tip, and narrow pale grey edges; rump and uppertail-coverts grey with dark shafts; central rectrices grey, becoming dark brown at tip, rest of tail blackish brown; secondaries and primary coverts blackish brown; primaries

blackish, with central third of inner webs white; lower breast, belly, flanks and undertail-coverts white, with grey feather bases and brown shaft streaks up to 2 mm wide; bill large, strong, bright lemon-yellow with greenish base; eyes dark brown; legs and feet brownish black. Juvenile similar to adult, but crest shorter.

Habitat. All types of open wooded savanna and cultivation, from the sahelian acacia steppe to near the edge of the rainforest zone, typically from sea-level to 1300 m. In Sierra Leone, commonest in palm "bush" and derived savanna (including *Lophira* zone), and in trees at edges of open grassland or swamps.

Food and Feeding. Wild and cultivated fruits, including figs, mangoes, guavas, sapotillas, oil-palm fruits and dates; also *Cordia senegalensis*, *Azadirachta indica* and *Zizyphus mucronota*.

Breeding. Breeds Jan-Aug and Oct in Senegambia, Jan-Jun in Mali, Apr-May in Nigeria, Mar-May and Sept-Oct in Ghana, and Jan-Apr in Congo. Nest a substantial platform of thin, dry sticks, c. 30 cm in diameter and 12 cm deep, some 6-15 m above ground in a leafy tree. Lays 2-3 oval and slightly glossy greyish white or pale bluish white eggs; incubation 27-28 days, by both sexes.

Movements. Largely sedentary throughout its range.

Status and Conservation. Not globally threatened. Locally abundant in Senegambia, reaching a density of 1 bird/ha in some areas of *Acacia scorpioides* woodland. Appears reasonably common

everywhere else, although no detailed information on numbers or on any potential threats. CITES III in Ghana.

Bibliography. Ash (1990), Bannerman (1933, 1953), Chapin (1939), Cheke & Walsh (1996), Dowsett (1989), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fry *et al.* (1988), Giraudeau *et al.* (1988), Gore (1990), Green (1990), Grimes (1987), Halleux (1994), Jensen & Kirkeby (1980), Lamarche (1980, 1988), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1970), Morel & Morel (1990), Snow (1978), Thiollay (1985), Walsh *et al.* (1990).

23. Eastern Grey Plantain-eater

Crinifer zonurus

French: Touraco à queue barrée **German:** Bindenlärnvogel **Spanish:** Turaco Gris Oriental

Taxonomy. *Chizaerhis zonurus* Rüppell, 1835, Temben, Ethiopia.

Forms a superspecies with *C. piscator*, with which has been considered conspecific. Monotypic.

Distribution. Eritrea, Ethiopian Rift Valley and W highlands, S & W Sudan, N & NE Zaire S through Uganda and Rwanda to SE Zaire (R Niemba and upper R Lualaba), W Burundi, NW Tanzania E to Mwanza, Serengeti and R Malagarasi, and W Kenya from Mt Elgon S to R Mara; also disjunctly in SE Chad and N Central African Republic (where possibly sympatric with *C. piscator*).

Descriptive notes. c. 50 cm; 501-548 g. Distinguished from *C. piscator* by white in tail, scalloped (not spotted) upperparts with less conspicuous shaft streaks, unstreaked lower belly. Forehead, crown, lores and cheeks dark brown; shaggy nuchal crest of narrow, pointed hindcrown feathers up to 35 mm long, dark brown with whitish tips; sides of neck and breast dark brown, washed and streaked silvery; upper back and wing-coverts grey, feathers with dark shaft streaks, no dark spots at tip but with whole end dark, forming brownish scallops on greyish brown background; rump and uppertail-coverts grey with dark shafts;

middle third of outer tail white (conspicuous in flight), while central rectrices all greyish brown and becoming dark brown at tip; outer 4 rectrices whitish, grading to blackish brown at base, with broad blackish brown tips 50-65 mm deep; secondaries and primary coverts blackish brown; primaries blackish, with white central part of inner webs forming conspicuous wing-bar in flight; chin and throat brown, feathers of throat and upper breast tipped buffy-white; lower breast and upper belly whitish with indistinct grey-brown streaking; lower belly and vent off-white without dark streaks; bill large, greenish yellow; eyes dark brown; legs and feet brownish black. Juvenile similar to adult.

Habitat. Inhabits all types of open wooded savannas and cultivation; locally common also in many well-timbered suburban parks and gardens, particularly around Kampala and Entebbe in Uganda. Mainly below 1500 m, but occurs at up to 1900 m on Mt Elgon and in parts of Ethiopia.

Food and Feeding. Primarily fruits, including *Ficus* and *Musanga*; also flowers of *Daniellia oliveri* in West Nile Province of NW Uganda.

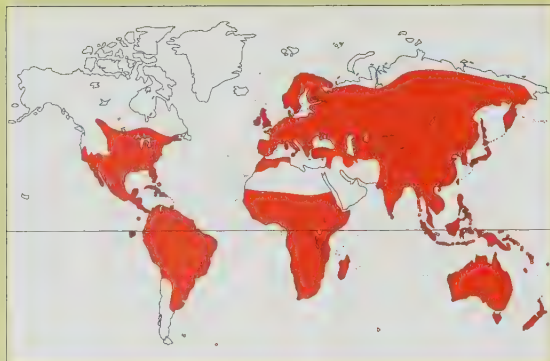

Breeding. Breeds Mar-May in Sudan, Jan-Mar in Ethiopia, Nov-Mar in Zaire, Oct in Burundi, Aug-May in W Kenya, and Mar-Apr and Aug-Jan in Uganda. Nest an untidy platform of dry twigs and sticks built near top of a tall leafy tree. Lays 2-3 white eggs; incubation by both sexes.

Movements. While largely sedentary throughout its range, some local dry-season movements, possibly governed by availability of food, have been noted in Sudan, Kenya and Tanzania.

Status and Conservation. Not globally threatened. Generally common in most parts of its range. Locally abundant in S Sudan, over much of Uganda and throughout the L Victoria basin.

Bibliography. Bannerman (1953), Britton (1980a), Buckley *et al.* (1989), Cave & Macdonald (1955), Chapin (1939), Cheesman & Sclater (1935), Dowsett & Forbes-Watson (1993), Friedmann (1930a), Fry *et al.* (1988), Jackson & Sclater (1938), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Praed & Grant (1957, 1970), Nikolaus (1987), Rutgers & Norris (1972), Short *et al.* (1990), Smith (1957), Snow (1978), Urban & Brown (1971), Zimmerman *et al.* (1996).

Class AVES
Order CUCULIFORMES
Suborder CUCULI
Family CUCULIDAE (CUCKOOS)

- Small to medium-sized, slender landbirds, most with fairly narrow bill and long tail; generally dark above and paler below, a few with all-dark plumage.
- 16-70 cm.

- Cosmopolitan.
- Mainly forest and woodland.
- 28 genera, 136 species, 295 taxa.
- 10 species threatened; 1 of these probably extinct since 1600.

Systematics

The 28 genera and 136 species of the Cuculidae are remarkably variable in their social behaviour and parental care, to a degree perhaps unmatched among the world's birds. Because they are so diverse in their breeding behaviour, the systematics of the group are of special interest. Brood parasitism has probably evolved independently at least twice in this family, but the relationships among the major groups are not well known, and estimates of the phylogeny of the cuckoos are needed to infer the conditions for the evolution of brood parasitism.

Certain fossils earlier considered to be of cuckoos were fragments of single bones, several of which have been reidentified as associated with other systematic orders. The oldest fossil of cuckoo resemblance is from the Eocene, at the time of the first appearance of most avian families: a remarkably complete Eocene fossil, *Foro panarium* from Wyoming, USA, has some cuckoo-like characters such as a pectineal process of the pelvis, and is said to represent a primitive group of landbirds; it has other traits resembling those of the turacos (Musophagidae) and the Hoatzin (*Opisthocomus hoazin*, Opisthocomidae). Other questionable records from the Eocene are *Uintornis* from the Middle Eocene of Wyoming and *Parvicuculus minor* from the Lower Eocene of England, which may both be coraciiform birds, and *Dynamospteryx velox* from the Eo-Oligocene of France.

The oldest known fossil cuckoo is *Neococcyx mcorquodalei* from the Lower Oligocene Cypress Hills in Saskatchewan, Canada; it appears to be related to the present-day Coccozinae of the New World. A terrestrial fossil cuckoo, *Cursoricoccyx geraldinae* from the early Miocene of Colorado, was smaller than the modern Lesser Roadrunner (*Geococcyx velox*); it had a less strongly developed coracoid, and tarsometatarsal elements apparently specialized for cursorial life, although the carpometacarpus was relatively longer than on modern terrestrial cuckoos. Fossil roadrunners apparently the same species as the Greater Roadrunner (*Geococcyx californianus*) and a possibly conspecific one known as Conkling's Roadrunner (*Geococcyx conklingi*) are known from the Pleistocene, and persisted well into the Holocene to less than 6000 years ago in arid regions of the south-western USA and Mexico; *G. conklingi* was larger, and may have been adapted to inland temperatures and a continental climate.

Fossil cuckoos are scarce, however, and records in the Northern Hemisphere are nearly all restricted to the Tertiary and Qua-

ternary, while those in the Southern Hemisphere are no older than the late Quaternary. In Madagascar, a fossil coua, *Coua primaeva*, is known from the Quaternary and a giant subfossil coua, *Coua berthae*, which was the size of a small turkey, is known from cave surface deposits. Recent and prehistoric fossils in the Old World include some of the Great Spotted Cuckoo (*Clamator glandarius*) in Israel and the Common Cuckoo (*Cuculus canorus*) in Europe. Those from the New World include Black-billed (*Coccyzus erythrophthalmus*) and Yellow-billed Cuckoos (*Coccyzus americanus*), two squirrel cuckoos (*Piaya*) and one lizard-cuckoo (*Saurothera*), three of these in the Dominican Republic; two anis (*Crotophaga*) in the West Indies and Yucatán; and the American Striped Cuckoo (*Tapera naevia*) in Brazil; as well as roadrunners in the North American south-west.

These known cuckoo fossils are unlikely to be representative of the true historical geographical distribution and morphological diversity of the cuckoos, nor do they reveal anything of when or where brood parasitism originated in this group. They do, however, establish that cuckoos were present in the Oligocene and Miocene in the New World, and that forms similar in their overall morphology occurred at that time, so the groups of cuckoos have a long evolutionary history.

Modern studies of molecular genetics indicate that the cuckoos are not closely related to any other families of birds. In morphology they appear closest to the turacos, and the two families are traditionally combined in the order Cuculiformes. They also appear similar to the doves (Columbidae), and in their leg muscles they bear a resemblance to some parrots (Psittacidae). The DNA-DNA hybridization data of C. G. Sibley and J. E. Ahlquist, however, do not support any of these assumptions of a recent common ancestor, and those authors concluded that the DNA comparisons showed that the cuckoos have no close living relatives.

Interestingly, molecular-genetic studies suggest that the Neotropical Hoatzin may also be a cuckoo (see Volume 3, page 24). The Hoatzin and the cuckoos are more similar to each other in DNA-DNA hybridization scores and in mitochondrial 12S and 16S nucleotide sequences than either is to other birds, and this may be due to their having originated from a common ancestor; indeed, the Hoatzin was included as a New World cuckoo by Sibley and Ahlquist. In the molecular studies, however, the Hoatzin was compared only with cuckoos and with Galliformes, and these two groups do not exhaust the candidate relatives of Hoatzin. Moreover, the DNA-DNA hybridization scores were

Subdivision of the
Cuculidae.

[Figure: Hilary Burn,
Francesc Jutglar, Chris
Rose & Ian Willis]

not well defined, and the defined nucleotide sequences were too short to give any sort of definitive answer in the groups that were tested.

Relationships within the cuckoos have been investigated, and groups of taxa have been recognized on the basis of their anatomy, molecular genetics, distribution and breeding biology. Studies of the bony palate, the postcranial skeleton, the leg muscles, and the geographical distributions of the major groups of cuckoo species show little agreement between sets of data. The cuckoos appear to have speciated independently of their hosts, and there is no suggestion of cospeciation of parasites and hosts which might shed light on the major relationships among the groups of cuckoos. Similarly, the ectoparasites of the cuckoos indicate no close relationship either to other groups of birds or within the cuckoos themselves.

On the basis of their DNA-DNA hybridization data and geographical distributions, cuckoos have been separated into six distinct families: the Old World parasitic cuckoos; the malkohas and couas; the coucals; the American cuckoos; the anis; and the New World ground-cuckoos. Another molecular-genetic test of relationships used the electrophoretic analysis of feather keratins, but the sampling of representative cuckoos was scanty, and not all species that were sampled were compared with each other. The more complete published similarity matrix, when re-analysed with a neighbour-joining programme, indicates that: (1) Old World and New World cuckoos are distinct groups; (2) the Old World parasitic cuckoos are most closely related to the malkohas; (3) this clade is the sister group of the coucals; (4) the New World Coccyzinae are most closely related to the anis; and (5) this clade is most closely related to the roadrunners and the pheasant cuckoos (*Dromococcyx*) in the New World ground-cuckoos. Other studies have used such parameters as nesting habitat and egg colour, but these characters appear to be questionable for the estimation of phylogenetic relationships, and in some cases, such as habitat, the traits do not directly reflect the genetic traits of the birds.

The present work recognizes a single family of cuckoos as set out by J. L. Peters in 1940. It agrees with the conclusions of the DNA-DNA hybridization studies, however, in so far as the Old World cuckoos can be seen to comprise one major group, including the brood parasites, the malkohas, the Asian ground-cuckoos, the couas and the coucals; and the New World species represent another group, although in contrast to the DNA conclusions the Coccyzinae are included with the other New World cuckoos. This arrangement is consistent with the results of a comparative immunological feather study by A. H. Brush and H. H. Witt published in 1983. The Cuculidae is thus divided into six subfamilies: in the Old World are the Cuculinae (Old World brood-parasitic cuckoos), the Phaenicophaeinae (Old World nest-building cuckoos with short, curved wings and long tails, including the malkohas, the Asian ground-cuckoos and the Madagascar ground-cuckoos or couas), and the Centropodinae (coucals); and in the New World are the Coccyzinae (New World arboreal cuckoos and lizard-cuckoos), the Crotophaginae (anis and guiras), and the Neomorphinae (roadrunners, New World ground-cuckoos, and New World brood-parasitic cuckoos). In this working hypothesis, the three Old World groups are in one clade and the three New World groups represent a second clade.

Since the relationships of the cuckoos are not well understood, however, alternative systematic arrangements have also been proposed. There is no common agreement, for example, on whether the ground-cuckoos and the couas of the Old World are more closely related to the malkohas of the Old World, or to the New World ground-cuckoos. Their anatomical similarities with the New World birds are postcranial and may reflect common but independently derived adaptations to terrestrial locomotion. The main basis for recognizing the malkohas and couas as a single group is the similarity of plumage and their occurrence in the Old World. Because they are short-winged birds it is unlikely that they would disperse across the ocean, and that terrestrial cuckoos were derived from a common ancestor that also was terrestrial and had limited ability to make long-distance move-

Although the cuckoos are usually treated as a single family, Cuculidae, some authorities prefer to separate them into as many as six families, basing this treatment at least in part on DNA-DNA hybridization data, as well as geographical distribution. One such family recognized by some scientists is Centropodidae, containing all the Old World coucals, here illustrated by the Coppery-tailed Coucal. The phylogenetic relationships of the various groups, however, remain very unclear, and further comparative studies are clearly needed.

ments. Many authorities prefer to award the couas a subfamily of their own, but for the time being the most appropriate arrangement may be to recognize two tribes, Phaenicophaeini and Couini within this subfamily.

In 1988, in a comparative study of the postcranial skeletons of cuckoos, D. E. Seibel found that there were major differences both within and between the systematic groups that are recognized here, and the implications for the evolution of brood parasitism and the interchange or isolation between Old and New World cuckoos are dramatically different. In the estimate of phylogenetic relationships in the skeletal study, when turacos were taken as the reference outgroup, the cuckoos were inferred to have colonized the New World from the Old World on five occasions, and the Old World and New World parasitic cuckoos were each other's closest relatives (this group included also the New World nesting Yellow-billed and Black-billed Cuckoos), and there would be equally as many independent colonizations of Old and New World if the colonizations were assumed to go in the other direction or if reversals were assumed. This inference is based on the assumption that the skeletal characters are a true guide to the phylogenetic relationships within the cuckoos.

In the analysis based on skeletal characters, the ground-cuckoos of the Old World, including the Madagascar couas, were most closely related to the ground-cuckoos of the New World, and neither group was closely related to the arboreal cuckoos in their respective region. The characters that linked these ground-cuckoos, however, were all features of the synsacrum and tarsometatarsus, and these may have derived their structure independently in relation to the terrestrial mode of locomotion. The only traits that were regarded as shared derived characters linking the coucals, the couas, and the Old World and New World ground-cuckoos were: (1) the relative length of the ilioischial synsacrum (long); and (2) the contour and orientation of the anterior edge of the posterodorsal iliac crest (straight and more laterally directed). The author noted that this first character is problematic within the remaining cuckoos, and most had a form intermediate between the ones described as distinct. Also, within this first set of cuckoos, a second set was comprised by the couas, the Old World ground-cuckoos and the New World ground-cuckoos, which were uniquely linked only by the structure of the proximal end of the coracoid, involving the inflection of the

acrocoracoidal furcular facet; this, however, was an unordered and unpolarized three-state character, so it is difficult to interpret homology, and the author noted that definition of the states for this character is problematic. Third, within this last set of cuckoos, the Old World ground-cuckoos and New World ground-cuckoos, including the roadrunners, were linked only by the relative size and position of a tubercle on the tarsometatarsus, and by the relative position of the distal edge of the proximal foramen of the tarsometatarsus.

Because all these features were on the synsacrum and legs, or were problematic, and since all these cuckoos share a common pattern of cursorial locomotion, such skeletal characters are very likely to be adaptations for running on the ground, and are the kind of characters most likely to have evolved independently in these groups of cuckoos. No characters were described that would link these groups, except for the pelvic locomotor assemblage. Unless future phylogenetic estimates which are based on other kinds of characters such as molecular genetics indicate the same relationships among the groups of ground-living cuckoos in the Old World and the New World, it is therefore questionable whether these common skeletal traits can be attributed to a set of evolutionary synapomorphies among these terrestrial birds in different parts of the world.

On the other hand, only one character was found to link the remaining groups of cuckoos with each other. This was the supposed derived condition of the length of the posterior extent of the medial angle of the posterior dorsal iliac crest, relative to the width of the vertebral centra. The cuckoos that are so united are the New World anis, the New World parasitic cuckoos, New World coccyzine cuckoos such as the Black-billed Cuckoo and the Squirrel Cuckoo (*Piaya cayana*), and Old World malkohas and brood-parasitic cuckoos. The perception of this synsacral character as a derived synapomorphy is probably the result of selecting the turaco as the outgroup, that is, the standard of comparison against which the other characters are thought to be derived. It is uncertain, however, whether turacos are in fact the birds most closely related to the cuckoos. These long-legged birds may well have synsacra that are highly adapted to their own bounding manner of locomotion in trees (see page 488), so it is questionable whether their synsacral traits are good standards of comparison to assume the evolutionary polarity of characters in

The Banded Bay Cuckoo of southern Asia is sometimes placed in a monotypic genus, *Penthoceryx*, while some authorities prefer to include it within a rather broadly defined *Cuculus*.

The majority of taxonomists would, however, seem to agree that the most appropriate treatment is to place it in *Cacomantis*, as it shares a number of morphological traits with the species usually grouped therein. It differs markedly from other adults of this genus in its heavily barred plumage, but this is, in turn, very similar to the immature plumages of the same species.

[*Cacomantis sonneratii schlegeli*, Borneo.

Photo: Roland Seitre/Bios]

the cuckoos. The shape of the iliac crest in this set of cuckoos may be primitive (plesiomorphic) and may not represent a derived character, and there is no corroboration of the hypothesis that these cuckoos represent a monophyletic clade and are each other's closest relatives.

Within this set, a putative clade involving the Old World and New World arboreal cuckoos linked the parasitic cuckoos of both regions plus the Old World malkohas and the New World coccyzine cuckoos. The two characters identified as synapomorphies for this clade were: (1) the contour of the head of the scapula, though this was coded in four different character states (plus another in the Old World ground-cuckoos of the genus *Carpococcyx*, which had a "problematic" form that was "superficially" like that of the malkohas); and (2) the form of the ulna, but this was coded as a six-state character among the cuckoos and so is of questionable utility in this analysis.

Finally, nestled within this last set, another questionable putative clade was based on a single character of unlikely evolutionary status: the New World Black-billed Cuckoo and other *Coccyzus* cuckoos were reported to be the sister group to the Old World brood-parasitic cuckoos, but excluding the Old World koels and the Channel-billed Cuckoo (*Scythrops novaehollandiae*), which formed paraphyletic groups basal to the putative *Coccyzus-Cuculus* clade. The character on which this latter clade was recognized was the occurrence of a sulcus, or groove, in the anterior tibiotarsus, between the mesial foramen and the tubercle for the tibialis anticus and associated structures. In *Coccyzus* the sulcus is shallow and barely visible; whereas in most of the *Cuculus* clade it is deep, apart from in *Clamator*, which is similar to *Coccyzus*, and perhaps in *Pachycoccyx*, which was not examined as no complete skeletons are available in any museums. The difference in sulcus depth suggests that the character is not uniquely derived in this perceived clade, but represents a different origin of the sulcus in *Coccyzus* and in these Old World parasitic cuckoos; the occurrence of *Coccyzus* in this perceived clade appears to be the result of coding the three sulcus states as stages on a single evolutionary transformation, hence of an assumption of homology and not an independent analysis of characters.

The relationships of the couas, the Old World ground-cuckoos, and the malkohas among the Old World cuckoos are equally uncertain. The scheme that is followed here did not include a

molecular-genetic analysis of the couas, the Old World ground-cuckoos or the coucals, though it combined all these into a single putative clade with the Old World brood-parasites, and within this set it separated the coucals as a sister group to the other Old World cuckoos. Furthermore, no direct comparisons were made between the malkohas of the Old World and the arboreal cuckoos of the New World, where one was used as driver and the other as tracer in the DNA-DNA comparisons. Traits that are similar in the Old World ground-cuckoos, the couas and the malkohas are the soft, lax plumage with dove-like colours in some species in each of these groups; the platform nest, unlike the covered nest of the coucals; and their distribution in the Old World. None of these traits is exclusive to these cuckoos among the world's birds.

Recent analyses published by J. M. Hughes in 1996 have also associated the New World *Coccyzus* cuckoos (Black-billed and Yellow-Billed Cuckoos) with the Old World brood-parasitic cuckoos. An analysis based in part on the postcranial skeletal features, but also on egg colour and various aspects of behaviour, suggested that these nesting cuckoos are most closely related to the Old World parasites, and they may even have re-evolved their nesting behaviour from the brood parasites. The conclusion is consistent with the DNA-DNA hybridization data, which cluster the nesting arboreal coccyzine cuckoos of the New World with the Old World brood parasites. This would, however, be the only instance among the world's birds where nesting were lost in one lineage, and the descendants of the lineage then independently evolved nesting and parental care for a second time. The hypothesis should be tested with additional data, including molecular-genetic data.

Further studies of phylogenetic relationships among the cuckoos are clearly needed, and comparisons of their molecular genetics in particular are anticipated.

In defining species limits among cuckoos, voice is considered one of the most important parameters. The standard songs of a species occur over a wide geographical range, this range-wide similarity of voice having been demonstrated for species which are sufficiently well known. We can therefore use song as a major guide to the species themselves: enabling not only the identification of a species of cuckoo in the field, but also the determination of the biological limits of species where the

populations differ in appearance from place to place. If the songs are the same, then the populations are likely to be conspecific; while allowing for call and song repertoires as occur in the Brush Cuckoo (*Cacomantis variolosus*) and the Common Koel (*Eudynamis scolopacea*), if the songs are different, then the populations are likely to represent distinct species. If the populations differ both in morphology and in song, then it is very probable that the cuckoos involved are of distinct species.

Using song as a guide to the species limits of the cuckoos, most authors now recognize the African Cuckoo (*Cuculus gularis*) as a species distinct from the Common Cuckoo. The African birds have a yellow bill, they sing with an emphasis on the second syllable, "cuck-óo", and this syllable rises rather than drops in pitch compared with the first note. The Palearctic birds on the other hand have a black bill and sing with the accent on the first, higher note, producing the "cúck-oo" song that gave rise to the name of the family. The birds respond by approaching a source of their own kind of song but not that of the other type of song, so they behave as distinct species. In addition to their songs, these two cuckoo populations show constant differences in their morphology; in adult and juvenile plumages; and in bill colour and width, wide at the base in the African Cuckoo, and narrow in the Common Cuckoo.

Other species which are now recognized as distinct both in minor morphological traits and in song are the Asian Drongo-cuckoo (*Surniculus lugubris*) and the Philippine Drongo-cuckoo (*Surniculus velutinus*); the Himalayan Cuckoo (*Cuculus saturatus*) and Horsfield's Cuckoo (*Cuculus horsfieldi*); and Hodgson's Hawk-cuckoo (*Cuculus fugax*) and the Philippine Hawk-cuckoo (*Cuculus pectoralis*). The songs of the two drongo-cuckoos differ in the number of notes they contain and in their pitch and rise from note to note. The Asian Drongo-cuckoo's song is usually of six notes sung individually "one, two, three, four, five, six", rising up the scale, whereas Philippine Drongo-cuckoos have 8-10 notes in their song and these are given more rapidly in a series with all the notes closer to one pitch. The adult Asian Drongo-cuckoo has a glossy mantle and the tail is usually forked, whereas the Philippine Drongo-cuckoo has a velvety mantle and the tail is square-ended; the juveniles of these cuckoos also differ in plumage, Asian birds being black with small white spots, and Philippine birds uniformly rufous in colour.

The Himalayan Cuckoo's song is a high note followed by two or three lower notes, "hoop, hoop-hoop" or "tun-tadun"; that of Horsfield's Cuckoo is four low "hoop" notes, the first one soft. The two cuckoos also differ in size, though the largest Himalayan Cuckoos in their breeding range overlap in wing length with the smallest Horsfield's Cuckoos.

Finally, Hodgson's Hawk-cuckoo of Asia calls through the night, a shrill "gee-whizz, gee-whizz", with the first note higher in pitch than the second; the Philippine Hawk-cuckoo gives a series of short crescendo calls that rise and fall in pitch, each phrase of 6-8 notes lasting 1 second, and a prolonged crescendo call that rises and then falls in pitch. In the hand, these cuckoos differ in the shape of the wing, which is more pointed with the outer feathers longer than the inner primaries in Asian birds and more rounded in Philippine birds.

Wing shape is variable within populations of the Common Koel, and additional tape recordings are needed to test whether these may also comprise more than one species, as is frequently claimed.

On the other hand, several forms which replace each other geographically have songs which are apparently identical. This gives a strong indication that the birds would behave towards each other and towards their counterparts with the same songs as if they were of the same species. There are three particularly good examples of geographical populations of cuckoos which have apparently identical songs and therefore appear to be conspecific. The first is the Plaintive Cuckoo (*Cacomantis merulinus*), the grey-breasted Indian race of which is replaced by rusty-breasted races in South-east Asia, Malaysia, Indonesia and the Philippines. Thus, this species is considered to include the form *passerinus*, often reckoned to be a distinct species; this interpretation of conspecificity is consistent with the intermediate plumage of some juveniles in Assam, where the ranges of the two forms meet. In the second case, the northern and southern populations of the Brush Cuckoo combine grey-breasted forms and the rusty-breasted or Indonesian cuckoos of the race *sepulcralis*; the eye-rings of these birds are yellow from South-east Asia through the Philippines to New Guinea and the Solomon Islands, and even in some individuals in Australia, although some field guides state that the eye-ring colours differ between the northern and southern birds. The third major case is that of

Four species of lizard-cuckoo are currently recognized. The Jamaican Lizard-cuckoo is confined to its namesake island, and there are also endemic species on Hispaniola and Puerto Rico. The fourth species is polytypic, and is resident from the Bahamas to Cuba and its islands. In the past, lizard-cuckoos and roadrunners were sometimes lumped generically, largely on account of their somewhat similar dietary habits, but the two groups are now unanimously separated because of their very different morphology and general behaviour.

The problem of cuckoo taxonomy is well illustrated by the Common Koel. Widely distributed from Pakistan and India east to the Philippines and Australia, it is commonly split into three separate species on the basis of bill colour and the plumage of the female. The vocalizations of all forms across the entire range appear, however, to be similar, indicating probable conspecificity. This adult female, photographed in a suburban garden, shows the typical head pattern of the Australian forms.

the Common Koel, which occurs as a polytypic species through southern Asia and Australasia, although the subspecies groups *melanorhyncha* and *cyanocephala* have sometimes been raised to separate species status on the basis of bill colour and female plumage colour. In all of the above cases, part of the problem of comparing songs and species has been that each form has more than one vocalization, and so extensive recordings are required to determine whether the comparable types of calls are the same; for example, the Plaintive Cuckoo has a rising song, a cadence song, and a single whistle.

Finally, the Little Bronze-cuckoo (*Chrysococcyx minutillus*) occurs in many forms from South-east Asia through the Malay Archipelago and the Philippines to New Guinea and northern Australia, and song appears to be a useful guide to assessing whether just one species or as many as four are involved. More field recordings are needed to be certain, but, because the songs appear to be the same throughout this wide range, both the green-backed and rusty-backed forms appear to represent a single species.

The same criteria of vocal identity are applied to the nesting non-parasitic species of cuckoo. The African Black Coucal (*Centropus grillii*) is sometimes considered conspecific with the Lesser Coucal (*Centropus bengalensis*) of Asia and with the Madagascar Coucal (*Centropus toulou*) of Madagascar, but the voices of these cuckoos differ, as do their sizes and the details of their plumage, so all three are here regarded as distinct species. Nevertheless, the species limits of coucals are uncertain in some cases, as the songs do not always differ noticeably between what appear to be distinct species. Moreover, coucals tend to exclude other species from their territories and geographical range even when these are not the most closely related forms.

Morphological Aspects

One of the more distinctive features of the cuckoos is the zygodactyl foot, with the inner and outer toes directed backwards and the other two toes directed forwards. The plumage is soft and lax in most species, the legs are short, and the tail is long, often longer than the rest of the bird. The bill is usually slender, with the upper mandible arched.

All cuckoos are capable of flight, although this varies from the swift and direct flight of the long-winged, long-distance migrants such as the Common and Black-billed Cuckoos of northern temperate zones, to the gliding flight of the short-winged tropical forest-living malkohas, and the awkward slow flight of

the short-winged tropical coucals. Wing shape is conservative within cuckoo species generally. Even the resident or intra-African migrant African Cuckoo has the same pointed wing shape as the Common Cuckoo, the species to which it is most closely related.

Cuckoos are medium-sized birds, having a total length within the range 16–70 cm. They vary in mass from 17 g in the smallest, the Little Bronze-cuckoo, to 550 g in the largest, the Greater Black Coucal (*Centropus menbeki*). Most cuckoos have a slender body form and short tarsi, and are arboreal, while others are more heavy-bodied, have long tarsi and are terrestrial. Other notable features of the cuckoos are: long eyelashes; ten primaries, 9–13 secondaries, ten rectrices (eight in the anis); the eutaxic wing with a secondary feather for each secondary covert; the feather after shafts absent or very small; absence of a cere; scutellate tarsi; and a naked and bi-lobed oil-gland.

The skeleton of cuckoos does not exhibit any traits that are unique among birds, and many features appear to be primitive (plesiomorphic) characters that have been retained from ancestral landbirds. The details of the zygodactyl foot differ from those of other birds with a generally similar toe arrangement, that is the trogons (Trogonidae), the turacos, the parrots, the owls, the Cuckoo-roller (Leptosomidae), and the Piciformes, including the woodpeckers (Picidae). Cuckoos have a desmognathous palate, a small vomer, a holorhinal nasal septum, no basipterygoid processes, 14 cervical vertebrae (13 in the Old World crested cuckoos of the genus *Clamator*), 17–18 presacral thoracic vertebrae, a pectineal or preacetabular process on the synsacrum, and two bony canals in the hypotarsus. Many other morphological aspects of cuckoos are variable within the group and, curiously, are not closely associated with each other, nor do they correspond well with the subfamilies as now recognized. These include: the shape of the sternum, which is notched, windowed or intact; the presence or absence of certain leg muscles; and the form of the syrinx, which can be bronchial, tracheobronchial or intermediate in its position.

Some of their morphological features are associated with the lifestyle of these birds, in particular within the terrestrial cuckoos when compared with the arboreal cuckoos. The pelvic muscles of the roadrunners originate farther forward and to the side than in the arboreal cuckoos, and these may support the stability and balance of a running bird that places its weight alternately on one leg and then on the other. Roadrunners also have elongated leg bones, especially the tarsometatarsus, and the toes are mobile and flexible, allowing the bird to vary the shape of the foot on a flat surface.

Some cuckoo species possess strikingly glossy metallic plumage colours, none more so than the African glossy cuckoos of the genus *Chrysococcyx*. The male Diederik Cuckoo has beautiful iridescent green upperparts with a copper-coloured sheen. This species is one of several cuckoo species which exhibit sexual dimorphism in plumage, the female being much browner above and less white below, and with browner irides.

[*Chrysococcyx caprius*, Wadi Darbat, southern Oman. Photo: Hanne & Jens Eriksen/Aquila]

The plumage of cuckoos is variable in texture, and is usually soft. The delicate feathering tends to become wet in the rain, and cuckoos are often seen sunning themselves to dry after a rain shower. Anis have smooth, dense glossy plumage, and this texture appears to be related to their more frequent habit of seeking food in wet grass and foliage, where their feathers consequently become wet. In cool, wet weather they hang out their wings spread to the sun's rays, like storks or vultures.

Some coucals and malkohas have elaborate feathers on the neck, the hackles, which bear conspicuous stiff feather shafts, the colour of these shafts sometimes contrasting with that of the rest of the feather. The Blue-faced Malkoha (*Phaenicophaeus viridirostris*) of India has unique bifurcate feathers on the chin and breast which are formed by stiff barbs that cling together on each side of the central rachis, which itself protrudes as a fine, free, black hair-like bristle in the centre of the fork. The most bizarre feathers, however, are found in the Scale-feathered Malkoha (*Phaenicophaeus cumingi*) of the Philippines, which has the barbs of each feather of the head and throat united into a single shiny, metallic-looking, flat blue-black shield that contrasts with the otherwise whitish plumage of the head and throat; these iridescent ornaments develop even on the short-tailed juvenile birds. Other malkohas develop their elaborate adult-like plumage early in life, as demonstrated by the other Philippine species, the Rough-crested Malkoha (*Phaenicophaeus superciliosus*), which grows its red bristle-like head feathers while still a short-tailed juvenile.

Most adult cuckoos have a long tail, and this is used both as a rudder in slow flight and also, in the case of the cursorial ground-living cuckoos, as a steering device. The tip of the tail is often contrastingly coloured: the Chestnut-breasted Malkoha (*Phaenicophaeus curvirostris*), for example, has a green tail with a red tip, while many other species of malkoha and, in the New World, coccyzine cuckoos have either a broad or a narrow white tip to the tail.

The plumage is cryptically coloured in many brood-parasitic species, although the males of some glossy cuckoos are bright, and in other glossy cuckoos both the males and the females are brightly coloured. There may therefore be an interesting evolutionary conflict between sexual selection on the one hand and, on the other, ecological crypsis to avoid being detected by the host species. Downy feathers in the cuckoos are limited to the apteria. The greatest difference between adult and juvenile plumages is exhibited by the parasitic species and by the coucals, while some of the latter also have intermediate plumages between the juvenile and the adult stages.

The plumages of several cuckoos may be adaptive to ecological problems of recognition and social associations with their hosts. The juvenile plumage of Common Koels somewhat resembles that of their host species: black like crows (*Corvus*) in India, where the koels parasitize crows; and streaked brown in Australia, where their hosts include Brown Honeyeaters (*Lichmera indistincta*). Some cuckoos of the genus *Cuculus* resemble hawks in their plumage and flight, and in some parts of Europe the geographical variation in the proportion of female Common Cuckoos that are grey or rufous in plumage parallels that of *Accipiter* hawks and *Falco* falcons, although how this resemblance aids the female cuckoo in getting an egg into the nest of her hosts is unknown. The variation in plumage colour may also be density-dependent, such that the rarer form has an advantage in not being recognized by the naive young songbird hosts, while the commoner form is recognized and chased by the nesting hosts. A similar situation exists in some polymorphic falcons, hawks and owls, where the rarer colour morph may have an advantage in not being recognized by its prey.

Sexual dimorphism in plumage colour occurs in a few cuckoos, perhaps more so in the Old World parasitic species than in others. Sexual plumage dimorphism is found in some malkohas, most notably Raffles's Malkoha (*Phoenicophaeus chlorophaeus*), and in the African and Asian glossy cuckoos and the Common Koel. The iris colour, and sometimes its pattern (a ring of colour in the iris), also differ between the sexes in some cuckoos, both in the glossy cuckoos and in several malkohas.

In most species, males and females are usually the same in body size, but occasionally they differ. Males of several brood-parasitic species are slightly larger, by less than 10%, than their females. On the other hand, a number of cuckoos exhibit reversed sexual size dimorphism, the female being the larger of the sexes. Females are larger than males in the brood-parasitic Channel-billed Cuckoo and also in many coucals, one of which is known at times to be polyandrous; the degree of sexual dimorphism is constant across subspecies in some coucals. Females are larger than males also in the co-operatively breeding anis, nesting studies of which have shown the dominant female to leave more offspring than the subordinate females in their communal nest. In another co-operative breeder, the Guira Cuckoo (*Guira guira*), however, females are not larger than males. In the anis and the coucals, the females compete with other females: in the former instance for the position of eggs in the communal nests, and in the African Black Coucal for territories with more than one male to help in parental care. Females of most other coucals are also larger than their males, even among monogamous species such as the Pheasant Coucal (*Centropus phasianinus*), where the fe-

The cuckoos of the New World subfamily Coccyzinae form a group of nest-building cuckoos. Along with their Old World counterparts in the Phaenicophaeinae, they are characterized by a long, graduated tail, this being particularly marked in the aptly named Squirrel Cuckoo. This species inhabits tropical forests, old secondary forests, mangroves and plantations in Central and South America, where it has evolved into 14 subspecies which vary in depth of coloration and also, to some extent, in plumage pattern. In the northernmost part of the range, the two forms occurring in southern Mexico, darker *thermophila* and brighter and paler *mexicana*, appear to show little or none of the intergradation which would be expected of adjacent subspecies, and they may even be two distinct species.

[*Piaya cayana thermophila*,

Photo: Patricio Robles Gil/
Sierra Madre]

male is half as heavy again as the male. In these cuckoos where the female is larger than the male, body size appears to be related to aggressive behaviour, with females taking a majority role in social dominance within the group or in the territorial behaviour of the pair, much as in some hawks, falcons and owls. This contrasts with the situation among some other bird groups, such as the buttonquails (Turnicidae), the tinamous (Tinamidae), the painted-snipes (Rostratulidae), the jacanas (Jacanidae) and certain shorebirds (Scolopacidae), where reversed sexual size dimorphism is associated with a polyandrous mating system. Females of the African Black Coucal, which are larger than males, are, however, sometimes polyandrous.

The greatest degree of size dimorphism occurs in the coucals of smaller body size. This differs from the more standard situation in other families of birds, in which the males are relatively larger than females in the larger species. Nevertheless, size di-

morphism is certainly quite marked in some of the larger coucals too, such as the Greater Black Coucal.

The pattern of wing moult is a shared, derived trait within the Old World parasitic cuckoos. In cuckoos, the feathers are replaced not from the innermost outwards as in most birds, but from separate centres within the wing. Moult proceeds by forward or backward leaps across one or more adjacent primaries. In the Old World parasitic cuckoos, the primaries are shed in a more distinct pattern of saltatory or transilient moult than in other cuckoos. The crested cuckoos are unique in that their wing moult progresses in a regular pattern, with the sequence of primaries 6-9-pause-7-10-pause-8-5 (or -5-8). This moult, together with the plumage and skeletal traits, indicates that these cuckoos are a single derived group. The long-tailed cuckoos (*Cercococcyx*) have a unique moult of first the odd-numbered primaries, then the even-numbered ones. Other cuckoos have yet other patterns of transilient moult of the primaries, with the Common Koel quite different from the other Old World parasitic cuckoos. Moult is a protracted affair, and in the case of the Common Cuckoo takes many months. In some cuckoos it may be delayed for months. In others the moult is interrupted, with birds in their first year not in active moult and with the wings bearing a mixture of juvenile and adult feathers; this is amply demonstrated by the Great Spotted Cuckoo, where these feathers are of noticeably different colours.

Morphological and other features distinguishing the six sub-families are outlined in the following paragraphs.

The Cuculinae are brood-parasitic cuckoos of the Old World. Most are migratory and have long, pointed and narrow wings. The tail is long and often graduated, with the central feathers longer than the others. The legs are short, with the tarsus feathered at the base. Some species resemble hawks in their shape, their brown or grey plumage colour and streaked (juvenile) or barred (adult) pattern, and also their swift and direct flight; several in fact bear the name "hawk-cuckoo". Their hawk-like plumage may elicit mobbing from their hosts, and this may aid the cuckoo in finding the hosts' nests in which to lay eggs. Other parasitic cuckoos are small, and in their general appearance more like passerines. Most Old World brood parasites are dull in plumage, and their cryptic appearance may allow them to avoid detection by their host species. The glossy cuckoos and the bronze-cuckoos, however, can be fairly conspicuous in their

Most cuckoos have a long tail, used both as a rudder in flight and for manoeuvring among foliage and on the ground. The malkohas, which hop along the branches and tangled creepers of tropical forests, make twisting movements with the tail to keep their balance, before turning to seize an insect. The sole African malkoha, the Yellowbill, is a confirmed skulker, like most cuckoos.

[*Ceuthmochares aereus australis*, Malindi, Kenya. Photo: Alan Weaving/Ardea]

Although, in most cuckoo species, the sexes are similar in size, males of some brood-parasites are sometimes slightly bigger than their mates. In a few instances, however, reversed sexual size dimorphism is apparent, the female being the larger of the sexes. This phenomenon is exhibited by many coucals, as well as by the rather strange-looking brood-parasitic Channel-billed Cuckoo of Australia, the largest of all brood-parasitic birds and easily recognized by its huge two-tone bill, which it uses to pluck fruit, particularly figs.

[*Scythrops novaehollandiae*, Australia. Photo: Roland Seitre/Bios]

Totally restricted to Madagascar, where nine species currently survive, with a tenth now almost certainly extinct, the couas are large cuckoos possessing soft, lax plumage of dove-like browns and rufous, except for the blue plumage of the Blue Coua (*Coua caerulea*). They also have long tails and large feet, as well as areas of brightly coloured bare skin around and behind the eye, and often, like the malkohas, they have long eyelashes.

A few couas are arboreal in their habits. The Crested Coua, for example, generally forages at 5 m or more above ground, often in the canopy of the forest; it is locally common, and still hangs on in degraded forests. For the most part, however, the couas are terrestrial, as typified by the Red-capped Coua. This species spends much of its time on the ground, where it walks around among the litter and debris of open forest and other wooded areas in search of food; this is the only terrestrial coua species to be found commonly in degraded wooded habitats. Both these species feed mainly on large insects, supplemented with some fruit, the Crested Coua also taking some snails and chameleons.

A notable feature of some brood-parasitic cuckoos of the genus *Cuculus* is their resemblance to raptors. Not only are they long-winged and long-tailed, but their plumage is also grey or brown and clearly barred, recalling *Accipiter* hawks, and their flight is typically swift and direct. The Common Hawk-cuckoo is one of several species whose vernacular name reflects this similarity. The hawk-like plumage of these cuckoos may elicit mobbing from their hosts, thereby perhaps helping the cuckoo to locate the hosts' nests.

metallic plumage colours, especially male glossy cuckoos of the African species. The nestlings of these brood-parasitic cuckoos are naked at hatching, and the inside of the chick's mouth is brightly coloured but lacks special visual marks.

The subfamily Phaenicophaeinae consists of nest-building, non-parasitic cuckoos of the Old World tropics, mainly in southern Asia. These have strong, unfeathered tarsi, short, rounded wings, and long graduated tails that are tipped with bold spots and bars. This group includes the malkohas, the long-tailed skulking arboreal cuckoos of the forests. Many have brightly coloured unfeathered skin around the eye and face, and the bill is large, arched, and often brightly coloured. The feathers often have wide vanes on the wings and stiff, shiny shafts of a colour that contrasts with the other parts of the feathers. Nestling malkohas have conspicuous palatal spots. The three large ground-cuckoos of the genus *Carpococcyx* inhabiting southern Asia, and also tentatively placed in this group, have long, unfeathered tarsi, but they are similar to the malkohas in the dove-like greens and blues of the plumage, the bright bare skin around the face, and the long eyelashes, and also in their nesting habits. Finally, the couas, the large cuckoos endemic to Madagascar, have soft and lax plumage with colours of dove-like browns and rufous, but blue in the Blue Coua (*Coua caerulea*). They show a long tail and large feet, and colourful bare areas of skin around the eye; like the malkohas, they often have long eyelashes. As a group, the couas are terrestrial, though a few are more arboreal. As with the malkohas, the palate of the nestling coua is conspicuously patterned.

The coucals forming the subfamily Centropodinae are mainly large, skulking, heavy-bodied terrestrial birds with long, stout feet, a long straight claw on the inner hind toe in most species, short rounded wings, and a long broad tail. The plumage is black, rufous-brown or whitish, or a combination of these colours. They live in the Old World tropics from Africa and Asia to Australia, New Guinea and the Solomon Islands, and occur on many isolated islands in the Australasian region, where they have differentiated into several species. They are morphologically the most distinct group of cuckoos. The single genus has 28 recognized species, the largest number of any cuckoo genus, and it contains birds with the largest body size of the cuckoos; all species essentially show variations on a similar body form. The chicks have a strange stiff hair-like down, and conspicuous coloured spots on the palate.

In the New World, the nest-building Coccyzinae are the counterparts of the Old World Phaenicophaeinae and, like the latter, have a long, graduated tail. Most are arboreal in their behaviour, and most are insect-eaters, feeding especially on caterpillars; several are large-bodied cuckoos living only on islands of the

Caribbean, where they feed on lizards. Some species have long wings, and several of these cuckoos are long-distance migrants between continental North and South America, or between breeding areas in southern parts of South America and non-breeding quarters in northern South America. These cuckoos are nest-builders, and the young, where known, have contrasting papillae on the inside of the mouth.

The New World Crotophaginae are nesting, group-living cuckoos characterized by a thick bill, thick legs and a long tail. The three anis species have black plumage, and the South American Guira Cuckoo is streaked brown. The nestlings have pale markings on a pink mouth. Anis often have a strong smell, especially when they are roosting in groups at night, and this may attract blood-sucking bats and predators. Their generic name *Crotophaga* means eater of "croton oil", which is the oil of the East Indian croton tree (*Croton tiglium*) and is a foul-smelling medicinal purgative. The anis are awkward in their movement, with wings and tail seemingly disconnected from the body, and they progress in rapid jerky movements, unlike the smooth moves of arboreal cuckoos in the New World. Anis are slow and clumsy as they flutter and clamber through low bushes and weeds, where their flopping wings and waving tails may flush insects in dense vegetation. The Guira Cuckoo on the other hand is much more graceful, its flight having been described as recalling a kite in the wind.

The final subfamily is the Neomorphinae, the New World ground-cuckoos. These cuckoos are long-legged and long-tailed, and vary in their breeding behaviour. Most are nest-builders, but three are brood parasites. The group includes the lizard-catching roadrunners of semi-arid regions of North and Central America, and the large South American forest-living ground-cuckoos which follow army-ant swarms. At least some nesting species have nestlings with conspicuously coloured mouth spots. The roadrunners can cover considerable distances at speeds of up to 30 km/h when chasing their lizard and grasshopper prey. Running at top speed, a bird holds the head and the tail level with the ground and swings its tail like a rudder; birds often course along roads, paths and dry stream beds. Although the Greater Roadrunner usually walks and runs on its daily routine rounds, it can fly, although even when sitting on an elevated perch it usually stays within a hop and a flap of the ground.

Habitat

Cuckoos are for the most part birds of forest and woodland. The majority of the species are arboreal and feed in trees, many in

evergreen forests in the tropics and subtropics. The forests provide a wide variety of insects, especially caterpillars, which form a substantial part of the diet of these birds (see Food and Feeding). For most bird species, one of the most important considerations is that of finding suitable breeding habitat, but the brood-parasitic cuckoos have dispensed with this complication, so that their only concern in this respect is that of finding the handily situated nest of a potential host species that is ready to be parasitized. This has helped to give many such species fairly catholic tastes in terms of habitat, with the result that it is no real surprise to find them in any sort of landscape, especially if at least a few trees are present.

Within the general theme of forests, cuckoos' habitats can be fairly varied, but for many species the type of forest frequented includes relatively undisturbed primary tropical rain forests, and indeed for several species this is the chief or the only habitat. Other cuckoos occur in secondary forest, and some of these have adapted to living in plantations, particularly of cocoa, stands of which contain larger natural trees as an overstorey layer of shade. "Forest" habitats range from primary evergreen to semi-arid scrub in Madagascar.

While woodland or forested areas represent the main habitat for most cuckoos, some species are more adaptable. In Europe and Asia, for instance, the Common Cuckoo is a good example of a species which occurs in virtually any habitat where suitable host species are present and nesting. In Britain, many Common Cuckoos regularly occur in and around reedbeds, where they parasitize Reed Warblers (*Acrocephalus scirpaceus*), while another very common host is the Meadow Pipit (*Anthus pratensis*), which breeds in very open, often totally treeless habitats such as heaths and moorland. Some cuckoo species have become sufficiently adapted to life alongside man that they can quite frequently be found in city parks and gardens, as is the case of the Common Koel, the Plaintive Cuckoo, the Diederik Cuckoo (*Chrysococcyx caprius*), the Lesser Coucal, the Squirrel Cuckoo and the ubiquitous Common Cuckoo.

A few cuckoos live in coastal mangroves. These include, not surprisingly, the Mangrove Cuckoo (*Coccyzus minor*) in the Neotropics, as well as some malkohas and coucals in southern and South-east Asia and Indonesia. Mangroves are inhabited also by some parasitic cuckoos in Australasia, especially the Little

Bronze-cuckoo, which parasitizes flycatchers of the genus *Gerygone*. Coucals are often found in swampland and marshy habitat, but they also occur commonly in areas of rank grass and in the undergrowth at the forest edge.

Several members of the family live in open brush country in semi-arid regions, such as most of Australia, the plateau country of Africa, Mexico and the drier parts of Central America, and sub-Amazonian South America. In Australia, the Pallid Cuckoo (*Cuculus pallidus*), as well as being present in open forests, woodland and mangroves, occurs in scrub and on thorny plains and even in the arid interior, and it is in fact commonest in drier country. Barren mountain slopes are also occupied by cuckoos, as for example in the Caribbean, where the Hispaniolan Lizard-cuckoo (*Saurothera longirostris*) can be seen in such habitat.

Several cuckoos live in seasonally hot, arid and semi-arid habitats. These include the roadrunners of the New World, some coucals in Madagascar, and several brood parasites in the Old World. While the dry-country brood parasites escape the extreme conditions when they migrate, the others live as permanent residents in the deserts.

The altitudinal range occupied by cuckoos in general is not particularly wide. The majority of species are birds of the lowlands and the lower hills, with relatively few ascending much above 2000 m. Nevertheless, some can be found above 2500 m in several parts of the world. The Jacobin Cuckoo (*Clamator jacobinus*) occurs up to 3000 m in Africa, and even reaches 4200 m on passage in the Himalayas, while the African Emerald Cuckoo (*Chrysococcyx cupreus*) breeds at 3000 m in Ethiopia. In Nepal, the Large Hawk-cuckoo (*Cuculus sparveroides*) breeds to 3000 m, the Indian Cuckoo (*Cuculus micropterus*) occasionally higher, to 3700 m, and the Common Cuckoo to 3800 m; and in China, Horsfield's Cuckoo occurs as high as 4500 m in Sichuan. In the highlands of New Guinea, the Rufous-throated Bronze-cuckoo (*Chrysococcyx ruficollis*) can be found in montane forest at up to 3350 m, although it prefers somewhat lower elevations.

In South America, Yellow-billed Cuckoos are common on passage up to 2800 m in the Andes of Colombia and Ecuador, and migrants occur as high up as 4200 m in Venezuela, though this species breeds at much lower altitudes. Similarly, the Dark-billed Cuckoo (*Coccyzus melacoryphus*) is mainly a lowland breeder, but it reaches 2800 m in semi-arid montane valleys of

Characteristic of many ground-dwelling birds are long, unfeathered legs, as shown by this Coral-billed Ground-cuckoo, the largest of the three Asian *Carpococcyx* species. These Old World ground-cuckoos are similar to the malkohas and the coucals in having short, curved wings and a long tail, and in the soft dove-like colours of their plumage, their bright bare facial skin, and their long eyelashes, and also in some of their nesting habits; the relationships of these three groups, however, remain debatable. The Coral-billed Ground-cuckoo is one of a number of cuckoos considered near-threatened, with a small range limited to Thailand and Indochina.

[*Carpococcyx renauldi*,
Thailand.

Photo: Roland Seitre/Bios]

The Long-billed Cuckoo, a New Guinea endemic, is sufficiently distinct from other cuckoos to be placed in a monotypic genus. It does, however, display the soft plumage colours characteristic of most of the Cuculidae. The immature, shown here, has a dark iris, whereas that of the adult male is red: this is a common age difference among cuckoos in general. As with many New Guinea birds, this is a very poorly known species.

[*Rhamphomantis megarhynchus megarhynchus*, south-east New Guinea. Photo: Brian J. Coates]

Ecuador and in the Peruvian Andes, with several records at 3600 m. Even the Lesser Roadrunner, a species typical of lowland scrub in central America, occasionally ascends to 3000 m.

General Habits

Cuckoos are generally solitary birds, and are more often heard than seen. The calls of some species are among the most characteristic sounds of the forests and woodlands (see Voice), especially in the tropics. As a whole, they are mostly arboreal and spend much of their time in the trees, although the large coucals and couas and some other tropical cuckoos are terrestrial birds. While most species live solitary lives, or live in pairs, and call mainly in the breeding season, others are colonial and interact with each other at all seasons.

Cuckoos are mainly diurnal. Again, however, both the nest-building species and the brood-parasitic cuckoos often call also at night, and in their habits they can be to some extent night birds, along with the owls (Strigiformes) and the nightjars (Caprimulgidae).

Cuckoos live in cold and wet conditions, as well as in more hospitable ones. In the rain their plumage becomes wet, and they often warm and dry their bodies in the sun before they can feed. In fact, many cuckoos are best observed when they sit on a high open perch in the early morning or after a shower of rain, with the wings and tail spread and the back feathers raised to expose the skin to the sun. Sunning behaviour is well known for the coucals and the small glossy parasitic cuckoos of the Old World, and for *Coccyzus* cuckoos, roadrunners and anis in the New World. The couas of Madagascar also sunbathe regularly. The Giant Coua (*Coua gigas*), for example, in the early morning, ruffles its feathers and droops its wings to absorb heat in sunny spots on the forest floor. The Pheasant Coucal is similarly conspicuous in its sunning behaviour.

The anis, especially, seem to get their feathers wet as they forage in wet grass and herbaceous vegetation. They also adapt to cool conditions by lowering their body temperature a few degrees at night in a mild nocturnal torpidity; even when the body temperature drops from 40.8°C to 32.6°C and 34°C after two days of fasting, the birds are still able to fly.

At the opposite extreme, the few cuckoos which live in hot, arid climates are faced with different problems, and it is worth examining some of their responses to these problems. The Greater Roadrunner exhibits a number of adaptations to desert life. These include dorsal skin with melanin, a high body weight, a salt-secreting nasal gland, an ability to reabsorb water through the cloaca, the ability to cool down through evaporation of body water through the skin as the major pathway of water loss, an ability to lower the body temperature at night, and the use of solar radiation as a source of energy. These cuckoos bask in the morning sun by exposing their unfeathered and pigmented black dorsal skin, which absorbs the sun's radiant heat like a solar panel. In winter, in the seasonally cold deserts, they sunbathe in the early morning by spreading their back feathers, drooping their wings and holding them away from the body, and exposing their dorsal skin to the sun. This sunning behaviour reduces the energetic cost of raising their body temperature from its night-time level; the savings can be as much as 60%. Roadrunners also have subcutaneous fat deposits to aid their winter survival; it should be noted, however, that these reserves are not present only during the winter period, since some breeding males also have fat deposits under the skin.

Roadrunners have a metabolic rate similar to that of other birds of the same body size: 0.92 ml oxygen/g-h at air temperatures of 27°–36°C. At temperatures above 36°C their oxygen consumption increases, and at 44.3°C it is 31% above the standard metabolic rate. Roadrunners maintain their basal metabolic rate at air temperatures as low as 9°C when they bask in the sun, but without solar radiation their metabolism begins to rise if the air temperature falls below 27°C, and their oxygen consumption increases with temperatures below this level. By controlling their behaviour, they reduce their food demands: they adopt the habits of their main food, the lizards of the desert, and use the sun when they can. Roadrunners remove excess heat load by evaporative loss of water through the respiratory system and through the skin. During extreme heat, the adults crouch on the ground, spread their wings, and lift the upper set of feathers to allow air to flow between the layers without directly exposing the down feathers to the sun. They also lose heat by fluttering their gular region, panting, and extending their wings to expose the lightly feathered areas underneath the wing, and by a system of heat exchange in the arteries and veins that cool the brain.

The Cuculidae are notable for the zygodactylous arrangement of the toes, the inner and outer ones pointing backwards and the other two forwards. This trait is shared with only a few other bird families, containing almost exclusively arboreal species, but is exhibited by all cuckoos including terrestrial ones. Some of the latter have flexible toes, so that the shape of the foot can be modified on a flat surface. The Lesser Ground-cuckoo hops or walks among leaves on bare ground with jerky, chicken-like movements of its head. It shows the bright bare facial skin that is common among cuckoos, in this case coloured blue, black and yellow.

[*Morococcyx erythropygus*.

Nestling roadrunners, too, are able to warm themselves when they move into a patch of sunlight in the nest. Their skin, apart from that on the chin and the vent, is pigmented black to absorb solar radiation. They are able to cool themselves by fluttering their gular skin and aligning their bodies in the shade of a cholla cactus in which the nest is built. The water lost in gular-fluttering and cutaneous evaporation is balanced by salt secretion of the nasal glands, and by the adult regurgitating a clear liquid (water?) to the nestling roadrunners.

The adults conserve their water by reabsorption through the lining of the rectum, caeca and cloaca, and they excrete salt through the nasal glands in front of the eye, though the salt glands are most prominent in the nestlings. Roadrunners can maintain their body weight without drinking, and they obtain water from food such as reptiles and rodents. Nevertheless, they do drink when water is available, and they have been found drowned in desert pools, indicating that they are attracted to water sources. Breeding adults consume their young nestlings' urine and faeces, which are enclosed in a faecal sac. The nestlings' excreta contain more water than those of the adults, and the adults can satisfy part of their daily water requirements in the course of their normal parental care.

In addition, the adult roadrunners stay inactive in the shade during the hottest period of the day, and hunt mainly during the early morning and late afternoon, when their insect and lizard prey are most active. Roadrunners have a variable clutch size and asynchronous hatching of the eggs, allowing the parents to track changing food resources, although these traits are not unique to cuckoos in desert habitats but occur also in Black-billed and Yellow-billed Cuckoos, which live in less arid habitats.

Adult cuckoos are eaten by larger predators such as raptors and large primates, and their nestlings and eggs are taken by a variety of predators, including birds, mammals and snakes. Both young and adult brood-parasitic cuckoos are eaten by mammal predators, such as vervet monkeys (*Cercopithecus aethiops*) in Africa. Young roadrunners are eaten by dogs, cats and raccoons (*Procyon lotor*), and these sometimes catch the incubating adults on the nest. Anis in Central America are fed upon by large carnivorous bats, and this also suggests that cuckoos are not generally toxic to mammals, as has been supposed on occasion. Cuckoos avoid predators by their stealthy behaviour. Arboreal

species such as the Black-billed and Yellow-billed Cuckoos escape detection by aerial predators through their inconspicuous and watchful behaviour; they are easily overlooked not only by predators, but also by their most visually orientated prey. Other cuckoos take more active measures to avoid predators. Greater Roadrunners, for example, escape capture by an aerial predator by running, dodging, flashing the wings and spreading the tail, and these aspects of their behaviour may distract, confuse or intimidate the predator by making the cuckoo appear larger than it really is. Other roadrunners feign a wing injury near the nest by running from the nest, crouching on the breast, and fluttering the wings.

The nestlings of many cuckoos, in particular the Black-billed and Yellow-billed Cuckoos, the roadrunners and the coucals, excrete a foul-smelling black liquid from the cloaca when they are disturbed on the nest. This is thought to repel many casual predators. These birds are subject to heavy predation, which in the case of roadrunners may be responsible for more than half the nest losses. On the other hand, the young of several brood-parasitic cuckoos appear not to produce the black liquid, but instead they encapsulate their faeces and urine in a gelatinous faecal sac, which is removed by the foster parent. This response, however, changes with the age of the young cuckoo. In the case of the Greater Roadrunner, the young nestlings produce a faecal sac much as do small passerine birds, and the sac is removed and eaten by the parent cuckoos, whereas the older nestlings, when about to leave the nest, produce the foul liquid when disturbed by a nest predator.

Although the nest-building cuckoos take an active role in mobbing predators, and some give a wing-flap distraction display near the nest, the brood-parasitic species appear not to join these mobbing groups. Instead, they leave the defence of the young to the foster parents.

The displays given by male roadrunners towards other males near their territory boundaries differ from the displays directed towards the mate, but do have some elements in common with courtship display (see Breeding). Males call across the territory borders, giving "coo" calls and bowing the head to display the top of the crest and the brightly coloured bare skin behind the eye. If one male intrudes, the territory-owner approaches with the head lowered, the bare skin (particularly the orange skin)

The majority of the members of the Cuculidae live in forest and woodland, a great many species inhabiting tropical and subtropical evergreen forests. Many require relatively undisturbed primary forest, but some survive well in secondary growth or semi-arid scrub, and others have successfully adapted to living in mangroves and cocoa plantations. The Chestnut-bellied Malkoha flourishes in secondary growth, forest edge, mangroves and plantations in South-east Asia, where it lives in the dense crowns of the trees.

[*Phaenicophaeus sumatranus*, Kuala Selangor, Malaysia. Photo: Arnaud B. van den Berg]

fully exposed, and the tail held upright and wagging from side to side. The intruder also exposes his head colours, and the two birds move from side to side until the intruder backs down. The resident may approach in short bursts, running and dodging, and "popping" his wings. The resident female may join in defence by following the male to the territory border and giving "clack" sounds until the intruder has gone.

Voice

The calls uttered by members of this family vary from clear whistles in the case of glossy cuckoos and some of the large *Cuculus* brood-parasitic cuckoos of the Old World, to the harsh screams of the Great Spotted Cuckoo, the coos and rattles of the roadrunners, the hisses and glissandos of the anis, and the guttural sounds of the ground-cuckoos. Coucals give deep sonorous calls, often with a "water-bubbling" pattern which recalls the gurgling sound of water as it rushes from a narrow-necked bottle, with a rising "drip-drip-drip" at the end.

Cuckoos are distinctive in their vocalizations and in most cases are readily identified by their calls. This is especially the case in the Old World, where several species occur which are similar or almost identical in plumage and general appearance. The calls of some species are amongst the most emblematic sounds of their particular environments, as is the case of the Common Koel, the Common and Diederik Cuckoos, and the American Striped Cuckoo.

Cuckoos use their voices to announce their territories and to call to their mates. Most variations of calls are given by males when demonstrating their attendance in the territory. Quiet in the non-breeding season, the cuckoos call repeatedly and often all day long during the breeding season, when their calls are used in their territorial behaviour and in courtship. One call that is associated with courtship behaviour is the "Caterpillar Call" of the male African Diederik Cuckoo: when the male finds a caterpillar, he uses this call to attract a female, before feeding the larva to her. Female cuckoos may also utter a short version of the male's call, as is the case with the New World Yellow-billed Cuckoo, and cuckoos often call back and forth with their mates while they are on the nest. Females of the Old World brood-

parasitic cuckoos of the genus *Cuculus* emit a bubbling or chattering call quite unlike the male's calls; they do not have the loud persistent songs of the males.

The New World ground-cuckoos, including the roadrunners, and the Old World ground-cuckoos also signal with bill-pops, bill-clicks and chatters, particularly in aggressive contexts. Among group-living anis and Guira Cuckoos, communal defence of the territory against other groups involves harsh vocal calls. Guira Cuckoos are said also to imitate the sounds of other bird species, although this has not been shown in experimental studies or with field recordings which could be analysed to compare the similarity of calls of cuckoos and others. Moreover, no cuckoos are known to learn their vocalizations.

Among the cuckoos, vocal repertoires consisting of more than a single song are best known in the Greater Roadrunner. This species has several distinct calls, and these are used in different situations. The most commonly heard call is a "coo". This is a low-pitched hoot like that of a dove or an owl, and is a downward slur, given in a series of about five notes, "coo-coo-coo-coo-coo", by a male as he perches on a post or another elevated site. As the male calls, he lowers his head with the crest erect and the bare skin behind the eye exposed, and moves the bill away from the body with each note. The call is loud and can be heard at a distance of up to 250 m. The second type of call, a short "coo" is given in series of two notes, and is not so loud, being audible to about 30 m; this too is given by the male. The third, a single "coo" is a soft note heard only up to 2 m away and is given by both sexes, during a Flick-bow display in courtship. The fourth, a "bark", is a rapid series of short notes which sound like coyote (*Canis latrans*) yelps; this loud call carries for up to 300 m. It is given by the female, often with the crest raised and the bare skin exposed. Fifth, the "growl-coo", is 3-4 notes of low frequency, given by both sexes. As the bird calls, it distends its throat, fluffs its feathers, raises the crest and usually conceals the bare skin. The sixth, a "whirr", is a soft, low-pitched sound which is regularly interspersed between a series of "put-put" calls, heard up to 2 m away. The male gives the call during a tail-wag display in courtship. Finally, seventh, the "whine" is a single low-pitched call audible up to about 5 m away; it is given by both sexes. The bird shakes its head from side to side as it moves the head downward.

A number of cuckoos, among them the Sirkeer Malkoha of India, may be found in more open habitats. This species inhabits rather sparsely timbered, dry deciduous secondary forest, scrub and bush, usually with a good ground layer of lantana and thick grass. It appears to have a special preference for areas of thorn and grass jungle, and is often found on dry stony hillsides.

[*Phaenicophaeus leschenaultii infuscata*, Bharatpur, Rajasthan, India.

Photo: Roger Tidman/FLPA]

Of these calls, the "coo" series is the one most akin to the long-distance territorial song of songbirds. It is given loudly by the male, from a conspicuous perch, and the male may call for a couple of hours, beginning at sunrise. The male often remains on a single songpost, but sometimes calls from more than one perch site. Finally, males on neighbouring territories alternate their calls during the early morning.

In addition to these vocal sounds, roadrunners rattle their mandibles together in a "clack" while at the same time producing a vocal whine in the syrinx, and the male makes a "pop" by bringing his wings together inwards towards the body. During pair formation, the "coo" and the "bark" are usually given when birds forage apart, and the "growl", "coo" and "whine" when they forage together, as would be expected from the different distances at which these calls are audible in the field. The birds tend to become quiet while they are rearing the nestlings, and become more vocal when they have fledglings.

In the breeding season, many cuckoos call both during the day and at night. These include the nesting species, such as the Black-billed Cuckoo in North America, and several species of brood-parasitic cuckoos in the Old World. In tropical regions, the cuckoos, like doves, often call persistently in the hot middle part of the day, a period when most birds are quiet. They also call particularly when rain is approaching or has just passed, and this behaviour has led to the cuckoos in several continents, including coucals in the Old World, being known as "rain birds". "Brain-fever" cuckoos are named for their persistent calls, this appellation being applied to the Pallid Cuckoo of Australia and to the Plaintive Cuckoo, the Brush Cuckoo and the Large Hawk-cuckoo of Asia. The name "brain-fever" was used for cuckoos in India and Burma because they called all night, and one administrator in Uganda was petitioned to send his collectors to remove these birds as they disturbed the residents' sleep. Some cuckoos, including the Asian hawk-cuckoos and the Plaintive Cuckoo, in fact appear to utter or scream out "brain-fever!" Night sounds are not limited to the brood parasites, but are heard also from the New World nesting species, including the Black-billed and Yellow-billed Cuckoos.

The songs and calls uttered by a species of cuckoo are remarkably similar throughout that species' geographical range. The familiar "cúck-oo" song of the Common Cuckoo, for exam-

ple, is a standard from Britain eastwards through the entire Palearctic to as far as Japan, allowing, of course, for individual birds that sound out of tune near the end of the breeding season, and earlier lore that the songs changed with the season. The African Cuckoo sounds the same over thousands of kilometres, from Gambia and Nigeria through to Zambia and South Africa, as do the Diederik and Klaas's Cuckoos (*Chrysococcyx klaas*) each over its own range through the same region of Africa. All the Shining Bronze-cuckoos (*Chrysococcyx lucidus*) over that species' extensive range from Western Australia through south-eastern Australia to New Zealand are also alike in their whistled songs. These cases indicate that cuckoo songs are determined genetically and develop without the chance of learning any local variations on the species' theme.

That the standard songs of a species occur over a wide geographical range appears to be true for the majority of cuckoos, both the brood-parasitic species and also many nest-building cuckoos. These songs appear to develop innately, and this is suggested by direct observations of the Greater Roadrunner. Hand-reared roadrunners make few calls when young, and the lack of opportunity of hearing their own species' calls does not appear to affect the repertoire of these hand-reared captives, because their adult repertoire appears the same as that of wild adults.

Because a species' songs are so similar across its entire range, as demonstrated by species which are sufficiently well known, song can be utilized as a major guide to the species themselves. It can be used as a tool not only to identify a species of cuckoo in the field, but also to determine the biological limits of species where the populations differ in appearance from place to place (see Systematics).

Food and Feeding

The cuckoos are mainly insectivorous, and are specialists on caterpillars. They feed especially on the noxious, brightly coloured and hairy forms of caterpillar, regularly consuming these and other insects that are noxious to, or are otherwise avoided by, most other insectivorous birds. Yellow-billed Cuckoos, for example, include in their diet gypsy moth (*Lymantria dispar*) caterpillars, tent (*Malacosoma*) caterpillars and *Io* moth larvae. They

Despite their frequently unobtrusive life styles, some cuckoos can at times be conspicuous. This is particularly so when they sing from an exposed perch, a habit frequently indulged in by the otherwise somewhat shy American Striped Cuckoo. This species inhabits scrub, open country with scattered trees and other vegetation, and woodland clearings, and may at times be seen dust-bathing along the sides of roads. Its preference for more open areas has allowed it to expand its range in some parts of Central and South America, where deforestation has created suitable new habitat for this solitary cuckoo.

[*Tapera naevia naevia*, Ecuador.
Photo: W. S. Clark/FLPA]

take these in great numbers, and their stomachs are often packed with a felt lining of caterpillar hairs. Cuckoos also take grasshoppers and locusts, many of which have a distasteful "tobacco" juice, while others have projecting hard legs and shields which the birds remove before swallowing the rest.

As well as being specialists on caterpillars, cuckoos are also generalized predators. Forest cuckoos take large insects such as cicadas and locusts, along with other large arthropods including millipedes, centipedes, spiders, and phalangids, while a few species eat tree-frogs and others take terrestrial snails. The brood-parasitic species not only lay in the nests of their hosts but also prey on the latter's eggs and nestlings. Some other cuckoos are also predators on bird nests; the coucals, in particular, take birds from nests when they find them. A few specialize on lizards, namely the lizard-cuckoos of the genus *Saurothera* that live on islands in the Caribbean where there are few hawks and no lizard-eating hawks. In continental North America, roadrunners take lizards and snakes, as well as mice, small birds and large insects.

There are a few Old World cuckoos that are vegetarians, feeding mainly on fruit. These include three parasitic species, the Dwarf Koel (*Microdynamis parva*), the Common Koel and the Channel-billed Cuckoo, and two couacs; the couacs also take gum exuding from *Acacia* trees. However, no cuckoo appears to depend entirely on fruit, although fruits, especially figs but also berries, tamarinds and oil palm fruits, are the staple fare of the brood-parasitic Common Koel and Channel-billed Cuckoo. These cuckoos, when adults, also include some insects and other animal food in their diet. The young are often fed insects, though nestling Common Koels reared by Figbirds (*Sphecotheres viridis*) receive fruit as well as insects in their diet, and young Channel-billed Cuckoos are fed fruit by the frugivorous Pied Currawong (*Strepera graculina*). Some coucals and the Old World ground-cuckoos, as well as other species, including the roadrunners and the Yellow-billed Cuckoo, also take some fruit. Indeed, Old World ground-cuckoos are sometimes known as "fruit-cuckoos".

Most arboreal cuckoos hunt by ambush, and a bird may remain motionless for many minutes as it peers about from a perch. When it sights a caterpillar on the underside of a leaf or on a tree trunk, it dashes or flies towards it, grabs the insect, and returns to the perch to eat it. This feeding behaviour can be described as a tactic of "peer and pounce". Because caterpillars have guts filled

with indigestible and toxic leaf products, the cuckoos clean the caterpillars before eating them. The cuckoo often bites off the end, wipes the caterpillar back and forth on a branch until the guts are squashed out, or passes it back and forth through the bill to clean the insides, and then swallows the insect. Some hairy caterpillars are beaten repeatedly against a branch, the main purpose of this action being to remove the gut contents, as the caterpillars are often eaten with many hairs intact. The hairs form a felted mat in the stomach of the cuckoo, and are later regurgitated in a pellet.

Cuckoos in North America are particularly attracted to feed on tent caterpillars, which build communal tents of silk. Black-billed and Yellow-billed Cuckoos, along with orioles (Icteridae) and some 60 or more other insectivorous bird species, are drawn to wooded areas where the caterpillar tents hang on hawthorns, wild cherries and other rosaceous trees and shrubs; the tent caterpillars are also major defoliators of aspen, sugar maple, black gum and swamp tupelo and have a significant impact on these trees, which are economically important. Between bouts of foraging the caterpillars remain inside the silk tent, and the layers of silk act like a greenhouse, providing warmth by trapping solar radiation and also preventing convective heat loss from the wind. The tents are important in cool weather, and tent caterpillars are among the earliest of spring-feeding insects, when they forage by following the chemical trails laid down by other caterpillars from the tent to the foraging site, although they also search for food independently; a caterpillar forages from its tent several times a day. Although the tent provides some physical protection, insectivorous birds are able to pierce it and remove the larvae, and they also feed on caterpillars as they move along their foraging tracks. Tent caterpillars are brightly coloured and gregarious, and most caterpillars with these traits are associated with noxious taste and are avoided by many birds. Nevertheless, the cuckoos eat them, and in huge quantities.

Cuckoos often nest in areas that offer an abundant food supply. In eastern North America, this normally involves an abundance of the caterpillar species *Malacosoma americanum* in spring, from May to June, and of another species, *M. disstria*, into autumn; these two common species also overlap in their seasons. Moreover, the clutch size of the Black-billed Cuckoo appears to vary with the abundance of the caterpillars. Tent cat-

While cuckoos in general are solitary birds, their presence often revealed only by their distinctive and characteristic calls emanating from the forest depths, several species are gregarious and colonial and can be seen in groups throughout the year. The latter are typified by the four members of the Crotophaginae of the New World. These are all group-living, nest-building cuckoos which defend their territories communally against other groups of their own species, often with harsh calls. They are highly social birds, as suggested by these Guira Cuckoos and Smooth-billed Anis. They perch and roost in contact, pressed against each other, and, uniquely among cuckoos, they indulge in allopreening.

Guira Cuckoos feed on the ground in flocks of up to 20 individuals, and in the air are elegant and graceful birds. The anis, on the other hand, are awkward and clumsy in their movement, appearing to find flight difficult, and moving with a jerky and fluttering action as they progress through the vegetation. Many cuckoos, but particularly the anis, suffer from plumage-wetting caused by feeding in wet vegetation, in which they use their bill to separate the dense strands as they forage.

Following a bout of feeding, they spread the wings and tail and fluff up their feathers to dry them in the sun. The anis also adapt to cool conditions at night by lowering their body temperature a few degrees in a mild nocturnal torpidity.

Below: *Crotophaga ani*. Photo: F. Koster/ Survival Anglia/ Oxford Scientific Films]

In the cool, damp conditions in which many coucals live, their plumage frequently becomes wet. To counter this, they often warm and dry the body in the sun before feeding. In the early hours of the morning, or immediately after a rain shower, they will sit on a high, open perch, with the back feathers raised to expose the skin, and the wings and tail spread, absorbing heat from the sun in a classic sunning posture. Sunning is very common in some groups including the coucals; indeed, it is at such times that many, such as the Pheasant Coucal, are most easily observed.

[*Centropus phasianinus melanurus*, Kakadu National Park, Northern Territory, Australia. Photo: Peter Cook/Auscape]

erpillars commonly completely defoliate the tree in which they occur, and then move on to another tree. A tree that has been defoliated often has a second or even a third set of leaves in a season, but the growth of the tree is affected by the defoliation. In regions which suffer outbreaks of caterpillars in any one year, these "plagues" typically persist for several years: the mean duration of outbreaks in the northern states is about six years, whereas in southern states the forests are known to be defoliated annually for 20-30 years, and this pattern of abundance may influence the seasonal appearance of the breeding cuckoos.

A single cuckoo has been found to have over 100 tent caterpillars in its stomach, and over a few days one individual can remove hundreds of caterpillars, while cuckoos can eliminate entire colonies of these larvae. Despite this, it is unlikely that cuckoos have a significant effect in controlling the caterpillar numbers. On economically important stands of trees, they are more often controlled by humans through the application of pesticides and by the use of bacteria and viruses as biological control agents.

The malkohas feed by moving through the vines and branches of tropical forests and thickets with hops, balancing by twisting the tail like a squirrel, then turning and seizing an insect spotted on a leaf or axil. The single African species, the Yellowbill (*Ceuthmochares aereus*), is often accompanied by other insectivorous birds and by squirrels; the attendant birds appear to use each other as beaters, a bird grabbing the insects as they are flushed by the mixed flock.

The coucals are generalist predators and take many large insects and small vertebrates, including snakes, lizards, tree-frogs, mice and rats, and small birds. Coucals feed mainly on the ground, often in thick scrub, but also, less commonly, in tangles of vines and on the branches of trees. They are slow and clumsy in their movements, but move rapidly when they locate their prey. When capturing grasshoppers and lizards on the ground, they move forwards with a slow stalking walk, and then, when they are close, they change to a hop and run, and either ambush or chase the prey. Their feeding behaviour is one of "flush and rush". At other times, they tear open bird nests to obtain the eggs and young, and rip bark from trees to reach the lizards and large insects that are concealed behind it. Coucals are recognized as predators by small birds, which mob them. In marsh and swamp habitats they

feed partly in the water, where they take frogs, crabs and aquatic insects, and they occasionally scavenge for dead fish. Those coucals living in seasonally dry habitats are quick to respond when the grasslands are ravaged by fires during the dry season. Like foraging Cattle Egrets (*Bubulcus ibis*), White-browed Coucals (*Centropus superciliosus*) approach the smoke and feed at the edge of the grass fires, taking large insects and small mammals that attempt to escape the flames as the fire advances.

Anis are mainly ground feeders. Groove-billed Anis (*Crotophaga sulcirostris*) and Guira Cuckoos forage most commonly in meadows and pastures in dry open habitats, Smooth-billed Anis (*Crotophaga ani*) also feed in denser herbs in wetter habitats, while Greater Anis (*Crotophaga major*) prefer wet forest edges. The largest bill size is found in the species that live in habitats with larger and wetter leaves; these cuckoos use the bill as a wedge when moving through leaves and when feeding. Dry-country forms take grasshoppers and follow cattle, much as do the icterid cowbirds (*Molothrus*), and, like some cowbirds, the anis may also take ticks from the backs of the cattle, whence their Spanish name, *garrapatero*. Hard-bodied insects are bitten repeatedly before they are swallowed or fed to the young. Members of a social group of anis forage near each other, and, although they may be out of sight in the grass, they stay in contact with much squeaky calling. When a predator comes into view, the anis call and fly up together to higher perches. Their group behaviour is therefore related not only to attraction to an abundant source of food, when birds flush insects which others capture, but also to mutual protection from predators. When feeding in company with a cow or a horse, anis hop along near the front of the mammal and seize the insects stirred up in the grass. As might be expected, they catch more insects per minute when feeding with cattle than when hunting alone, especially in the dry season. Anis also use army-ant swarms as beaters, and catch the roaches and other insects driven from the ground litter by the hunting ants.

As in many other aspects of cuckoo biology, it is the roadrunners that have received the most detailed study, partly because they feed on the ground in open areas and are generally more visible than their arboreal cousins as they stand and scan. The best known cuckoos may be atypical of the family, but their feeding habits are nevertheless fascinating. A bird will move on

Cuckoo vocalizations are highly distinctive, and many species are instantly recognizable by voice. This is particularly important in the Old World, where some species are almost indistinguishable in the field except by their calls, and these vocal differences have been used to define taxonomic boundaries between such species. Cuckoos are generally quiet for most of the year, but call persistently throughout the day during the breeding season in territorial behaviour and in courtship. One of the best known natural sounds in Eurasia is the repeated call of the Common Cuckoo as it announces its territory and calls to its mate.

[*Cuculus canorus canorus*,
Catalunya, Spain.

foot across the desert floor, alternating walking and running with periods of standing and scanning. It may also flush prey as it walks in tall grass, where it finds insects by walking with the head low and brushing the grass; this startles the insects, and when they jump the roadrunner grabs them. In another method used to flush insects from grass, the bird jumps up and flaps its wings slowly over the ground; it then catches the insect on the wing, or watches where it lands and picks it from the vegetation. These terrestrial cuckoos also dart into clumps of vegetation and take large insects such as grasshoppers and crickets, spiders as large as tarantulas, and scorpions, and any small vertebrates they can catch such as small snakes, mice and small birds, as well as the contents of bird nests. They are able to run down lizards in hot pursuit. In addition to running after prey on the ground, roadrunners sometimes leap at flying insects and even flying birds such as swifts (Apodidae) over a dry streambed, and they ambush nectar-feeding hummingbirds (Trochilidae) at their feeding places. They also take young communal bats that fall from the ceiling of a cave or fly into the walls and fall to the ground.

Roadrunners take lizards and snakes in highest numbers in the breeding season. Two birds in a pair may co-operate in attacking a large snake, circling it and alternating their attacks. Beetles and grasshoppers are an important part of their diet in winter, when they seek out insects that are concentrated around the base of rocks; when insects and reptiles are scarce in this cold season, the birds also feed on small birds, fruits and seeds and scattered grain. Roadrunners take fruit such as the sweet seedy fruit of the prickly pear (*Opuntia*) cactus, knocking it to the ground and tumbling it to remove the spiny cover. Fruit can total about 10% of their diet.

By following a hand-reared free-living adult roadrunner, a secondary-school student was able to observe the food items that the bird took on its foraging expeditions through the Texas brush. Its food comprised 263 hopping grasshoppers and 73 flying grasshoppers, 17 scorpions, 28 sowbugs, 7 caterpillars, 3 chrysalids, 14 angleworms, 39 moths, 1 butterfly, 14 centipedes, 2 tarantulas, 16 other spiders, 3 stick insects, 3 small toads, 3 horned lizards, 14 other lizards and a mouse.

Although roadrunners are popularly thought to have a special taste for poisonous snakes, they do not seem to search out rattlesnakes. Nevertheless, when a bird encounters a snake that

is not too long, generally no longer than itself, such as a sidewinder rattlesnake (*Crotalus cerastes*), it may kill and eat it. In attacking the snake, the bird crouches and circles around it, and then darts in to grab the rattlesnake just behind its head with the bill. Holding the head in the bill, the roadrunner whips and pounds the snake against the ground or stones until it no longer moves. Once the victim is dead, it pulls it into the shade of a shrub and eats it.

This behaviour is not reserved for rattlesnakes alone, as roadrunners also toss and batter other snakes and lizards to kill them. When capturing prey, they grasp the victim in the bill and then treat it according to the kind of food it happens to be. Birds are plucked of their feathers, small mammals are killed by a blow to the base of the skull, and larger prey such as lizards, snakes and ground squirrels are held in the bill and then swung and hit again and again against a rock, a stick or the ground. This beating not only kills the prey, but it also separates and crushes the skeleton and thereby reduces it to a narrower form, allowing the bird to swallow its large prey whole; this processing of prey may take up to 15 minutes. Roadrunners kill scorpions by biting at the tail where the poison gland and sting are located; this removes the stinger and prevents the risk of the bird being stung. Roadrunners swallow their prey head first, and in this way avoid the backward-pointing spines and scales of the lizards and snakes.

In the interior of forests in tropical America, the ground-cuckoos follow swarms of army ants, using the ants as beaters to flush insects. The cuckoo appears to wait until an ant swarm enters its territory, whereupon it follows the swarm as it passes through. As the ants move along the forest floor and insects scatter in their advance, the cuckoo waits on the ground or perches on low horizontal branches near the ground. On the ground, it then runs at the edge of the swarm, snaps up an insect or other forest-floor arthropod, and runs away in active bounding movements, changing directions, or it spins away; only occasionally does it flap, to get over a vine or to gain an elevated perch, but extended flight is uncommon. These cuckoos feed separately, usually with only one individual at an ant swarm, and they continue on their separate ways. When they find themselves too close together, however, the cuckoos rush at each other with rapid bill-pops, or they lower the primaries and spread the tail in aggressive behaviour, and then one leaves the swarm. While not in

attendance at an ant swarm, ground-cuckoos wander through the forest, and when they come to an ant trail they appear to recognize it; they follow the trail until it leads to the swarm, and thereby to a source of food. Like roadrunners, the ground-cuckoos, when watched over a lengthy period, become tame enough for an observer to follow them. They are the largest birds in the forest which attend these army-ant swarms, where they appear regularly along with numerous other kinds of birds.

Breeding

Within the Cuculidae there is a remarkable diversity of breeding styles: the variability of the cuckoos in their social behaviour and parental care may be unmatched among the birds of the world. The brood-parasitic cuckoos lay their eggs in the nests of other species and never raise their own young; since two species breed in Europe, where they have been observed for many centuries, their natural history is well known. There is considerable diversity among the brood parasites, with 50 species in the Old World and three others in the New World. On the other hand, four cuckoos in the New World are group-living birds, in which more than one pair or more than one female regularly lay their eggs in a single nest that is attended by several adults; these are the co-operative breeders.

The Old World brood-parasitic cuckoos lay their eggs in the nests of a wide variety of passerine species. Their eggs vary from blue and green to dark chocolate brown to white, and are either spotted or unspotted; many species have more than one form of egg marked by a different colour and pattern. The nestlings are naked when they hatch, though young Shining Bronze-cuckoos in New Zealand have dense down, in contrast to the naked nestlings of the same species in Western Australia. The inside of the mouth lacks special visual marks except for a healthy colour of red, orange or yellow.

Nevertheless, despite the notoriety of the brood parasites, most species of cuckoo live in pairs and regularly raise their own young, while rarely these same species lay their eggs in the nest of a neigh-

bouring pair of their own species or of another species of cuckoo. In addition, while cuckoos do usually breed in pairs, polyandry is also known to occur sometimes in at least one species.

Those cuckoo species that nest show a fair degree of variety in the form of their nests, while the markings inside the mouths of chicks can be of considerable interest. The malkohas build shallow nests in trees, lay chalky white eggs and rear their own young. Their nestlings have conspicuous spots on their mouth palate, and, similarly, the palate of young couas has a conspicuous visual pattern of raised spots that contrasts with the lining of the mouth. The nests of the Asian ground-cuckoos resemble those of the malkohas; in the Coral-billed Ground-cuckoo (*Carpococcyx renauldi*), the only one of these species for which anything approaching adequate data have been collected, the young have white markings on their red palates, and are raised by the adults.

Coucals build large globular or domed nests of grass and leaves with a side entrance. Their nestlings initially have a curious hair-like covering of stiff down, and as the body feathers grow these hair-like structures remain attached to the tips of the growing feathers; they then fall off shortly after the birds fledge. The nestlings also have conspicuous and sometimes species-specific raised and coloured spots on the palate.

The New World Coccyzinae build saucer-shaped nests in trees, and lay either white or blue eggs. The young, where known, have raised papillae on the inside of the mouth, the colour of which contrasts with the colour of the soft palate.

The anis and the Guira Cuckoo often live in aggressive and noisy social groups, in which several pairs defend a common territory and share a communal nest, with two or more females laying their eggs. The nest is flat or a shallow bowl, built in a tree. The mouth of the nestling is pink, with white marks on the roof and around the tongue.

The New World ground-cuckoos vary in their breeding behaviour. Most build a shallow bowl of a nest and rear their own young, but the group includes three brood-parasitic species. At least some nesting species have nestlings with conspicuously coloured spots inside the mouth. The brood-parasitic Pheasant Cuckoo (*Dromococcyx phasianellus*), Pavonine Cuckoo (*Dromococcyx pavoninus*) and American Striped Cuckoo use several species of host, but most typically passerines with covered, domed nests.

All young cuckoos are altricial in their development. They remain in the nest while they grow, they depend on their parents or on other host species to provide food, and they grow rapidly. Nestlings of the species that rear their own young, including the Dwarf Cuckoo (*Coccyzus pumilus*), the Black-billed and Yellow-billed Cuckoos, the Squirrel Cuckoo, and the Smooth-billed and Groove-billed Anis, leave the nest in as little as ten days; they can climb about when they are disturbed, and fledge even before then. The larger species of ground-dwelling cuckoo, including the Coral-billed Ground-cuckoo, the African Black, White-browed and Pheasant Coucals and the Greater Roadrunner, fledge in 17-20 days. In contrast to these species that care for their own young, nestlings of the brood-parasitic cuckoos, such as the Jacobin and Common Cuckoos, Horsfield's Bronze-cuckoo (*Chrysococcyx basalis*), the Shining Cuckoo and the American Striped Cuckoo, take 18-20 days to fledge; the larger Great Spotted Cuckoo takes 22-26 days; and the largest of these species, the Channel-billed Cuckoo, takes 17-24 days to fledge. The nestling period of the brood-parasitic cuckoos is twice as long as that of the nesting cuckoos of the same body size, and the chicks monopolize the parental care of their foster parents for a few more weeks after they fledge.

Most of the nesting cuckoos are socially monogamous, with one male and one female living together in a social pairing, and both sexes raise the young. Even the co-operatively breeding anis appear to maintain distinct social pairs of a single male and a single female. The mating systems of the brood-parasitic cuckoos are not so well known: there appear to be no strong pair-bonds between the sexes in most species, although in some crested cuckoos, especially the Jacobin Cuckoo, the male and female appear to act together, the male drawing the host off the nest while the female slips onto it to lay her egg.

The calls uttered by the Cuculidae vary according to genus. Many species produce clear whistles, some utter harsh screams, while others give coos, rattles, hisses and guttural sounds. Among the most interesting are the deep calls of the coucals, often with a gurgling sound like water being poured from a bottle, with a rising "drip-drip-drip" at the end. Many of the vernacular names given to cuckoos are onomatopoeic, among them the couas, which emit deep cooing sounds. The Giant Coua calls from the ground or low in a tree, giving a deep "wok wok wok...", a guttural "ayoo-ew", short grunts, and a resonant "kookookookoogogo".

[*Coua gigas*, Berenty, Madagascar. Photo: Josep del Hoyo]

A few cuckoos have a polyandrous mating system, in which the female mates with more than one male in a season. In some cases, the male takes a more active and conspicuous role than the female in incubation and care of the young, and on the basis of the roles of the sexes in parental care the coucals are assumed to be polyandrous when a female is able to attract more than one male.

Polyandry is best known in the African Black Coucal, from work carried out in Zimbabwe. One female observed had only one male, but another female had three males and mated with each one in turn, while each male held a separate territory within her large territory. In this latter instance, the males built the nests, the female laid her eggs, and each male then incubated the eggs on the nest in his territory and brooded and fed the young; the female took no active role in the care of the young. Only two females were observed, and only one of them had more than one mate. Additional fieldwork is called for on the mating systems not only of these coucals, but also of other species, especially those with marked sexual size dimorphism in which the female is larger than the male. It must be emphasized that at present the idea that polyandry occurs in coucals is based mainly on indirect deduction from the larger size of the females, but there may be other reasons for their reversed sexual size dimorphism. For example, in many monogamous raptors, including falcons and owls, the females are larger than the males, and the hypotheses to explain this reversed sexual size dimorphism include a specialization by the sexes on different foods in a territory and a social dominance by the female over the male around the nest.

The breeding biology of coucals, for instance the Pheasant Coucal, is atypical of many tropical altricial landbirds. These coucals lay large clutches, they have a short nesting cycle, the nestlings grow rapidly, and the juveniles mature early; actually, these last three traits occur in some other tropical-nesting cuckoos. Their breeding success is high. They add green leaves to the nest before laying, and continue to do so through the incubation period; it has been suggested that these leaves might have some sort of a medicinal effect. Nestling coucals have curious hair-like down which is formed by an elongated keratinized feather sheath. They also have prominent marks and papillae on the palate, and sometimes these are in contrasting colours. The young have a prominent egg-tooth, as in other cuckoos, and they emit a

foul-smelling liquid excretion from the cloaca when they are disturbed in the nest.

The majority of cuckoos living in tropical and subtropical regions breed in the rainy season. In equatorial East Africa, the breeding season coincides with that of local rainfall, where the difference in timing between regions only 200 km apart may be several months. At higher latitudes, in more temperate areas, the cuckoos are seasonal and breed in spring with the rains and warmer weather. The breeding season for the brood-parasitic cuckoos in both areas corresponds with that of their host species, which in turn depend on insect food to rear their young. Nearly all of the nest-building cuckoos also feed mainly on insects, or on other arthropods, or, in the case of the African Yellowbill, on small vertebrates such as tree-frogs, and their breeding is determined by the period when their food is abundant. The North American Black-billed and Yellow-billed Cuckoos have particularly long seasons, beginning at the same time as the earliest-nesting insect-eating songbirds, in April and May, but continuing into August and early September in areas where insects are abundant, in particular in areas with outbreaks of tent caterpillars, which feed in huge numbers on many wild trees and shrubs (see Food and Feeding).

For Greater Roadrunners, the breeding season varies regionally, depending on seasonal temperature and rainfall. In southern California, it breeds from late February at low elevations of the Lower Sonoran Life Zone, and a month later in upland deserts of the Upper Sonoran Life Zone. The fact that both parents contribute in the nesting tasks allows them to raise more than one brood in quick succession. A pair of roadrunners in California can make a second nesting attempt a month after the first, when the male takes over the care of the fledglings while the female lays a second clutch of eggs. In southern Arizona, breeding tends to be bimodal, with nests from mid-April to mid-June and from late July to mid-September, with a pause in the hot dry summer and increased nesting activity after summer rains; breeding peaks may vary with the rains of the year. In Texas the roadrunners breed from March to October, and in Oklahoma they breed from April to July or August.

Breeding displays are known for only a few species of cuckoo. The features shown by two of these may be instructive for the general patterns of display behaviour in the group as a

Although they do take a reasonable variety of other foods, cuckoos, such as this Shining Bronze-cuckoo, are mainly insectivores, specialized on caterpillars. They have a predilection for brightly coloured, hairy types of caterpillar, which, being noxious, are avoided by most other insect-eating birds. The cuckoo peers around for a likely insect, then dashes towards it and makes a quick grab, before returning to its perch. Before swallowing the caterpillar, the cuckoo usually beats it against a branch or passes it several times between its mandibles to remove the gut contents.

[*Chrysococcyx lucidus*

Auscape]

In addition to the many caterpillars in their diet, cuckoos also take numerous grasshoppers and crickets. Many of these insects have a bitter, tobacco-like taste, and others possess a hard protective shield or hard projecting legs which the cuckoo removes before consumption. Unlike most arboreal cuckoos, which remain motionless while scanning for prey, malkohas, like this male Chestnut-breasted Malkoha, will hop through the branches and tangles of their tropical-forest habitats and seize any suitable insect which they come across.

[*Phaenicophaeus curvirostris singularis*, Taman Negara National Park, Malaysia. Photo: Chew Yen Fook]

whole, even though it is difficult to judge just what extent of extrapolation is reasonable. The two best known species are the Greater Roadrunner of North America and the Common Cuckoo of the Palearctic.

In Greater Roadrunners, the male and the female spend time foraging together and calling back and forth before they show an apparent sexual interest in each other. Early in courtship, one bird runs after the other along the ground, often for several hours, the two frequently stopping and resting between chases. The chasing bird runs and lunges at the one in front with its wings and tail raised and fanned, while both birds give "clack" calls. The male intermittently utters a "coo" call from an elevated perch. One bird carries a stick in its bill and presents this to its mate; both sexes take part in this activity, picking up sticks and passing them to the mate or dropping the stick at the mate's feet. This behaviour appears to precede nest-building and may provide a bird with an assessment of the potential breeding performance of its partner.

Before they copulate, the roadrunners perform a "Prance Display". The male approaches the female on the ground in short, quick bursts of speed, holds a food offering in his bill, and wags his tail back and forth. He runs to and from his mate with his wings and tail lifted, then he lowers the wings and brings them inward with a "pop". During this display, he holds his tail over his body and then gradually lowers it; he exposes the postorbital bare skin, erects the crest, and sleeks the contour feathers. The display involves four or five cycles of wing-lifting, and altogether the behaviour lasts for more than two minutes. In a "Tail-wag Display", the male wags his tail from side to side, while he bows and then slowly lifts his head, as he faces the female and gives a "whirr" call. After this, he jumps into the air and leaps over the female or mounts her from the rear. He holds the food in his bill and presents it to the female as the two copulate. The male then dismounts, and the two walk away from each other, flicking their tails. The female eats the offered food, or feeds it to her young if the copulation occurs after the young have hatched: roadrunners copulate socially, and not only for the purposes of fertilization.

In the Common Cuckoo, either sex may begin the active courtship. The female gives a bubbling call and the male approaches; or the female approaches a calling male. The male

then bobs his head, or bows his body, holding the wings open and drooped and the tail raised and fanned; in the fan posture, the male may rotate his body slowly and sway from side to side. The female looks on. The male may on rare occasions present a caterpillar to the female. When mating, the male follows the female silently, and may present a piece of vegetation to her. The female opens her wings slightly, moves her tail to one side, and calls just before mating; the male mounts her, then droops his wings slightly and moves the unfanned tail slowly from side to side. Copulation occurs 1-1½ days before laying the egg, which is fertilized by this mating; it does not take place again until the egg has been laid.

Cuckoos of several species have been seen to spread and raise the tail in sexual display, fragments of this behaviour having been recorded for Old World parasitic cuckoos, the American Striped Cuckoo, the anis and the Guira Cuckoo. The bold patterns of white spots on the tail are presumably important in breeding displays of many other cuckoos which exhibit these plumage traits, such as the malkohas and the New World coccyzines.

Males sometimes feed their mates at the time when the females ovulate and copulate, and they give calls which attract the females. Mate-feeding has been seen in a few brood-parasitic cuckoos, including the Jacobin Cuckoo and several glossy cuckoos: the male catches a caterpillar, calls, and attracts a female, to which he then passes the prey. In the brood-parasitic Diederik Cuckoo, the male has a special place in his territory where he calls with a caterpillar in his bill, and attracts a series of females. When he has a caterpillar, he gives a call. The female gives another call when she attracts the male to feed her, this being especially evident in the African glossy cuckoos such as the Diederik Cuckoo, where the female "Caterpillar Call", transcribed as "deah-deah-deah...", reveals the presence of the courtship-feeding pair. Females which accept this transfer of a caterpillar are often in the act of releasing the ovarian follicle into the oviduct, and this is the time when copulation may be most effective in bringing about fertilization.

The phenomenon of brood parasitism, often associated with cuckoos in the minds of many, is of particular interest. The brood-parasitic cuckoos lay their eggs in the nests of other species, their hosts. The individuals that rear the young cuckoos are the foster

Roadrunners are essentially ground-foraging cuckoos.

They take a wide variety of prey types, both invertebrate and vertebrate, and ranging from very small to quite sizeable items. In winter, beetles and grasshoppers form a major component of their diet but, if insects and reptiles are scarce, they also eat small birds, fruits and seeds, including the sweet seedy fruit of the prickly pear cactus; fruit can even constitute as much as 10% of their winter diet. Reptiles are consumed in greater numbers during the breeding season.

Despite popular belief, roadrunners do not appear to have any special preference for poisonous snakes, although, as this photograph demonstrates, they will certainly kill and consume any rattlesnakes which they come across.

In attacking a snake or large lizard, the Greater Roadrunner crouches and circles around it, darts in and grabs the victim behind the head with its bill, and then batters it against a hard surface until it ceases to struggle. This beating and battering process, which may last for up to 15 minutes, has the additional advantage that it crushes the prey's skeleton and reduces it to a narrower shape, making it easier to swallow whole. A pair of roadrunners may join forces to attack a large snake, circling it and alternating their attacks. These terrestrial cuckoos are able to outrun large lizards, which can form a significant proportion of their diet.

parents. These fosterers incubate the cuckoo egg along with their own clutch, and when the cuckoo egg hatches they feed the young cuckoo. This leads to the loss of their own offspring, when the nestling cuckoo removes the host's eggs or nestlings.

The hosts respond to cuckoos near their nest by mobbing them, flying at them from above, hitting them and calling loudly; other species often react by joining in the mobbing. Mobbing may drive the cuckoo from the nest, and a host may thus avoid being parasitized. When a cuckoo is not near the nest, however, the mobbing behaviour of a host could help it to locate the nest. The host therefore usually restricts its mobbing to the immediate area of the nest when the cuckoo has presumably already spotted this.

A female cuckoo finds the nest of a host by watching the nest-building birds inconspicuously from a concealed perch, and by searching through the habitat of the host species. The cuckoo visits the nest, often while the nest-owner is away feeding, and lays her egg into it. With the best of timing, she deposits her egg during the laying period of the fosterer, when the latter has laid at least one egg, but before incubation has begun. Laying of the egg takes place rapidly, and has been timed at 10 seconds or less. The cuckoo then flies away from the nest, often taking an egg of the host in her bill. Sometimes she removes an egg and flies away with it, consuming it later; at other times she perches on the nest rim and swallows egg after egg. Some nests are preyed on by a female cuckoo which does not return to lay her own egg. Removal and eating of the host's eggs provides the female cuckoo with nourishment, and with minerals to help her form her own eggs later. At nests where the birds have been watched and photographed, only female cuckoos remove the eggs; males, having no need to form eggs, do not. Removing the egg also controls the total number of eggs in the nest, and this behaviour may increase the chance that the fosterer will not desert and will successfully incubate the parasitized clutch.

Occasionally, a cuckoo may remove one of the host's young from the nest, and either eat it or drop it nearby. In much the same way as when a cuckoo takes the entire clutch and the host deserts, this removal of the chick may result in the host pair nesting again, perhaps to be parasitized by the cuckoo.

The female glides from a perch to the nest-site of the host, and lays while crouched in the nest, or on the rim, or perched

above it. In nests that are enclosed or situated in a hole, the female may extrude her abdomen into the cavity and lay without completely entering the nest. It was reported in earlier years that a female cuckoo may lay her own egg elsewhere and then carry it to the host's nest in her bill, but film recordings demonstrate that the female lays in the normal manner at the nest; observations of cuckoos carrying an egg in the bill almost certainly relate to their removing an egg from the nest of a host. In 1924, a committee of field workers in Britain was appointed to solve the argument, and the lack of any reports of cuckoos depositing their eggs away from nests, together with the films available showing a normal laying procedure, indicate that in all probability cuckoos generally lay directly into the nest.

A day or two after it hatches, the nestling cuckoo moves its body under the other eggs in the nest, or under the chicks if the host's eggs have already hatched, and then pushes them from the nest. This "eviction" behaviour is known for about half of the species of parasitic cuckoo, and it has been observed in most detail in the Common Cuckoo. Because the cuckoo chick usually hatches first and removes the eggs of the host, the foster parents do not raise any of their own young from a successfully parasitized nest, but give all their parental care to the young cuckoo and rear their "changeling" as their own. Most cuckoos parasitize host species that are smaller than themselves, and the young cuckoo grows rapidly and takes all the food that would normally have been delivered to a full brood of the host's young.

The young of a few cuckoo species, such as the Common Koel, tolerate the eggs and chicks of the host, but this behaviour is unusual among cuckoos. The tolerance of these nestling cuckoos may in part be forced on them by the larger size of the host species, and is perhaps also favoured because a greater quantity of food is brought in by the larger adults intended for their larger chicks. Young Great Spotted Cuckoos in the nests of crows and Black-billed Magpies (*Pica pica*) often grow up together with their foster nest-mates, while young Great Spotted Cuckoos in the nests of smaller starlings grow at the expense of the host's young and evict them or take all the food, while their nest-mates starve.

The nestling cuckoo evicts the nest contents either within a few hours of hatching, or when it is two days old and strong enough to lift the eggs or chicks and push them from the nest.

While many cuckoos eat hairless caterpillars and a variety of other soft-bodied insects, as well as items such as fruit, they are justifiably famed for consuming vast numbers of noxious hairy caterpillars. Such cuckoos tend to be very active feeders, moving about restlessly in the canopy and also, as with the Plaintive Cuckoo, foraging in scrub and brush in search of tasty morsels. The Plaintive Cuckoo is one of a number of Old World species whose loud, almost screaming calls, heard mostly in the mornings and evenings, sound like the words "brain-fever!". It also has a softer, more plaintive piping whistle.

Coucals are food generalists, their predatory habits often eliciting mobbing from other birds. They are often present around wetlands, where they readily catch aquatic insects, frogs and crabs and prowl the waterside in search of any food. Somewhat surprisingly for cuckoos, they will at times even scavenge dead fish, as demonstrated by this Greater Coucal.

The behaviour varies with the depth of the nest cup of the host. In Australia, Horsfield's Bronze-cuckoo and the Shining Bronze-cuckoo often parasitize host species which fashion a deep cup in a covered or domed nest, and the nestling cuckoos do not begin the eviction until the second morning after they hatch. When the foster parent leaves the nest for its first feed in the early morning, the inactive nestling cuckoo becomes cool. This causes it to become more active, and it pushes itself around the nest until it comes into contact with the contents of the nest, either the host's egg or, if this has hatched, its nestling. It proceeds to lift the victim onto its back, balances its body by using a tripod of its wings and head braced against the floor of the nest, and shoves the egg up until it clears the side entrance of the nest. The foster parent, on returning, ignores the egg near the edge of the nest or fallen into the supporting bush, and it broods the cuckoo, which then becomes warm and less active. Sometimes the nestling cuckoo evicts an egg while the foster parent is actually on the nest, and the latter looks on without interfering as the cuckoo pushes the egg out from under its body and out of the nest.

Although the cuckoo nestling may destroy the eggs and nestlings of the host and cause it to fail to produce any offspring of its own, the host parents often do not discriminate against the cuckoo egg; they tolerate it, and incubate it along with their own clutch. This lack of response by the host to the egg of the cuckoo may have two different explanations. First, the hosts may lack the genetic variation that would allow evolutionary selection to favour their action against the cuckoos. Second, the hosts and their cuckoo parasites may exist in a state of equilibrium, where the gains of rejection are balanced by the costs of rejection (see below) of the parasite. A dynamic equilibrium between host and brood parasite appears to be important in the accounting of adaptations of host and parasitic cuckoo.

Many host species can recognize the eggs of a cuckoo as different from their own, and they remove or "reject" the cuckoo egg from their nest if it does not resemble their own eggs. Cuckoos, in turn, often have eggs that closely match the host's eggs in colour and pattern, and these matching or mimetic eggs are more likely to be accepted by the host and incubated along with its own eggs. Fine tuning of cuckoo egg to host egg by natural selection, however, leads to specialization: eggs that closely match those of one species of host are unlike those of another species of host in the same area. The result of this is a co-evolutionary "arms race". The host develops an ability to discriminate among eggs, and also perhaps a high degree of individual variability in its eggs, so that it can recognize the egg of another bird and reject it (this may also occur with intraspecific brood parasitism); and the cuckoo develops an egg that resembles or mimics the eggs of the host, a heritable variation within a species which a mother cuckoo can pass on to a daughter cuckoo. The nature of the inheritance of egg colour is unknown. It has been suggested

that the genetic traits for egg colour and pattern are located on the unpaired chromosome that is found only in the female (in cuckoos, as in other birds, the female is the heterogametic sex), and this maternal determination of egg colour may prevent a mismatch if a female were fertilized by a male with genes of another egg colour. Unfortunately, however, there are no observations on the genetics of egg-colour polymorphism among the cuckoos.

Eggs of parasitic cuckoos have a hard and thick shell that resists cracking when the female lays her egg from a perch above the nest, and it also resists removal by the host. The egg is laid after the embryo has developed for a day in the oviduct, and the developing egg in the host's nest is tolerant of cooling, as the embryo remains alive for a day after the clutch has been experimentally removed from the nest.

The eggs of the parasitic cuckoos are small in relation to the body size of the adult female, and are often closer in size to the eggs of the host. In contrast, the eggs of the nest-building cuckoos are not small for the size of the adult bird when compared with the situation among other types of bird, and the eggs of the co-operatively breeding anis are relatively large. The small egg size may allow a female parasitic cuckoo to lay more eggs in a season, for reasons of economy, and evidently these may also go undetected in the nest of the host if they resemble the host's eggs in size, as well as in colour and pattern. It also seems likely that this mechanism of the small egg relative to female body size may effectively shorten the period of incubation that the egg needs; without this reduction the cuckoo chick would presumably hatch several days later than the host's own chicks, which could clearly put the cuckoo's entire strategy at great risk.

A female cuckoo usually lays one egg per nest in the nests of a single species of host, often one with eggs that resemble her own. In the case of the Common Cuckoo, each female specializes on a certain species of host, and she tends to exclude other females from her laying area, although two or more types of cuckoo egg sometimes appear within an area. The young cuckoo may imprint on its foster species, and later, as an adult, return to the same habitat and find the most suitable host nests by matching the calls of its own foster parents to the calls of birds in its breeding area.

It has been suggested that a population of cuckoos consists of distinct biological "races" or "gentes" which are closely associated with their foster species. These might involve egg morphs, where a female returns to lay her eggs in nests of the same kind of host that raised her, or they might involve cryptic populations, where both males and females seek out each other. So far, nobody has been able successfully to observe an individual cuckoo from the nestling stage to a later year to determine whether a female, in an area where two or more hosts are equally numerous, seeks out as a target for parasitism the host species that raised

In a number of brood-parasitic cuckoos, including the Great Spotted Cuckoo and other members of the genus *Clamator*, the male, having attracted a mate by calling, will then offer her a caterpillar. This mate-feeding is not infrequently followed by copulation. For a number of species, it has been shown that females which accept this offering are often in the process of ovulating, and this is precisely the time when copulation is most likely to lead to successful fertilization.

[*Clamator glandarius*.

her, which would provide a test of the discrimination and choice of the female cuckoo. It is also unknown whether females are more likely to mate with males with the same foster history as their own. Nor have genetic studies shown differences between cuckoos which were fostered by different host species or which hatched from different colour morphs of eggs. The songs of all male cuckoos in an area appear to be rather similar, and the variation in pitch and modulation between the song given by a male when he is alone and that given when another male enters his area is greater than the variation in song among individual males. So far as is currently known, therefore, it appears that the "races" which live together in an area relate only to the females' egg colours and patterns, and do not involve the separation of exclusive breeding groups within a species of cuckoo.

Most small songbirds in Europe reject the eggs of other birds from their nest, and this appears to be an adaptation to avoid being parasitized by the Common Cuckoo. In field experiments with 34 species of songbird, an egg unlike their own (a model "cuckoo" egg) was placed in the nest: eight species rejected the odd egg on over 80% of occasions; 16 species rejected it in 20-80% of cases; and ten species rejected the strange egg in 0% to less than 20% of tests. Five of the ten species which accepted a strange egg were hole-nesting songbirds which are not parasitized by cuckoos in natural conditions, and one was a cardueline finch; such finches, because they feed seeds to their young, are not natural foster species, and young cuckoos usually do not survive on a seed diet. Acceptance or rejection of an egg is also influenced by the time when the egg is laid in the nest. Birds more often reject the egg when it appears during the period while they are laying than when it appears after they have begun to incubate their clutch.

Although some songbirds reject cuckoo eggs, others are more tolerant and accept them into their clutch, even when they do not closely match their own eggs. It seems likely that the various colours and patterns of cuckoo eggs have evolved together with the responses of certain host species that are intolerant, and that cuckoos laying these mimetic egg forms have later successfully parasitized other species that are not so discriminating. In Europe, several songbirds are parasitized by Common Cuckoos laying blue eggs, but of these hosts the Common Redstart (*Phoenicurus phoenicurus*) and the Whinchat (*Saxicola rubetra*)

are the most discriminating; the other host species, such as the Northern Wheatear (*Oenanthe oenanthe*) and the Pied Flycatcher (*Ficedula hypoleuca*), may then have been parasitized secondarily by these egg-colour lineages of cuckoos, but they do not discriminate so intensively.

In Europe, most small songbirds respond to the threat of parasitism by removing the egg of the cuckoo. In contrast, most small passerines in North America accept the eggs of the parasitic Brown-headed Cowbird (*Molothrus ater*), a member of the Icteridae. Presumably, the difference in reactions is due to the fact that the young cuckoo, when it hatches, kills the host's potential offspring by evicting its eggs before they hatch or by evicting its nestlings, whereas the cowbirds often grow up together with the nestlings of the host, although they may compete for parental care, and the fledging success of parasitized broods is less than that of unparasitized ones.

Removal of a cuckoo egg also has its costs, and this may explain some of the variation among birds in accepting an alien egg in their clutch. When a cuckoo egg is laid late or when it is sterile, there is no advantage to the host in removing it, and the same hosts that remove a cuckoo egg when it is laid along with their own clutch will also accept a cuckoo egg when it is laid well after incubation has begun. On the other hand, when the host removes an egg, it risks damaging its own eggs by spilling yolk on to them, or by dropping the cuckoo egg on to its own eggs and cracking them, or it risks removing its own egg in error. These costs would be similar for both cuckoo hosts and cowbird hosts, so the differences that remain in their behaviour point to the greater impact of the cuckoo egg after it hatches, and the greater gain in reproductive success for the host that removes the alien egg. Together, the effect of a particular cuckoo species on a host, the probability of being parasitized, and the probability of a recognition error in rejecting its own egg are likely to determine whether or not a host ejects a cuckoo egg.

In European songbirds, the variation in colour and pattern of eggs among clutches is greater in parasitized host species than in unparasitized songbirds. At the same time, the variation among eggs within a clutch is lower in these parasitized species. These interspecific differences were predicted from the theory of the co-evolutionary arms race between cuckoo and host. Presumably, there has been selection within host species for birds to

In the Greater Roadrunner, copulation is preceded by a most elaborate prancing display. The male, with food in his bill and with wings and tail raised, makes repeated dashing runs at the female; throughout this display, his crest is raised and the bare postorbital skin is exposed. This preamble can last for over two minutes, following which the male faces his mate, wags his tail from side to side and bows, then gives a "whirr" call before leaping in the air and mounting the female. As the two copulate, he finally presents the food offering to the female.

evolve eggs which they can recognize and thereby to avoid being parasitized by cuckoos. Another possibility is that the variation among eggs of the females of host species is an evolutionary response to within-species brood parasitism: in several species, a female may lay her eggs in the nest of another of her own species, and females which lay eggs of a rare colour or pattern are more likely to recognize an egg of a stranger when it appears in their nest. Among those species that often lay their eggs in the nests of neighbours, however, some of the latter do not reject the egg that is unlike their own. For example, Barn Swallows (*Hirundo rustica*) lay in each other's nests but do not reject the egg of another bird; this species therefore exhibits intraspecific brood parasitism, but it is not parasitized by the Common Cuckoo. The comparison suggests that the variation in behaviour among the songbird species in accepting or rejecting an alien egg is due to their past brood parasitism by cuckoos, rather than to their brood parasitism by conspecifics.

Their immediate behavioural experience with cuckoos may also affect the reactions of the hosts. Experiments have shown that nesting birds are more likely to remove an alien egg from their nest if they have seen a model of a cuckoo near their nest. They are also more likely to remove such an egg if they nest during the breeding season of the cuckoo in spring, rather than after the migratory cuckoos have departed in summer.

The choice of host species by cuckoos is probably determined not only by their individual experience in searching out the species that reared them, but also, in the long run, by the host's population level and its diet. A species which is common makes a better host than one which is rare, as a female cuckoo could find more nests and leave more young; and insect-eaters provide better food for young cuckoos. Where the adult cuckoos have a choice of parasitizing pairs or larger co-operative groups, they do not appear to seek out those birds with helpers that could raise the young, either within a host species or among species which vary in their group size.

The young cuckoos are raised in their nests by their foster parents, which show no apparent discrimination against these "changelings" which replace their own young as the focus for their parental care. Considering that the young cuckoos look unlike their own young, it is amazing that the foster parents rear the stranger. Evidently, they will feed virtually any small bird in

their nest, where the young will indeed usually be their own. There may be some advantage to caring for a chick even in the rare instance when it is not their own, because of the potential cost of discriminating and refusing to feed the parasite. The reasons for this can be explained in the following way. A brood-parasitic nestling cuckoo often hatches before the host's own nestlings, so the first young that a foster parent sees in its nest may be the parasite. If the parent began to care for the first young in its nest, learned the appearance of those young, and rejected later young that had a different appearance, then it would often reject its own young in a later nesting. Learning its own nestlings' appearance may thus be disadvantageous to a host that is parasitized, because a host that "imprinted" on the first young to hatch in its nest, a cuckoo, would reject its own chicks in later nestings as the price of developing the ability to discriminate between its own and other offspring by learning. In this way, the prior hatching of the cuckoo nestling may constrain the evolutionary response of the host.

In the brood-parasitic American cowbirds, unlike most parasitic cuckoos, the nestling parasite does not evict the host's chicks, and a foster parent can therefore see two kinds of young together in the nest. The acceptance and parental care given in the early stages may lead to an attachment of the foster adult to its brood, whether or not one of its own chicks is in the nest, so that learning may constrain the adult to continue to feed the young parasite. There is some evidence for this development of behaviour, in this case involving Great Spotted Cuckoos and their Black-billed Magpie hosts. Adult Black-billed Magpies which have already cared for a young cuckoo in their brood are more likely to accept another cuckoo placed experimentally in the nest than are those that have not previously reared a cuckoo. Although the chicks of both species are reared together, the Black-billed Magpie hosts apparently learn to discriminate as the nestlings grow older, and they increasingly feed their own young in preference to the young parasite, at least when the latter is placed outside the nest; they also tolerate alien Black-billed Magpie nestlings more often than they tolerate cuckoo nestlings, both in and outside the nest.

The young parasitic cuckoo continues to gape after it is fed, and cuckoos that do not evict their nest-mates may compete with them to the point that the foster siblings do not get enough food.

An extremely wide range of host species has been recorded as having been parasitized by one species or another of cuckoo. In the forests of eastern Asia, Horsfield's Cuckoo frequently selects the nests of *Phylloscopus* warblers in which to lay its eggs, in this case that of a Pale-legged Leaf-warbler (*Phylloscopus tenellipes*). Most cuckoos parasitize host species that are much smaller than themselves; the cuckoo chick receives all the food that would normally have been delivered to a full brood of young, and grows rapidly.

Photo: Yuri Shibnev/
Planet Earth]

Unlike the nesting cuckoos, the chicks of which often excrete a foul-smelling liquid, the young nestlings of the parasitic cuckoos deposit their excreta in a gelatinous skin, in the same way as do passerine birds; the package is then carried away by their foster parents. This may be an evolved adaptation to gain continued parental care from the foster parents.

Although the parasitic cuckoos do not raise their own young, the adult males occasionally feed fledged young cuckoos of their own species, either a lone, calling fledgling or one calling while its foster parents are feeding it. This behaviour appears to be misdirected courtship feeding by the cuckoo. These males, usually of the crested cuckoos, or the glossy cuckoos and bronze-cuckoos, belong to the species which also feed caterpillars to their females, and they feed the young as if they were potential mates. Adult parasitic cuckoos do not feed young cuckoos which are still in the nest.

Successful brood parasitism depends on the cuckoos choosing not only a host that will accept their eggs and young, but also one that will bring the appropriate food to the nestlings. Cuckoos, being insectivorous themselves, generally parasitize species which provide insects for their young. The insect diet allows the young cuckoo to grow in the nest and to develop. A few species of cuckoo, however, are able to parasitize hosts that supply other kinds of food to their young. The African Emerald Cuckoo exploits mostly insectivorous hosts, but it also parasitizes the Yellow-whiskered Greenbul (*Andropadus latirostris*), which raises the young cuckoo on fruit. The Diederik Cuckoo parasitizes some weavers (*Ploceidae*) and bishops (*Euplectes*) which feed their young on a diet of seeds, although they also bring some insects to the young.

Because young cuckoo fledglings are loud and persistent in their begging, not only do they attract their own foster parents that reared them, but they may also attract adults of other bird species, and these sometimes feed the fledged cuckoo. As many as four different species of bird have been seen to feed a fledged Pallid Cuckoo, although only one host reared it. This attractiveness of a young cuckoo to other birds, perhaps failed breeders that have recently lost their own young, means that not all observations of fledged cuckoos being fed by an adult bird are good indicators that the feeder in question was also the foster species.

In Africa, the marsh-nesting colonial Red Bishop (*Euplectes orix*) is often parasitized by Diederik Cuckoos which lay

unspotted blue eggs similar to its own in the closed nest. In experiments, the bishops also usually accept model eggs which differ in colour or which are patterned, but not eggs that are very dark or very heavily marked. Presumably because they may reject their own eggs by mistake in the closed nest, these hosts appear to be constrained in their defence by the costs of rejection. The cuckoos, however, are unable to take full advantage of the limited discrimination of their hosts, because, in the large colonies where these birds habitually nest, the numbers of bishops that defend the area are usually sufficient to drive off the cuckoo and prevent it from laying. The rates of cuckoo parasitism are therefore smaller in the larger colonies. The cuckoos may have the advantage in the balance between costs and benefits only in the smaller colonies that are not so intensively defended.

In many tropical areas, the identification of cuckoo eggs is a problem to ornithologists as well as to the nesting hosts. In India, where several cuckoo species occur and may overlap in their exploiting of host species, it is not known for certain which eggs belong to which species of cuckoo. Some of the egg identifications of the influential ornithologist E. C. Stuart Baker, published in the earlier part of the twentieth century, have been called into question. Baker described many eggs that were found in the oviducts of female cuckoos, so the identification in these cases is assured. Cuckoo eggs found in nests, however, are sometimes of questionable origin, since different species may lay similar eggs. The identification of a cuckoo egg should be determined by measuring and photographing the egg, and then leaving it in the nest to hatch and develop into a recognizable young cuckoo. Alternatively, a young cuckoo from a known egg could be reared by hand and examined as it grew, as has been done in Japan. A broad conclusion that can be drawn from this and other cases is that much fieldwork is still needed to determine the details of the life histories of the tropical brood-parasitic cuckoos.

Co-operative breeding is a feature of cuckoos belonging to the subfamily *Crotophaginae*. These species usually live in groups, and more than one female lays in the nest. Guira Cuckoos breed together, with a communal nest, yet there is much conflict and competition among the breeding adults. Guiras are the most markedly group-living species among the cuckoos. Not only do they feed in groups, but they also almost always nest together, and several females lay in a single nest, which contains as many

The most widely studied cuckoo in the Old World is the Common Cuckoo, the most notorious nest parasite of all birds.

The female cuckoo, having located a suitable host nest by watching the nest-building birds from a concealed perch, later visits the nest while the rightful owners are absent and deposits her egg in it.

This is timed to coincide with the host species' laying period, and at a stage when the host has already laid one or more eggs but has not started to incubate. The cuckoo generally removes a host egg, later consuming it, or sometimes even eating several eggs on the spot.

The removal of a single egg ensures that the total number of eggs in the nest remains the same, which may reduce the risk of the host deserting; consuming the egg provides the female cuckoo with minerals to help her form further eggs of her own.

The cuckoo chick, a day or two after hatching, evicts other eggs or chicks, by manoeuvring its body under them and then pushing them over the side; such behaviour is known for about half of the species of parasitic cuckoo. In such instances the young cuckoo then has no competition from any nest-mates, and is normally reared successfully by its fosterers, which, by contrast, are unable to raise any young of their own. One of the most frequent hosts of the Common Cuckoo is the European Reed Warbler (*Acrocephalus scirpaceus*), as in these two photographs.

Once they have left the nest, the young of brood-parasitic cuckoos continue to beg loudly and incessantly for food. They receive regular and frequent feeds from their foster parents, but their persistent calling also attracts adults of other bird species, and these are not uncommonly stimulated to feed the fledgling cuckoo. Although the Red-chested Cuckoo does parasitize the nests of Cape Wagtails (*Motacilla capensis*), the fact that an adult of the latter is observed feeding a young cuckoo does not in itself constitute definite proof that the wagtail actually reared this cuckoo.

as 20 eggs. These are blue-green and, when fresh, have chalky splotches that might allow each female to recognize her own eggs and give them special care. Adult Guira Cuckoos perch on the nest, remove an egg and drop it on the ground, and they also bury other eggs in the nest. In a population of this species in Brazil, 32% of all eggs laid were lost or disappeared: of these, 76% were found on the ground below the nest, where they had been tossed by other adult Guiras, presumably members of the group, during laying and incubation. Chicks are sometimes removed by the infanticidal adults, and the young may kill other nestlings. In a molecular-genetic study that compared the DNA fingerprints of young with those of the attendant adults, the nest-mate chicks were offspring of different adults. In addition, the chicks were usually half-siblings but not full siblings, indicating that the adults were not sexually monogamous in mating. Together, at least two females accounted for more than half the young in a nest; in other words, a single female was not responsible for most of the young raised in a nest, although a dominant female may leave more than her share of the offspring.

Although all the adults attended the nest and cared for the young, no more young fledged in the communal nests of the larger groups than in the other groups, and the number of young fledged per adult did not differ among the small, medium and large groups. Furthermore, the probability of at least one young fledging did not vary with group size. More eggs were laid in groups containing more adult cuckoos, but the number of eggs that were lost was also greater. An adult "sentinel" remains in attendance at the nest while the other group members forage away from the nest, and the attendant is thought to alert the group to any predator threat. When a threat approaches, the attendant gives loud staccato calls, and the other group members then converge on the nest to defend it.

Both the Guira Cuckoo and the anis are highly social. They perch in contact, pressed against each other, they roost in contact, and they preen each other; this allopreening is known among cuckoos only for these group-living species. The Guira Cuckoo's ectoparasites, and particularly its mallophagan feather lice, are common both on the birds themselves and in their nests, and these appear to determine the nesting behaviour of the cuckoos. When Guira Cuckoos breed for a second time in a season, most groups move to a different tree for the second nest. This change

of nest-site may decrease the effects of nest infestation by parasitic insects, or reduce the risk of nest detection by predators.

Groove-billed Anis of tropical America also breed in groups or in pairs in open habitats, such as pastures with scattered trees. Their breeding biology has been observed more closely than that of any other cuckoo in which birds were individually recognizable. Most breeding groups contain two or three pairs of anis, although some have an odd number of adults. Within the social group, each female has a mate with which she spends much of her time in a monogamous social bond. Females lay their eggs in a single communal nest. All members of a social group use the entire territory in the breeding season, although in the dry season the birds move from their territory into areas of other groups, or abandon their territories and move to the edge of a forest. The individual anis which live in social groups containing more adults show higher survival in the breeding season, but they do not produce a higher average number of fledged young; the larger groups produce more fledglings, but not in proportion to the number of females in the group. Certain females are much more successful than others. The eggs of the early-laying females are tossed from the nest by the later-laying female, the bird that is socially dominant in the breeding group. Males incubate at night and females in the daytime; although the males that mate with the dominant females may leave more young, since their mates remove the competition from the nest, these males are more likely to be taken by a predator, when exposed on the nest at night, so there is a risk in mating with the dominant female. Brooding females are occasionally fed on the nest by another conspecific. This behaviour is commoner in the Smooth-billed Ani. Juvenile anis sometimes feed the younger nestlings of the second brood.

After they fledge and are independent, the young anis usually disappear from their group and move out of the area. A few remain, however, either as non-breeders or to become breeders in the group in which they were reared. They succeed in becoming breeders when another bird in the group disappears, or when they enlarge the size of the group; research has shown that all these non-dispersing breeding birds are males. Observations of individually marked birds indicate that the breeding adults in a social group generally are not closely related to each other. This is because siblings tend not to move together when they disperse, most birds do not breed in the group in which they were

Not all young parasitic cuckoos evict their host's eggs and young: the Great Spotted Cuckoo is one of several species that tolerate the host's young.

This species often parasitizes Black-billed Magpie (*Pica pica*) nests, the chicks of both species being reared together; as the chicks grow, however, the magpies apparently learn to discriminate, and increasingly feed their own young in preference to the parasite. If the magpie's eggs fail to hatch, as in the case seen here, the young cuckoo prospers. A cuckoo that hatches in the nest of a smaller starling may evict the host's young, or take all the food while the latter starve.

Gordon]

hatched, and males but not females show some tendency to breed in their natal group.

As already stated, however, the majority of cuckoo species are neither brood parasites nor co-operative breeders. They breed as single nesting pairs. In this respect, the breeding behaviour of the Greater Roadrunner has been particularly well studied. The male roadrunner frequently brings food in the form of mice, small birds, snakes and lizards to his female before mating, and also feeds her during copulation. Partners copulate at the place where they will build the nest, and continue to do so by the nest even after their clutch is complete. Copulation appears to have a social function in bonding the pair together, as well as a fertilizing function when the female is still ovulating. The nest-site is usually in an isolated thicket of small trees, such as mesquite, and bushes, in an area near open ground or short grass, where the birds display and forage. The nest is built 1-3 m above the ground, occasionally higher, in the crotch of a tree or resting along a horizontal branch, usually well concealed and near the centre of the bush or tree. Roadrunner nests can be located by watching and following an adult roadrunner as it runs over the ground with a snake or lizard held in its bill. The bird makes a beeline for the nest shrub, and then hops up to the nest by the lower stems of the shrub. Nests are constructed mainly by the female. The male brings building material in the form of thorny twigs and branches to the site, and gives them to the female when she gives a "whine" call; she incorporates them into the nest. She lays the larger sticks around the edge and the thinner sticks near the centre of the nest, probably to cushion the eggs and nestlings. The pair may begin several nests and desert a site after building for only a few minutes. At the site selected for the final nest, the female builds the platform and then adds a lining of finer material such as leaves, grass, mesquite pods, snakeskin, and dry flakes of cattle and horse dung, as well as feathers. The stick nest is a flattened cup that averages about 30 cm in outer diameter, with an inside depth of 5-10 cm and an outside depth of 15-20 cm. Some pairs continue to build their nest during the incubation period, and the height of the nest may increase as the nestlings hatch and grow and require a larger and more protected living space.

Roadrunners lay a variably-sized clutch of smooth white eggs, usually 3-6 and sometimes as many as nine. Sets of 12-13 eggs

are occasionally seen, but these are perhaps the result of more than one female laying in the same nest. Nevertheless, an individual female can vary the number of eggs she lays; the range of a single female can be 2-6 eggs, and the clutch is often larger after good summer rains and when food is abundant. The eggs are laid usually on alternate days, but also at irregular intervals ranging from one day to four or even nine days, and the birds begin to incubate before the complete clutch has been laid. The eggs are covered continuously, the incubating parent remaining on the nest until its mate arrives to relieve it. The first eggs hatch in about 18 days, but, since some eggs are laid after incubation has begun, the young birds hatch asynchronously on a staggered schedule on different days; the young in the brood are therefore of different sizes, and the age difference between largest and smaller siblings may be as great as seven days. When the chick hatches, the female parent carries the eggshell from the nest, where she breaks and eats it. Last-laid, unhatched eggs are often abandoned in the nest after the first-hatched young have fledged, and the last young roadrunner may remain in the nest a week after the other nestlings have fledged. Success of the mixed-size brood is thought to vary with feeding conditions: all young may be fed if food is abundant, but the adults eat their own young nestlings when food is short.

The young roadrunners remain in their nest while both parents bring food. Both also brood the young, nearly continuously for the first four days and at cool periods later. The adults deliver such food items as lizards and snakes intact to their young; the only treatment they give is to beat the vertebrate prey into a flexible form, while in the case of grasshoppers they remove the hind legs. The adult eats the faecal sac as soon as the nestling defecates. Adults may eat their own young nestlings when the latter are unresponsive or weak, or they may feed these young to the larger and stronger nestlings when food is short. Nestlings may evict their younger siblings from the nest, behaviour reminiscent of the brood-parasitic cuckoos. Nestling roadrunners give a loud vocal "churr"; when disturbed, they rattle the bill and excrete a blackish foul-smelling liquid not unlike that of disturbed snakes.

When the young are somewhat grown, the parents give a series of soft "coo" calls to entice them to leave the nest. They fledge in 17-19 days, or as late as 25 days, or they leave earlier if

they are disturbed in the nest. Roadrunner young at fledging are often only 50% of the average adult weight, and they have been observed foraging with their parents when 70% of the adult size. The adults lead their young farther from the nest during the course of a few days after they have fledged. The fledglings follow their parents on the trail to their feeding areas, where they continue to be fed, quivering their wings as they beg for food, until they can feed themselves competently. Independence from the parents gradually develops about 30-40 days after the young have left the nest. Although the young develop the orange postorbital skin and the grey legs at 14 days and 11 days respectively, while still in the nest, the mouth becomes marked with black only at 50-55 days of age and is not fully black until 80-85 days.

The female Greater Roadrunner sometimes lays a second clutch while her fledglings are still begging from the male, and this complementary biparental care allows the pair to hatch and raise two broods, with the second nesting attempt beginning a month after the first. In Texas, a pair has been seen to have three nests in succession, the first in April, the second in June and the third in August, all of them successfully fledging young. Another pair nested again in July, while still feeding the fledglings from their earlier nest. Some second broods are raised in the same nest as the first, but in other cases a new nest is built.

The complementary parental behaviour of male and female roadrunners in nesting has been studied in California, using radio-telemetry. The males incubate at night, but the partners take turns incubating during the day, with the female spending two long spells on the nest. Males maintain their night-time body temperature at nearly the same as the daytime level. In contrast, the females, which incubate in the daytime only, and also the non-incubating males, lower their body temperature by 5°-8°C at night. Birds that drop their body temperature can save about 36% of their energy requirements during this period. Breeding males are generally in more robust condition, as they have fat deposits under their skin and, at an average of 354 g, they are heavier than non-breeding males, which average 314 g, whereas breeding females have to recover their pre-breeding weight during the period when the male undertakes the night shift. Laying females average 318 g in body weight, but during early incubation they average 290 g; females have regained their former condition by the nestling period, when they average 325 g. Males are in good

condition at the onset of incubation, while post-laying females have depleted their energy reserves. Females therefore stand to gain from nocturnal hypothermia, when they can use their food to regain their body condition rather than maintaining a high metabolic rate, and males are better able to undertake the apparently expensive nocturnal incubation.

Roadrunners may be typical of nesting cuckoos in the major features of their nesting, although most cuckoo species have not been observed in detail. One of the features that may be widespread among nesting cuckoos is that both the male and the female incubate, feed the young in the nest, and tend the fledglings. In the case of the Black-billed Cuckoo, the members of a pair alternate their attendance on the nest during incubation, with each member remaining motionless on the nest for nearly two hours. The female incubates at night, and the male takes over at the time of the first feed in the morning. In most species of coucal, both parents care for the young, although males may take a greater part than females. Also, the passing of food between mates appears to be widespread in the nest-building cuckoos; at least a few coucals, as well as the Black-billed Cuckoo, pass food from one mate to the other in a courtship-feeding display. This transfer of food from male to female before or during the laying period may provide the female with extra nutrients for the formation of eggs, and this extra food may in fact ensure that she has enough food to develop the eggs. In addition, the behaviour may be useful to a female nesting cuckoo before she mates with a male, by providing her with a clue to assess the future performance of the male as a provider of parental care to the young.

Movements

In tropical and subtropical areas, cuckoos arrive at their breeding grounds early in the rainy season and breed at the time when the host species begin to nest. Cuckoos are often called "rain-birds" because their conspicuous arrival and songs coincide with the season of rains. The migrations of the brood-parasitic cuckoos which move long distances between their breeding and non-breeding areas are timed to coincide not only with the season when their hosts breed, but also with the emergence and abun-

Most cuckoos are neither parasites nor co-operative breeders, but live in pairs and build their own nests. All coucals, like this Senegal Coucal, are nest-builders. Unlike the platform nests of other nest-building cuckoos, however, that of coucals is a large spherical or domed construction of grass and leaves, with a side entrance; the adults add green leaves to the nest before laying and throughout incubation. Coucals have a short nesting cycle, but they lay large clutches and generally experience high breeding success. Chick growth is rapid, and juveniles reach maturity early.

[*Centropus senegalensis senegalensis*, near Monrovia, Liberia. Photo: Michael Gore]

dance of caterpillars, which are predictable with the onset of warmer weather in spring in the high latitudes.

Cuckoos which breed in the higher latitudes are known, from their seasonal occurrence in the breeding region, to winter in distant regions. Some species have remarkable long-distance migrations between their temperate breeding grounds in the northern continents and their wintering grounds, which are invariably at least partly south of the equator. Two species that breed in North America, the Black-billed and Yellow-billed Cuckoos, migrate into South America and winter south of the equator, while the Pearly-breasted (*Coccyzus euleri*) and Dark-billed Cuckoos undertake comparable movements between their breeding areas in southern South America and their wintering grounds north of the equator in South America. Two other American cuckoos are apparently at least partly migratory: northern populations of the Mangrove Cuckoo are seasonal in appearance in Florida and the Bahamas; while Ash-coloured Cuckoos (*Coccyzus cinereus*), which breed in central and southern-central parts of South America, are known to move across high mountain ranges in northern parts of South America, at any rate on occasions.

Five cuckoos in the northern parts of the Old World complete long-distance migrations, with at least some of their populations moving seasonally across the equator. These are the Great Spotted, Common, Himalayan, Horsfield's and the Asian Lesser Cuckoos (*Cuculus poliocephalus*). European Great Spotted and Common Cuckoos migrate to Africa, flying non-stop over the Mediterranean and the Sahara Desert, a distance of more than 3000 km. Other cuckoos migrate from continental Asia as far as the Philippines and Indonesia, as is the case with the Asian hawk-cuckoos and the Asian Drongo-cuckoo; or they migrate long distances from Asia and over the Indian Ocean to Africa, as do Indian populations of the Jacobin Cuckoo, some Common Cuckoos and the Asian Lesser Cuckoo. Some cuckoos appear during the migration season on islands in the Indian Ocean, between their breeding and wintering grounds, and those which turn up on the coast in Kenya have flown over 3000 km between India and their wintering area. Madagascar Lesser Cuckoos (*Cuculus rochii*) migrate from their breeding grounds to "winter" in continental Africa.

Certain species regularly migrate within Africa, moving from their breeding grounds in South Africa to equatorial and even northern sub-Saharan parts of West Africa; these include the black morph of the Jacobin Cuckoo and also the Black Cuckoo (*Cuculus clamosus*). Other cuckoos move with the seasons of rainfall in West Africa, where they are found near the more humid coast in the dry season which is shorter there than inland, and then occur farther northwards in the drier, more seasonal savanna of the Sahel during the rains. Among these are the Jacobin, Levaillant's (*Clamator levaillantii*), the Black, the African Emerald, Klaas's and the Diederik Cuckoos and the African Black Coucal, although some of these may also remain as residents in the more coastal areas throughout the year.

In the Australo-Pacific region, certain cuckoos migrate from their southern breeding grounds in temperate regions of Australia and New Zealand to winter in the tropics, sometimes north of the equator. Such movements are undertaken by Horsfield's Bronze-cuckoo, the Shining Bronze-cuckoo, the Channel-billed Cuckoo and the Long-tailed Koel (*Eudynamis taitensis*).

Migrating cuckoos are often very fat, and their stores of fat may persist into the period spent on their non-breeding grounds. This was demonstrated by one Common Cuckoo from the Palearctic which was caught in South Africa in December.

The long-distance migrants occasionally appear on the wrong side of the ocean following disorientation. North American Black-billed and Yellow-billed Cuckoos appear as accidentals on the North Atlantic islands and in northern Europe, the former having been recorded as far east as Italy and the latter as far east as Sicily. Conversely, from the Palearctic, Common Cuckoos turn up in northern North America, both in Alaska and on the Atlantic coast, and Horsfield's Cuckoos occasionally appear in Alaska.

The migration behaviour of cuckoos has been studied in most detail for the Black-billed and Yellow-billed Cuckoos. These cuckoos move at night, and they orientate by the pattern of the stars, as has been shown in planetarium experiments. In autumn,

they undertake an over-water flight of 2000-3000 km from their breeding grounds in North America to the West Indies, whence they continue onwards to South America as far as northern Argentina, or they fly directly as much as 4000 km from North America to the mainland of South America. Yellow-billed Cuckoos appear on migration in places where they do not breed, turning up on islands off the coast of Florida each month from May to August. Their appearance at these places in these months suggests that spring migration may continue as late as June, and that the return to the south may begin by July, although, as these cuckoos may breed in eastern North America as late as August, the later individuals on these islands may be dispersing rather than migrating. Cuckoos also appear as casualties below television towers, the lights of which attract nocturnal migrants, which crash into the towers; the dead or stunned birds thus provide a sample of nocturnal movements. At the television towers, as on isolated islands, the cuckoos appear throughout June and July. Other Black-billed and Yellow-billed Cuckoos migrate overland, where they are seen in Panama from September to November, and again in April, but not during the northern winter, when they are generally observed only in South America. Like juveniles of other nocturnal migrants, the young cuckoos, without any previous experience, are nevertheless able to find their way to their wintering grounds. This is demonstrated by the fact that hand-raised cuckoos become active at the appropriate time of the migration season, and orientate their nocturnal restlessness in accordance with the pattern of the starry sky.

Other migratory cuckoo species may have similar behaviour. Young brood-parasitic cuckoos have no opportunity to learn their migration routes from their parents, as the adults leave their northern breeding grounds several weeks before the juveniles depart from their natal areas. Adult Great Spotted and Common Cuckoos, for example, appear in Africa in late summer, several weeks before the arrival of the first juveniles in autumn. Both breeding species of cuckoo in New Zealand, the Shining Bronze-cuckoo and the Long-tailed Koel, are nocturnal migrants which winter on remote islands in the Pacific Ocean, more than 1000 km from their breeding range. On the other hand, the large Channel-billed

The typical nest of *Coccyzus* and some other nest-building cuckoos is a shallow cup of sticks. In the Black-billed Cuckoo, incubation and brood-feeding duties are shared by the male and the female, a set-up which probably applies to many other nest-building cuckoo species. The sexes incubate in turns during the daytime, each bird sitting for about two hours before being relieved by its mate. The female Black-billed Cuckoo incubates at night, the male taking over again in the morning. In all, the incubation period lasts 10-11 days, beginning with the first egg.

[*Coccyzus erythrophthalmus*, upstate New York, USA. Photo: Robert A. Lubeck/Animals Animals]

Co-operative breeding is restricted, in cuckoos, to the subfamily *Crotophaginae*. *Guira* Cuckoos not only feed in groups but also breed together, several females laying up to 20 eggs in a communal nest. Among the breeding adults, however, competition is great. Irregular markings on the eggs possibly enable each female to single out her own eggs for special care. Adults regularly remove eggs and drop them on the ground, and bury others deep in the nest. In one study in Brazil, 32% of all eggs failed, most having been dropped below the nest. Adults sometimes kill chicks, which in turn may kill other nestlings.

[*Guira guira*,
Pantanal, Brazil.
Photo: Haroldo Palo Jr.]

Cuckoos migrate during the daytime, looking like large flying southern crosses overhead as they move between northern Australia and their wintering grounds further north.

In contrast to these migratory species, most tropical cuckoos are resident and remain throughout the year in their forest area. This is true notably of the ground-cuckoos of both the Old and New Worlds, the Madagascar couas, and the malkohas and many coucals. Some resident cuckoo species, however, exhibit a marked post-breeding dispersal, when they may range far from their natal and breeding areas. The anis occasionally show up at the end of summer in northern North America, more than 1000 km from their breeding grounds, and South American *Guira* Cuckoos have appeared during this same period in the Netherlands Antilles.

Relationship with Man

In much of our literature, the term "cuckold" implies social amorality, in English as in Portuguese, where *cuco* is a man whose wife is unfaithful to him, so that he may be left to care for an offspring that genetically is not his own, much as the foster parents raise a young cuckoo that is not their own offspring. Cuckoos have also been given the reputation of social folly, perhaps based on their neglect of their own family, and to call another person a "cuckoo" is to label him a silly person.

The other widespread role of cuckoos in folklore is as weatherbirds: cuckoos on most continents are known as "rain-birds", because they call incessantly early in the rainy season. To some farmers this suggests that the birds are telling them when to plant, although in fact the cuckoo is calling to other cuckoos and advertising his territory and his availability for a mate. In the present day, this informative role of cuckoos is interpreted in a different way, cuckoos now being regarded as sensitive ecological indicators of environmental degradation. When cuckoos disappear, so do other bird species and also their forest habitats. Cuckoos are secretive, however, and it is usually more obvious that the forests themselves are gone than that the cuckoos have disappeared!

The best known cuckoo in North American folklore is the Greater Roadrunner, also known as the Chaparral Cock, the War Bird, the Medicine Bird, or the Snake-eater of the South-west. Roadrunners have a special status because they kill and eat snakes,

especially, in the popular mind, the poisonous rattlesnakes. One story has it that roadrunners can trap a sleeping rattlesnake by encircling it with joints of prickly cactus. When the bird drops a cactus on the snake, the reptile awakens, tries to escape the cactus corral, and spikes itself on the cactus spines; the roadrunner then eats its captured snake. Although roadrunners do take rattlesnakes, they have never been photographed in the act of building a corral!

The native Americans of the south-west USA see the roadrunners as part of the supernatural world and possessed of great powers. Like other cuckoos, these birds have a zygodactyl foot with two toes forward and two behind, and their footprints leave the sign of a cross. This mark has given the roadrunner a special status among rural folk in areas with Catholic missions. In 1790, an anonymous Franciscan priest in Mexico wrote of "a kind of pheasant which has a long bill, dark plumage, a handsome tail and four feet. It has these latter facing outward in such fashion that when it runs it leaves the track of two feet going forward and two going backward." If we read "toes" instead of "feet", the description is that of the roadrunner. In Hopi culture, the "X" is a design used on kachina figures to keep away evil spirits, which are unable to follow because the direction of travel is unknown. In the Pueblo culture, roadrunner tracks are laid around the house of the dead in order to mislead evil spirits so that they cannot follow the soul of the dead, and at the funeral the relatives and friends mark an "X" on their soles and palms to prevent the dead from following them. They also attach roadrunner feathers to cradle boards and hang the birds' skins over lodge doors for good luck, and to avoid the evil spirits. Although the tracks of the roadrunner form an "X" shape, the direction of travel is nevertheless clear by the length of the toes: the two toe-tracks of nearly equal length point in the direction taken by the bird, and men lost in the desert have followed these tracks to find their own way. In Mexico, roadrunner flesh was thought to have medicinal value, and was eaten to cure itch and boils, to purify blood, and to bring babies.

Roadrunners are respected for their courage, their strength and their endurance, and, because "you are what you eat", the native peoples ate them to gain their strength and swiftness. The Hopi tied roadrunner feathers to their horses' tails for the same reasons. Roadrunners have long been important in this area in

The Red-fronted Coua is a terrestrial bird, but, like other terrestrial cuckoos, it nests in trees. Its nest is much the same as those of other species of coua, a simple bowl of palm fibres, dry stalks and leaves, measuring about 19 cm across and 9 cm high, placed 5-7 m above ground. This is a relatively common coua, mostly inhabiting undisturbed rain forest and dense secondary forest, with a liking for areas of fallen branches.

[*Coua reynaudii*,

rural culture, and they are shown in ancient petroglyphs, prehistoric rock carvings, in Texas and in New Mexico. At present, they are pictured in paintings, jewelry and clothing by the European-derived population of the regional south-west in Arizona, New Mexico and west Texas, although with a less compelling cultural significance. These icons are used across age groups, with school sports teams of young students called "Roadrunners" in Arizona, right through to older people as well who hope to gain the iconic speed, strength and endurance of the roadrunner. The famous animated cartoon, depicting a roadrunner capable of running at incredible and greatly exaggerated speed, is familiar to audiences throughout the world.

Worldwide, the most recognized cuckoo is the Common Cuckoo of the Palearctic, where it has been known since Aristotle's time to be a brood parasite. Cuckoos have featured in the oral traditions and literature in Europe, especially in earlier times when people lived by more rural scripts.

Shakespeare's plays mention the cuckoo as a voice in the wilderness, of little importance, without recognition of his kin and *homo repudiandus* (Prince Hal consorted with Falstaff and the rioters, and neglected his social intercourse with the court):

"So when he had occasion to be seen,
He was but as the cuckoo is in June,
Heard, not regarded--"
(*King Henry IV, Part I*, III, 2, 74-76);

as a brood parasite that destroys its host and family (the Fool, as Lear's daughter Goneril evicts the King and strips him of his dignity):

"For you know, nuncle,
The hedge-sparrow fed the cuckoo so long
That it's had its head bit off by its young.
(*King Lear*, I, 4, 203-205);"

and, again, as a usurper (Worcester to Henry IV, who as Bolingbroke deposed Richard II and gained his crown):

"As that ungentle gull, the cuckoo's bird,
Useth the sparrow--did oppress our nest,

Grew by our feeding to so great a bulk
That even our love durst not come near your sight
For fear of swallowing; but with nimble wing
We were enforced for safety sake to fly
Out of your sight and raise this present head;"
(*Henry IV, Part I*, V, 1, 59-66);

and foremost as a cuckold (the ending refrain, after a game of mate choice has taken a turn of mistaken identity and pairs have become concerned and confused about the sexual fidelity of their mates):

"The cuckoo then, on every tree,
Mocks married men, for thus sings he: Cuckoo!
Cuckoo, Cuckoo! O word of fear,
Unpleasing to a married ear."
(*Love's Labour's Lost*, V, 2, 879-882).

The theme of illegitimacy through cuckoldry (Clown, to Bertram, and cuckoo song) occurs also in *All's Well that Ends Well* (I, 3, 58-61), in the cuckoldry farce of Falstaff in *The Merry Wives of Windsor* (II, 1, 107-121; II, 2, 267-302; III, 3, 38 ff), and by Pompey to Antony, a lover of a faithless woman and a man who will not long remain in power in the land:

"At land indeed
Thou dost o'ercount me of my father's house:
But since the cuckoo builds not for himself,
Remain in't as thou mayst."
(*Antony and Cleopatra*, II, 6, 27, 26-29).

Missing only is an account of the particular mechanism of eviction of host eggs and nestlings by the young cuckoo (although Goneril in *King Lear* comes close). Eviction was not recorded until two centuries later, by E. Jenner in 1788.

Cuckoos are the ultimate changelings, "a child secretly substituted for another in infancy" (*Oxford English Dictionary*); the foster parents rear a young unlike their own. Their changeling properties have been exaggerated, as in the superstition that a sparrowhawk changes into a cuckoo in summer. Aristotle dismissed the myth as incredible, and so it is.

Oral tradition knows the cuckoo as a seasonal migrant which lives in Europe for only a few months of the year:

"Cuckoo, cuckoo, What do you do?
In April, I open my bill;
In May, I sing night and day;
In June, I change my tune;
In July, Away I fly;
In August, Go I must."

Cuckoos are often mentioned in songs, as well:

"The cuckoo is a merry bird,
She sings as she flies;
She brings us good tidings,
And tells us no lies.
She sucks little birds' eggs
To make her voice clear,
That she may sing Cuckoo!
Three months in the year."

Poetry and folk songs also allude to the cuckoo's reproductive performance in laying many eggs in a season:

"Cuckoo, cherry tree,
Lay an egg, give it me,
Lay another, Give it my brother..."

Cuckoos have their social place in folk and rural medicine, although there is no established basis to suppose that they are pharmaceutically useful, not even in the case of the black anis that are used against venereal disease. Nestling coucals are taken by man for medicinal purposes in Borneo: the legs of the chicks are broken, and the adult coucals are said to bring healing herbs which they partly digest and regurgitate to the chicks as a dressing for the legs; then, when the chicks have been healed, they are bottled in spirit and the liquid is used as a cure for many problems, especially rheumatism. Apart from these medicinal uses, cuckoos are not often taken for food. Many are said to be distasteful, although this evaluation, like that of their medicinal value, has a cultural bias. Coucals are occasionally eaten by man in some societies.

In the presence of humans, most cuckoos are shy and skulking, although the anis are often tame and allow a close approach.

Cuckoos are not often kept as pets, and only a few like the Coral-billed Ground-cuckoo and the Guira Cuckoo are kept in zoos at all frequently. They are not crop pests, nor have there been any attempts to control the numbers of the brood-parasitic cuckoos where they might affect the breeding numbers of their hosts. Cuckoos have their most interesting relationships with man as subjects of research for naturalists and biologists, those with an interest in the evolution of mating systems and breeding styles, coloniality, brood parasitism and co-operative breeding.

Status and Conservation

As with many, or perhaps most, of the world's animal species, the population levels of many cuckoos are not known with any degree of accuracy. The best assessments of their relative abundance are generally expressed in such terms as "common", "not uncommon" and so on, and in most cases are derived from non-systematic observations in the field. As is to be expected nowadays, a better indication of the status of a species is normally available only for those with populations that are thought to be in a less healthy condition.

The only cuckoo that in historical times is virtually certain to have become extinct is the Snail-eating Coua (*Coua delalandei*). The largest species of coua, it lived on Île Sainte Marie, a small island on the north-east side of Madagascar. It probably disappeared from Madagascar around 1835 at a time of deforestation, with a secondary cause of extinction being hunting, and perhaps also the introduction of rats which may have adversely affected its food supply, terrestrial snails.

Those cuckoos most at risk of extinction and with numbers in danger of dropping to critically low levels are the species of tropical evergreen forests, and also the island cuckoos with small populations. Apart from the Snail-eating Coua, the species considered most at risk is the Black-hooded Coucal (*Centropus steerii*), confined to Mindoro in the Philippines, where it is considered to be extremely close to extinction, probably as a result mainly of habitat loss and fragmentation. Eight other cuckoos currently reckoned to be threatened with extinction are the Red-faced Malkoha (*Phaenicophaeus pyrrhocephalus*), the Sumatran (*Carpococcyx viridis*) and Bornean Ground-cuckoos (*Carpococcyx radiatus*), the Sunda Coucal (*Centropus nigrorufus*), the Green-billed Coucal (*Centropus chlororhynchus*), the Cocos

All young cuckoos are altricial, but they grow rapidly in the nest. Those reared by their own parents, as is the case of Yellow-billed Cuckoos, leave the nest in as little as ten days, and may fledge a day or two before that. This species and the Black-billed Cuckoo (*Coccyzus erythrophthalmus*) have exceptionally long breeding seasons, extending from about April, when the earliest insectivorous passerines nest, and continuing through to early September in areas where insects are abundant. Both then migrate to South America.

[*Coccyzus americanus*,
Alma, Illinois, USA.
Photo: Richard Day/
Oxford Scientific Films]

The cuckoos most at risk are those living in tropical evergreen forests and those with restricted ranges. Several coucals figure prominently among the list of threatened and near-threatened cuckoo species. The Goliath Coucal, although confined to six islands in the Moluccas, is not currently considered at risk; indeed, it appears even to be common on Halmahera. Nevertheless, it has not been seen recently on two of the six islands of its range, and any further loss of habitat in the remaining islands could easily push it into the danger zone.

[*Centropus goliath*, Halmahera, Moluccas. Photo: Morten Strange]

Cuckoo (*Coccyzus ferrugineus*), the Rufous-breasted Cuckoo (*Hyetornis ruficularis*), and the Banded Ground-cuckoo (*Neomorphus radiolosus*). Of special interest is the Sumatran Ground-cuckoo, which has not been seen since 1916, although it may still persist in the remaining forests of that immense island; its status as a distinct species, recognized years ago but overlooked in recent years, gives additional reason for discovering more about it in the field.

Several other cuckoos are considered near-threatened, especially those with restricted ranges, often limited to islands. These are the Coral-billed Ground-cuckoo, Verreaux's Coua (*Coua verreauxi*), the Kai Coucal (*Centropus spilopterus*), the Biak Coucal (*Centropus chalybeus*), the Short-toed Coucal (*Centropus rectunguis*), the Brown Coucal (*Centropus andamanensis*) and the Rufous Coucal (*Centropus unirufus*); on the same list belongs the race *squamiger* of the Rufous-vented Ground-cuckoo (*Neomorphus geoffroyi*), which is sometimes considered a distinct species.

The status of two cuckoo taxa remains more or less unknown. The Moluccan Cuckoo (*Cacomantis heinrichi*) is known only from five specimens collected in 1931, and has not been recorded since then. The subspecies *rufomerus* of the Little Bronze-cuckoo, sometimes considered a separate species, inhabits six small islands east of Timor, Indonesia; it is very little known. The true status of both of these cuckoos, and the nature of any threats facing them, are unclear.

Cuckoos on small islands are also at risk when they live in areas where tidal waves can destroy large tracts of lowland forest. Lowland and montane forests in the tropics, especially those in Malaysia, Indonesia and the Philippines, are in imminent danger of losing their cuckoos, along with the rest of their diverse array of birds. Preservation of their tropical forest habitats appears to be the best means of maintaining the numbers and diversity of cuckoos, as well as a whole host of other forms of life.

Roadrunners have been persecuted because of their reputation as predators of the eggs and young of *Callipepla* quails. Early in the twentieth century, they were controlled in "chaparral drives", with a federal or state bounty on their heads. Feeding studies have shown, however, that they only rarely include quails in their diets, but they do take crop and household pests, as well as having some cultural status in the North American South-west (see Relationship with Man). Although they carry no official bounty, many Greater Roadrunners are still shot today, illegally, as targets and trophies.

Conservation of the host species which are heavily parasitized by cuckoos appears not to be a problem, in contrast to the situation with certain rare hosts that are parasitized by cowbirds in North America. In normal circumstances, the deteriorating habitat conditions for the host species would drive the cuckoos to local extinction well before the hosts themselves became seriously threatened as a result of cuckoo parasitism, since a population of parasitic cuckoos needs a large number of nesting hosts in order to maintain its numbers from one generation to the next.

Cuckoos depend mainly on insects, especially caterpillars, for their food, and the brood parasites depend on their host populations to rear their young. Environmental disturbances which lead to the reduction of host populations may result in the loss of parasitic cuckoos, and disturbances which lead to the reduction of wooded habitats and insects may also cause a decrease in other cuckoos as well.

Cuckoos may be among the first birds to disappear from a habitat that is polluted by industrial and chemical waste, because their caterpillar prey accumulate toxins from chemical pollution, as well as from the conversion and storage of normal metabolic products. In the early 1970's, migratory cuckoos which killed themselves when they flew into television towers in North America had significant amounts of chlorinated hydrocarbons in their tissues. The concentrations of pesticide metabolites in Yellow-billed Cuckoos were higher in autumn than in spring, and were higher in autumn adults than in juveniles; the time and the context of such concentrations of toxins suggest, therefore, that the pesticides were acquired on the breeding grounds. Anis also are at risk from the pesticides that are applied to kill grasshoppers, their main food.

Finally, Greater Roadrunners have disappeared from urban areas and from the margins of roadways carrying much traffic, as well as suffering from predation and disturbance by feral and domestic dogs and cats around urban and rural areas. Roadrunners require extensive, undisturbed, open shrubby and grassy habitats with abundant populations of reptile and insect prey, and these are commonly destroyed with the development of agriculture, urbanization, and the fragmentation of expansive tracts of grassland and chaparral.

A few cuckoos, both brood parasites and nesting species, have been bred in captivity. These include the Great Spotted and Common Cuckoos, the Greater Roadrunner, and the Coral-billed Ground-cuckoo. They have not, however, been bred on a scale large enough to provide sufficient numbers of individuals for re-introduction into areas from which they have been lost in the wild.

Subfamily CUCULINAE

Genus *CLAMATOR* Kaup, 1829

1. Jacobin Cuckoo

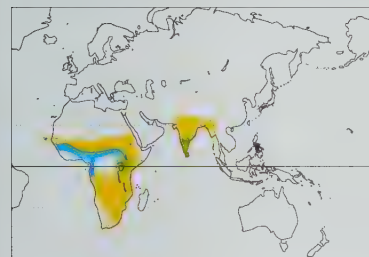

Clamator jacobinus

French: Coucou jacobin **German:** Jakobinerkuckuck **Spanish:** Críalo Blanquinegro
Other common names: Pied (Crested)/Black-and-white Cuckoo

Taxonomy. *Cuculus Jacobinus* Boddaert, 1783, Coromandel Coast. Along with *C. levaillantii* sometimes placed in separate genus *Oxylophus*, owing to differences in plumage and wing shape. Three subspecies recognized.

Subspecies and Distribution.

C. j. serratus (Sparrman, 1786) - S Africa.
C. j. pica (Hemprich & Ehrenberg, 1833) - sub-Saharan Africa S to Tanzania and Zambia, and NW India to Nepal and Myanmar, occasionally S Tibet, in foothills of Mt Everest.
C. j. jacobinus (Boddaert, 1783) - S India and Sri Lanka.

Descriptive notes. 34 cm; 66 g (India), 72 g (S Africa). Adult glossy black above with black crest, white patch on black wings and white tips to black tail; white below; iris brown, bill black, feet slate grey. Juvenile brown to sooty black above, whitish below with fulvous or grey on breast, tail spots buff (not white); iris pale yellow. Races differ in plumage and size: *jacobinus* smaller, *pica* larger, both unstreaked below; *serratus* larger, with two colour morphs, one variably greyish white to white below with streaked throat, the other, mainly in coastal S Africa, all glossy black with white wing patch and no white in tail. Voice. Loud ringing

"kleeuw, kleeuw, kleeuw", each note descending, repeated in series, by both sexes; males often follow with faster series of short rising notes, "kwik-kwik-kwik...", and call "kweek!". Often calls at night.

Habitat. Open woodland and scrub, dry thorn savanna, thorny jungle, plains. In India mainly in lowlands, plains and hills up to 2000 m, on migration to 4200 m in Himalayas; in Africa to 3000 m, but mainly below 1500 m.

Food and Feeding. Insects, mainly hairy caterpillars, also grasshoppers, mantids, termites; forest snails; eggs of host birds; berries. Feeds mainly in trees and bushes, also descends to ground and hops in search of food.

Breeding. Breeds in rains: in N India Jun-Aug, and in S Nilgiris Jan-Mar; in W Africa May-Jul; in Ethiopia Mar-Oct; in E Africa season coincides with the local rains, E of Rift Valley occurring Mar-May, from Rift westwards in Mar-Aug; in S Africa Nov-Mar. Brood-parasitic, with hosts mainly *Turdoides* babblers: in India Common Babbler (*T. caudatus*), Jungle Babbler (*T. striatus*) and Large Grey Babbler (*T. malcolmi*); in Mauritania, Kenya and Ethiopia Fulvous Chatterer (*T. fulvus*) and Rufous Chatterer (*T. rubiginosus*); in S Africa bulbuls (*Pycnonotus*, *Andropadus importunus*) and Fiscal Shrikes (*Lanius collaris*). Eggs blue in India, Sri Lanka and Africa N of 14° S, white in S Africa, rarely white in Mali and Kenya; 24 x 19 mm (India), 27 x 22 mm (S Africa); incubation 11-12 days. Nestlings either eject host's eggs or young or they monopolize food in nest, depending on host species; fledging 17-18 days.

Movements. An intra-African migrant in N and S, arriving on breeding grounds with rains and abundance of caterpillars. In far W Africa, breeds in Mauritania and migrates to Senegal and Gambia, where recent records are all in Nov-Dec; in Mali, present May-Oct; in Togo and Nigeria mainly seasonal, in N in Apr-Sept and in S in dry season; in savanna and forest edge in Gabon, juveniles appear as rare migrants in Dec. In E Africa a diurnal migrant, observed to move NW over Serengeti Plains in Feb-Mar. In S Africa, appears in E Cape in late Oct; moves towards more equatorial woodlands for dry season. Black morph *serratus* appears in austral winter N to Kenya, Ethiopia, Sudan and Chad, occasionally wanders to W Africa. Seasonal with the rains in India, occurring NE India May-Sept and disappearing early in dry season; present in C Myanmar May to early Nov. Nominate *jacobinus* from India winters in E and C Africa. Race *pica* nearly unknown in winter in Asia (one record Nepal), migrates to Africa, where not distinguishable from African *pica*: most Asian migrants move across Arabian Sea and Indian Ocean; more than 20 records in Oman and S Arabia, mainly in migration season; also observed on Seychelles during migration period.

Status and Conservation. Not globally threatened. Reported to be generally common, or at least not uncommon, throughout much of its extensive breeding range, e.g. common in parts of S India in Jul-Aug. No known threats to its numbers or habitats. May have an adverse impact on the breeding success of its host populations: e.g. 36% of Cape Bulbul (*Pycnonotus capensis*) nests were parasitized locally in S Africa.

2. Levaillant's Cuckoo

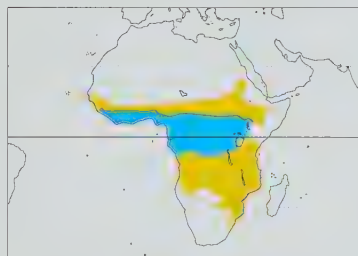

Clamator levaillantii

French: Coucou de Levaillant **German:** Kapkuckuck **Spanish:** Críalo Listado
Other common names: (African) Striped Cuckoo, Striped Crested Cuckoo

Taxonomy. *Coccyzus levaillantii* Swainson, 1829, Senegal.

Along with *C. jacobinus* sometimes placed in separate genus *Oxylophus*, owing to differences in plumage and wing shape. Formerly listed as *C. cafer*, but that species name was in fact applicable instead to *Cuculus clamosus*. Monotypic.

Distribution. Africa S of Sahara, breeding Sahel to E and S Africa. In non-breeding season ranges to C Africa and coastal W Africa.

Descriptive notes. 39 cm; 124 g. Adult glossy black above with black crest, white patch on black wings and white tips to black tail; white below, streaked black on throat and breast; iris brown, bill black, feet blue-grey; also rare melanistic morph in coastal E Africa, all black but for white wing patch and tail tips. Juvenile brown to rufous above, wings black with white patch, tail grey with paler tip; whitish below with dull brown on breast, some with black streaking on breast; iris pale grey, gape bright red-orange. Voice. Ringing "kuwu-weer, kuuu-weer..." often ending with rapid "kwik'kwik'kwik...", similar to *C. jacobinus* but longer, louder and harsher.

Juvenile begging call differs from that of host's young.

Habitat. Open woodland, wooded savanna, thickets, gardens, riverine forest, scrub, and even in forest canopy; often in humid habitats, in E Africa mainly in areas with more than 500 mm rainfall. Occurs at up to 2000 m in E Africa.

Food and Feeding. Insects, mainly hairy and spiny caterpillars, also winged termites, beetle larvae, grasshoppers. Foraging behaviour much as for *C. jacobinus*.

Breeding. Breeds mainly in rains: in Gambia Jun-Nov, in Sierra Leone Sept, in Ghana Feb-Jun, in Nigeria Apr-Sept (-Nov), in Ethiopia Jun-Sept, in Kenya Mar-May, in Malawi and Zimbabwe Dec-Apr (occasional young to June). Brood-parasitic: hosts mainly *Turdoides* babblers, including Brown Babbler (*T. plebejus*), Black-capped Babbler (*T. reinwardtii*), Arrow-marked Babbler (*T. jardineii*), Bare-cheeked Babbler (*T. gymnogenys*); also, fledged young fed by Chestnut-bellied Starling (*Spreo pulcher*). Eggs pale blue, in Nigeria pink with darker speckles, colour matches host eggs but surface texture more pitted than that of babblers' eggs; 26 x 21 mm; embryo develops for a day while egg in oviduct; incubation 12 days. Nestling does not evict; babbler host's young sometimes fledge from same nest as cuckoo; fledged cuckoo fed by foster parents for at least 36 days.

Movements. Intra-African migrant; seasonal in S Africa, resident or partly migratory in equatorial regions. Distinct black morph occurs Mar-Sept in coastal Kenya. Seen mainly in rainy season; in W Africa moves into northern woodlands with rains and into S Guinea woodlands for dry season, though in Sierra Leone some birds present in all habitats throughout year. In Gabon, non-breeders appear in dry season in Dec.

Status and Conservation. Not globally threatened. Generally not uncommon throughout range. Common and conspicuous parasitic cuckoo in Gambia and the upper R Niger in Mali during the rains; widespread and not uncommon in Sierra Leone. Locally common in S of range, but said to be rare in N Tanzania.

Bibliography. Bannerman (1953), Benson & Benson (1977), Benson *et al.* (1971), Britton (1980a), Brown & Britton (1980), Cave & Macdonald (1955), Chapin (1939), Cheke & Walsh (1996), Christy & Clarke (1994), Clarke & Clarke (1985), Colston & Curry-Lindahl (1986), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood, Fry & Dowsett (1973), Elgood, Heigham *et al.* (1994), Friedmann (1956, 1964a), Fry *et al.* (1988), Ginn *et al.* (1989), Giraudoux *et al.* (1988), Gore (1990), Greig-Smith (1976), Grimes (1987), Jensen & Jensen (1969), Jones (1985), Lamarche (1980), Lewis & Pomeroy (1989), Lippens & Wille (1976), Lorber (1984b), Mackworth-Praed & Grant (1957, 1962, 1970), Maclean (1993), Moore (1984), Mundy (1973), Nikolaus (1987), Penry (1994), Pinto (1983), Rowan (1983), Serle (1977), Sharland & Serle (1977), Short *et al.* (1990), Snow (1978), Steyn (1973), Steyn & Howells (1975), Vernon (1982), Zimmerman *et al.* (1996).

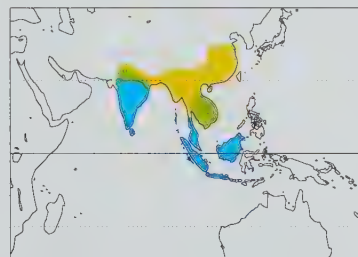

3. Chestnut-winged Cuckoo

Clamator coromandus

French: Coucou à collier **German:** Koromandelkuckuck **Spanish:** Críalo Oriental
Other common names: Chestnut-winged Crested/Red-winged (Crested) Cuckoo

Taxonomy. *Cuculus coromandus* Linnaeus, 1766, Coromandel. Monotypic.

Distribution. N India and Nepal E to S & E China and Indochina, S to S Myanmar (Tenasserim) Winters S to Greater Sundas.

Descriptive notes. 46 cm; 77 g. Adult metallic glossy black above, black crest, white nape, wings chestnut, tail black; chin to upper breast rusty, belly white; iris pale brown to dark brown to red, bill black with grey gonys, tarsi greyish green. Juvenile brown above with rufous buff feather edges, buff edge to wing-coverts, tail with buff tip and edge; white below; at 5 weeks brown crest with dark buff tip appears; moults to adult plumage at 3 months. Voice. Loud, harsh screech, "creech-creech-creech", and a hoarse whistle.

Habitat. Thick, low vegetation in wooded country, scrub and bushes, cultivated lands and vilt-

lages; also mangroves in winter and on migration. Occurs at altitudes of up to 2450 m.

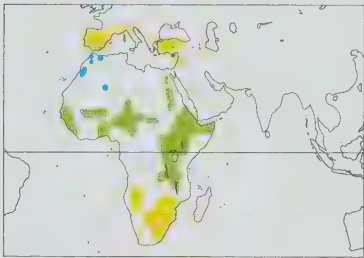

On following pages: 4. Great Spotted Cuckoo (*Clamator glandarius*); 5. Thick-billed Cuckoo (*Pachycoccyx audeberti*); 6. Sulawesi Hawk-cuckoo (*Cuculus crassirostris*); 7. Large Hawk-cuckoo (*Cuculus sparveroides*); 8. Common Hawk-cuckoo (*Cuculus varius*); 9. Moustached Hawk-cuckoo (*Cuculus vagans*); 10. Hodgson's Hawk-cuckoo (*Cuculus fugax*); 11. Philippine Hawk-cuckoo (*Cuculus pectoralis*).

Food and Feeding. Large insects, mainly caterpillars, beetles, mantids, ants, also spiders.
Breeding. Breeds in rains: in India Apr-Aug, in Sri Lanka Jun-Oct. Brood-parasitic: hosts mainly laughingthrushes (*Garrulax*). Eggs pale blue, unmarked, often more than one in a nest; 27 x 23 mm. Few other reliable data.
Movements. Seasonal in summer in China, Nepal and N Myanmar, where it arrives May and departs Oct; probably also only breeding visitor to N & C Thailand, wintering in peninsular Thailand and farther S; migrant in Malaysia. Resident in N India, S Vietnam and perhaps other parts of Indochina, and on Hainan; winters in C & S India, Sri Lanka, Malay Peninsula, Sumatra, Java and Borneo, occasionally to Bangka, N Sulawesi and the Philippines. Vagrant in Japan and Hong Kong.
Status and Conservation. Not globally threatened. Although population levels are inadequately known, species appears to be rather uncommon. It is very local in Nepal, but fairly common where it does occur. In Thailand it is uncommon at all seasons, and in Vietnam it is said to be rather rare. In its non-breeding range, this cuckoo is seen only occasionally in Borneo and Sumatra, and is rare in Java.
Bibliography. Ali & Ripley (1981), Ali *et al.* (1996), Baker (1906-1907), Becking (1981), Cheng Tsohsin (1987), Coates & Bishop (1997), Deignan (1945), Dickinson *et al.* (1991), Échécopar & Hùe (1978), Friedmann (1964a), Harvey (1990), Junge & Kooiman (1951), Legge (1880), Lekagul & Round (1991), MacKinnon & Phillips (1993), Majumdar *et al.* (1992), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986), Osmaston (1916), Phillips (1978), Ripley (1982), Roberts, T.J. (1991), Smythies (1981, 1986), Sody (1989), Stepanyan (1995), Stresemann & Stresemann (1969), White & Bruce (1986).

4. Great Spotted Cuckoo
Clamator glandarius

French: Coucou geai German: Häherkuckuck Spanish: Críalo Europeo

Taxonomy. *Cuculus glandarius* Linnaeus, 1758, northern Africa and southern Europe = Gibraltar. A smaller race, *choragium*, has been described from S Africa, but breeding birds there overlap considerably in size with breeding birds in Mediterranean zone, and are not distinguishable. Monotypic.
Distribution. Iberian Peninsula, S France and W Italy; Turkey and Cyprus E to N Iraq and W Iran, and S through Middle East to Egypt; also sub-Saharan Africa from Senegal and Liberia E to Sudan, Eritrea, Ethiopia, N Somalia and Kenya, and S to Tanzania, Angola and South Africa. Virtually all populations winter in Africa; regular in small numbers in S Spain.

Descriptive notes. 35-39 cm; 124 g. Adult dusky brown above with white feather tips, flight-feathers grey-brown, tail tipped white, crown grey with slight crest, face blackish; throat buff, otherwise white below; eye-ring grey to reddish, iris brown, bill black, feet black. Juvenile has crown and face black, flight-feathers rufous, underparts more buffish; in 1st spring/summer, following arrested moult, intermediate plumage with mix of rufous and grey-brown flight-feathers. Voice. Harsh guttural "gah-gah-gah...gah-gah-gah...ko-ko-ko-ko", the series falling in pitch and increasing in tempo; also trilled "krrrrr" and cackled notes.

Habitat. Semi-arid open woodland, especially acacia thorn-scrub, also other scrub, rocky hillsides in dry savannas; also dry cultivation, e.g. in Middle East. In Europe favours savanna-like heathland, often with cork oak (*Quercus suber*) or stone pine (*Pinus pinea*), also olive groves. Mainly between 500 m and 2000 m.

Food and Feeding. Insects, mainly large hairy caterpillars, also termites, grasshoppers, moths and small lizards; dresses caterpillars by removing hairs before eating. Often feeds on ground.

Breeding. Breeding season late Apr to early Jun in Mediterranean; in Africa, breeds Mar in Egypt, Apr-May in Senegal and Sierra Leone, Apr-Jul in Mali, Ghana and Nigeria; in E Africa breeding varies with local rainy seasons, E of Rift in Apr and Oct-Dec, in arid NW in Feb-Apr; Oct-Jan in S Africa, Dec-Mar in Namibia, into Apr in Botswana. Brood-parasitic: hosts crows and magpies in Mediterranean, particularly Black-billed Magpie (*Pica pica*), Azure-winged Magpie (*Cyanopica cyanea*) and Carrion Crow (*Corvus corone*) in Spain, *C. corone* in Egypt, Pied Crow (*Corvus albus*) in Africa (Senegal, Sierra Leone, Mali, Nigeria, E Africa, S Africa); in W, E and S Africa, also starlings that nest in holes in trees (*Lamprolaima*), in rocks (*Onychognathus*) and in tunnels in sandy banks (*Spreo bicolor*). Female can lay 12-25 eggs in a season. Eggs pale greenish with brown and grey marks; 33 x 24 mm; do not vary with size or colour of host's eggs in Mediterranean; often several cuckoo eggs in one crow nest. Female may damage host's eggs by dropping its own egg on top; magpies sometimes remove cuckoo eggs from nest, crows do not. Incubation 12-15 days, shorter than host; chick naked, yellow or pink at hatching, gape pink, palate spicules not contrasting in colour; does not evict; reaches 50% of fledging weight 8 days after hatching; when more than one cuckoo chick in magpie nest, younger one may starve. Begging call somewhat like that of host species. Fledges in 19-26 days, fed by foster parents for further 25-59 days; fledglings form social groups and are attended by several magpies. Fledging success varies with time of laying, from 92% (eggs laid when host has only 1-3 eggs) to 10% (host's clutch complete); survival of young to independence 63%.

Movements. Adults leave breeding area in Spain in mid Jun, juveniles leave between early Jul and early Aug independently of adults. European birds mostly migrate to Africa, wintering N of 10°N, but possibly many move S of Sahara: small numbers winter in S Spain. Movements throughout range inadequately known, since breeding and non-breeding birds are indistinguishable. Birds in W Africa appear to be local migrants, though some are resident in Senegal; occurrence in Gambia irregular, involving mostly juveniles from farther N, but occasionally breeds; apparently random occurrence throughout much of Sierra Leone. Species is present locally in E Africa all year, and local migrants occur here as well, notably in passage across Serengeti Plains Jan-March. Local movements occur in relation to rains and aridity; birds S of Zambezi are mostly migratory, but a few remain all year in E Cape region of S Africa. In Israel/Palestine, local breeders arrive mid December to end of March, most having left by Jun, with passage of populations from farther N noted late Jan to end of May and Jul-Nov; occasional migrants recorded Arabia. Rare winter records from Middle East. Vagrant to Britain, N Europe and Russia.

Status and Conservation. Not globally threatened. Generally uncommon throughout most of its range, but conspicuous where it does occur. About 500 pairs estimated to breed in Israel/Palestine in 1980's. Species is expanding its range in S Europe and the Middle East, though has decreased in numbers in Egypt, where now rare as a breeding bird. Has also disappeared as a breeder from NW Africa. This species does not affect the success of young crows, but magpie chicks grow more slowly and fledge at lower weights in parasitized nests than in unparasitized ones.

Genus *PACHYCOCCYX* Cabanis, 1882

5. Thick-billed Cuckoo
Pachycoccyx audeberti

French: Coucou d'Audebert German: Dickschnabelkuckuck Spanish: Críalo Piquigrueso

Taxonomy. *Cuculus Audeberti* Schlegel, 1879, Ambodikilo, Antongil Bay, Madagascar. Three subspecies recognized.
Subspecies and Distribution.
P. a. brazzae (Oustalet, 1886) - Sierra Leone patchily through Ghana, Nigeria and Cameroon to Congo and W Zaïre.
P. a. validus (Reichenow, 1879) - E Zaïre to SE Kenya and Tanzania, and S through Malawi, Zambia, Zimbabwe and Mozambique to E Transvaal.
P. a. audeberti (Schlegel, 1879) - Madagascar.

Descriptive notes. 36 cm; 115 g. Adult uniform slate-grey above (brown in worn plumage), lores white, wings blackish, tail barred brown and black; white below; narrow eye-ring yellow, iris brown; bill all blackish, or with yellow/green or yellow-based lower mandible, or all yellow. Juvenile dark brown above with broad white spots on back and wing, face black and white. Race *audeberti* largest; *validus* smaller, lower mandible green-based; *brazzae* smaller, blacker above, no white on lores. Voice. Loud whistled "wheee-wheee-weep", like a goshawk (*Accipiter*); also a chattering "chee-cher-cher-cher".

Habitat. Miombo (*Brachystegia*) woodlands, lowland and riverine forests; more characteristic of rich miombo woodland than closed-canopy evergreen forest. In E Africa, in 500+ mm rainfall area.

Food and Feeding. Insects, mainly hairy caterpillars, marula worms, grasshoppers and mantids.

Breeding. Breeds Sept-Mar in Zimbabwe; few records elsewhere. Brood-parasitic: hosts Red-billed Helmet-shrike (*Prionops retzii*), in Zaïre once White-crowned Helmet-shrike (*P. plumata*); hosts unknown in Madagascar, but Chabert Vanga (*Leptopteryx chaberti*) suspected. Eggs pale blue-green with large brown, grey and lilac blotches; 24 x 17 mm; incubation 13 days. Nestling naked at hatching, skin orange, bill yellow, gape orange, yellow eye-ring by 18 days, does not resemble host's chicks; evicts host's eggs and nestlings; fledges in 28-30 days, fed for up to 50 days after.

Movements. Non-migratory, or with local seasonal movements. In Sudan, possible non-breeding visitor only in S. In Togo, rare resident; in Nigeria, resident near Kagara, where observed in all seasons.

Status and Conservation. Not globally threatened. Uncommon to rare throughout range, though regular in coastal forest of Kenya and locally in SE Zimbabwe; status uncertain in Sierra Leone, with 1-2 pairs reported from Gola Forest, but otherwise only three records. N nominate race, confined to Madagascar, was not seen for many years and was believed to be possibly extinct; but in 1992, at Maromiza forest near Périnet-Analamazaotra Special Reserve, one responded to playback of vocalizations recorded in Africa, giving calls nearly identical to those of the African bird. Further research is required on all three subspecies, to elucidate their true status.

Bibliography. Allport & Fanshawe (1994), Bannerman (1953), Benson & Benson (1977), Benson & Irwin (1972, 1973, 1980), Benson, Brooke *et al.* (1971), Benson, Colebrook-Robjent & Williams (1976-1977), Berlioz (1948), Britton (1980a), Brooke (1984a), Cave & Macdonald (1955), Cheke & Walsh (1996), Clancey (1985), Dowsett & Forbes-Watson (1993), Dyer *et al.* (1986), Elgood *et al.* (1994), Friedmann (1948a), Fry *et al.* (1988), Ginn *et al.* (1989), Grimes (1987), Jensen & Jensen (1969), King (1978/79), Langrand (1990), Langrand & Sinclair (1994), Lewis & Pomeroy (1989), Louette (1989), Mackworth-Præd & Grant (1957, 1962, 1970), Maclean (1993), Milon *et al.* (1973), Pinto (1983), Riddell (1994), Rowan (1983), Short *et al.* (1990), Snow (1978), Vernon (1971b, 1971c, 1984), Zimmerman *et al.* (1996).

Genus *CUCULUS* Linnaeus, 1758

6. Sulawesi Hawk-cuckoo
Cuculus crassirostris

French: Coucou des Célèbes German: Minahassakuckuck Spanish: Cuco de Célebes
Other common names: Celebes Hawk-cuckoo

Taxonomy. *Hierococcyx crassirostris* Walden, 1872, northern Sulawesi.

Often placed in genus *Hierococcyx*, along with other hawk-cuckoos, on grounds of notable morphological differences from *Cuculus*. Monotypic.

Distribution. Mountains of N & C Sulawesi.

Descriptive notes. 34 cm. Adult grey-brown above, outer wing not banded, head grey; white below with black bars; tail barred black, rufous and white; eye-ring yellow, iris dark brown; bill brown to black with greenish base; feet yellow. Juvenile more rufous above, head black; buffy-white below. **Voice.** Far-carrying "to-ko-kuu" or "ka-ka-ku", first syllable sometimes omitted, second higher and louder than third; heard at dawn and dusk, also at midnight.

Habitat. Primary montane forest at 500-1400 m.

Food and Feeding. Insects, including termites.

Breeding. No information.

Movements. Apparently resident. Presumably

some local dispersive movements.

Status and Conservation. Not globally threatened. Generally uncommon, with density of under 1 individual/km, where it occurs; frequently heard at various sites in primary forest of Dumoga-Bone National Park in mid-1980's. Because of its restricted range, was formerly considered near-threatened. Owing to its secretive habits, this species, like other hawk-cuckoos, can be difficult to observe, but its loud voice may be a better clue to its possible presence. It seems unlikely, therefore, that it is any commoner than current fieldwork suggests.

Bibliography. Andrew (1992), van den Berg & Bosman (1986), Coates & Bishop (1997), Holmes & Philipps (1996), Inskipp *et al.* (1996), Jepson (1997), Rozendaal & Dekker (1989), Stresemann (1940), Sujatnika *et al.* (1995), Watling (1983), Wheatley (1996), White & Bruce (1986).

7. Large Hawk-cuckoo

Cuculus sparverioides

French: Coucou épervier

German: Sperberkuckuck

Spanish: Cuco Grande

Other common names: Brain-fever Bird

Taxonomy. *Cuculus sparverioides* Vigors, 1832, Himalayas.

Often placed in genus *Hierococcyx*, along with other hawk-cuckoos, on grounds of notable morphological differences from *Cuculus*. Two subspecies recognized.

Subspecies and Distribution.

C. s. sparverioides Vigors, 1832 - Himalayas from N Pakistan and India to Nepal, Naga Hills and Manipur, whence E to China (Sichuan and lower Yangtze valley), and S to Myanmar, Thailand and Indochina; winters mainly from Bangladesh and Thailand S to S & E India and Greater Sundas, and E to Philippines.

C. s. bocki (R. G. W. Ramsay, 1886) - mountains of Malaysia, Sumatra and Borneo.

Descriptive notes. Nominata 38-40 cm; 150 g. Adult brown above, ashy-grey on crown, nape and neck, tail barred brownish grey and black; chin black, throat white and breast more rufous, both dark-streaked, belly white with blackish bars; eye-ring yellow, iris orange to buff, bill blackish above and greenish slate below. Subadult streaked below. Juvenile barred rufous and brown above, forehead grey, nape white, tail barred rufous and black; buff below, streaked with blackish teardrops. Race *bocki* considerably smaller, with narrow rufous bars above, throat unstreaked, rufous breast often unstreaked.

Voice. In breeding season, calls in mornings and at sunset into night, a loud, shrill screaming whistle, "brain fe-ver" or "pi-pee-ha", increasing in speed and pitch to frantic climax. Song may differ between the two races.

Habitat. Deciduous and evergreen wooded areas, especially with oaks, also in pine woods in Sumatra, mostly at higher elevations; on passage and in winter, also in mangroves, gardens, often at lower levels. Breeds at 900-2700 m in Indian subcontinent, to 3000 m in Nepal, 900-1600 m in Sumatra, and in mountains above 1000 m in Borneo.

Food and Feeding. Insects, mainly caterpillars; also crickets, grasshoppers, beetles, bugs, roaches, ants and spiders; also berries. Forages solitarily in trees, where remains in canopy.

Breeding. Breeds Jun-Jul in W Himalayas, Apr-Jun in Assam. Brood-parasitic: hosts in India laughingthrushes (*Garrulax*), also Large Spiderhunter (*Arachnothera magna*), Nepal Shortwing (*Brachypteryx leucophrys*), in Sumatra, Chestnut-capped Laughingthrush (*Garrulax mitratus*). Eggs (1) light brownish olive, seldom with darker specks, (2) blue; 27 x 19 mm. Few other reliable data.

Movements. Race *bocki* resident. Race *sparverioides* mainly migratory: most individuals, at least from N of range and in most of China, move S to winter from peninsular India, Bangladesh, Thailand and Peninsular Malaysia, through the Greater Sundas (scarce Sumatra; rare Java, Bali, Borneo), to the Philippines; resident in Hainan, N Thailand and probably E Myanmar. Apparently only a vagrant to N Sulawesi.

Status and Conservation. Not globally threatened. Common or fairly common breeder in many parts of range, notably Thailand, Nepal and Borneo, but scarce in Sumatra; rare and local passage and winter visitor in Philippines.

Bibliography. Ali & Ripley (1981), Ali *et al.* (1996), Baker (1906-1907, 1907), Becking (1981), Cheng Tsohsin (1987), Coates & Bishop (1997), Deignan (1945), Dickinson *et al.* (1991), Étiénnepour & Hùe (1978), Fan Qiangdong (1988), Holmes (1996), Lekagul & Round (1991), MacKinnon & Philipps (1993), Madoc (1976), van Marle & Voous (1988), Mason (1990), Medway & Wells (1976), Osmaston (1916), Parkes (1973), Ripley (1982), Roberts, T.J. (1991), Robinson *et al.* (1924), Schönwetter (1967), Smythies (1981, 1986), Sody (1989), Stepanyan (1990b, 1991, 1995), Thompson *et al.* (1993), White & Bruce (1986).

8. Common Hawk-cuckoo

Cuculus varius

French: Coucou shikra

German: Wechsellkuckuck

Spanish: Cuco Chikra

Other common names: Ceylon Hawk Cuckoo, Brain-fever Bird

Taxonomy. *Cuculus varius* Vahl, 1797, Tranquebar, India.

Often placed in genus *Hierococcyx*, along with other hawk-cuckoos, on grounds of notable morphological differences from *Cuculus*. Two subspecies recognized.

Subspecies and Distribution.

C. v. varius Vahl, 1797 - India, Nepal, Bangladesh and Myanmar.

C. v. cicellae (Phillips, 1949) - Sri Lanka.

Descriptive notes. 33 cm; 104 g. Adult ashy brownish grey above, paler on head, tail with 3-5 whitish and black bars and light rufous tip; white below, with pale rufous breast and bars on abdomen and flanks; eye-ring pale grey, iris yellow, bill yellowish above and greenish below, feet yellow. Differs from *C. sparverioides* in smaller size, less distinct barring below, and voice. Juvenile, barred dull rufous above, tail lacks whitish; brown-streaked buffy-white below. Race *cicellae* darker, and with barred breast. **Voice.** Loud shrieking "brain fé-ver" or "wee-piwhit", in runs of 4-6, becoming higher and louder, more shrill than *C. sparverioides*; female

gives strident trilling scream. Often sings at night, with bright moon.

Habitat. Wooded country, in deciduous and semi-evergreen forests, gardens, groves of cultivated trees. In both plains and hill country, below 1000 m in Nepal.

Food and Feeding. Insects, mainly caterpillars and cutworms, also grasshoppers, locusts, winged termites, ants; lizards; fruits of wild banyan fig, berries. Arboreal and secretive forager.

Breeding. Breeds Mar-Jul in India, Jan-Apr in Sri Lanka. Brood-parasitic: hosts babblers, including Jungle Babbler (*Turdoides striatus*) and laughingthrushes (*Garrulax*). 2 oviduct eggs were blue, 27 x 20 mm. Young evicts host's chicks. Call of fledged juvenile "ke-ke", like that of babbler.

Movements. Mostly resident; also partially migratory at higher altitudes and in drier habitats. Single vagrants Oman and Thailand.

Status and Conservation. Not globally threatened. Common on the plains of India, where characteristic call is amongst the most widely known of bird sounds; also common in Nepal, but rare in Sri Lanka; status in Bangladesh and Myanmar uncertain.

Bibliography. Ali (1996), Ali & Ripley (1981), Ali & Whistler (1937), Ali *et al.* (1996), Baker (1906-1907), Becking (1981), Foster (1989), Grewal (1995), Harvey (1990), Henry (1971), Himmatsinhi (1980), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Kotagama & Fernando (1994), Legge (1880), Lushington (1949), Mahabal & Lamba (1987), Majumdar *et al.* (1992), Meston (1942), Mukherjee (1995), Phillips (1948, 1978), Ripley (1982), Roberts, T.J. (1991), Saha & Dasgupta (1992), Schönwetter (1967), Smythies (1986), Wijesinghe (1994).

9. Moustached Hawk-cuckoo

Cuculus vagans

French: Coucou à moustaches

German: Bartkuckuck

Spanish: Cuco Bigotudo

Other common names: Lesser/Small/Dwarf Hawk-cuckoo

Taxonomy. *Cuculus vagans* S. Müller, 1845, Java.

Often placed in genus *Hierococcyx*, along with other hawk-cuckoos, on grounds of notable morphological differences from *Cuculus*. Monotypic.

Distribution. S Myanmar and Mergui Archipelago, S Thailand, S through Peninsular Malaysia to Sumatra and Borneo; recent records from S Laos.

Descriptive notes. 26 cm; 56 g. Adult dark brown above, crown dark grey, cheek and throat whitish, broad black moustache, tail barred grey and black, wings barred lighter brown; inner webs of inner flight-feathers and coverts whitish, form pale patch from above in flight; whitish below with dark streaks; eye-ring yellow, iris dark brown; bill blackish above, base greenish, yellow-green below; feet yellow. Juvenile has crown brown. **Voice.** Two-syllable phrase, "kang koh", repeated every 2 sec; also mellow whistle, "peu peu", ascending on scale to sudden stop.

Habitat. Forest edge and secondary forest, especially lower hill slopes and lowlands, alluvial

forest, bamboo forest. In Thailand, from plains to 900 m.

Food and Feeding. Insects.

Breeding. In Malaysia, singing peaks in Feb and a juvenile seen in Jul. Brood-parasitic: hosts unknown. No information on breeding biology.

Movements. Resident and partially migratory; details unknown.

Status and Conservation. Not globally threatened. Like all forest species, may be vulnerable to further deforestation as is the case in Thailand, where species is considered an uncommon resident. Rare in Sumatra and Borneo, and only occasional vagrant to W Java. Recent observations of this species in Laos may possibly indicate slight range expansion, but equally may be due to better coverage.

Bibliography. Andrew (1992), Duckworth (1996), Gibson-Hill (1949), Holmes (1996), Holmes & Burton (1987), Inskipp *et al.* (1996), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Philipps (1993), van Marle & Voous (1988), Medway & Wells (1963, 1976), Rajathurai (1996), Round (1988), Smythies (1981, 1986), Thewlis *et al.* (1996), Wilkinson, Dutson & Sheldon (1991), Wilkinson, Dutson, Sheldon, Noor & Noor (1991).

10. Hodgson's Hawk-cuckoo

Cuculus fugax

French: Coucou fugitif

German: Fluchtkuckuck

Spanish: Cuco Huidizo

Other common names: Fugitive/Horsfield's Hawk-cuckoo

Taxonomy. *Cuculus fugax* Horsfield, 1821, Java.

Often placed in genus *Hierococcyx*, along with other hawk-cuckoos, on grounds of notable morphological differences from *Cuculus*. Forms a superspecies with *C. pectoralis*, with which often considered conspecific (see page 512). Three subspecies recognized.

Subspecies and Distribution.

C. f. niscolor Blyth, 1843 - Nepal and E Himalayas to Myanmar, Thailand, Annam and Hainan; winters S to Sumatra, Java and Borneo.

C. f. fugax Horsfield, 1821 - S Thailand, Peninsular Malaysia, Sumatra, Java and Borneo.

C. f. hyperythrus Gould, 1856 - Sichuan E to NE China and Ussuriland (Sikhote-Alin), and S to Korea, S Japan (Hondo) and lower Yangtze valley; migrates to S China, SE Asia, Borneo and Sulawesi.

Descriptive notes. 28-30 cm; 83 g. Adult slate-grey above, wings brownish, inner webs of inner flight-feathers and coverts white barred grey-brown and inner secondaries unbarred pale grey (form pale patch from above in flight), tail banded grey and black with broad black subterminal bar and rufous and white tip; white moustache and supraloral area; whitish below, streaked with rufous and brown, chin grey, throat white, flanks light rufous, undertail-coverts white; eye-ring yellow, iris yellow, bill yellow with black tip to greenish to black, feet yellow. Subadult dark grey above, barred rufous, crown black with buff feather tips; whitish below with

rufous-edged dark brown spots or streaks. Juvenile with upperpart feathers edged buff, tail with broader white tip; streaked and spotted black below; eye-ring yellow, iris grey (some with brown ring), bill black. Race *fugax* large-billed, with most rounded wingtip; *nisicolor* smaller-billed, wing more pointed, whitish below with pale rufous-brown streaks; *hyperythrus* largest-bodied, wing more pointed, white nape patch, breast and belly pale rufous with very fine grey streaks. VOICE. Calls through night, shrill "gee-whizz, gee-whizz", first note higher-pitched than second, repeated up to 20 times, and rapid sequence of shrill "pee" notes rising up scale and dropping at end.

Habitat. Deciduous semi-evergreen and evergreen forests, secondary forest, damp ravines covered with conifers, bamboo thickets and plantations. Breeds 600-1800 m in India, to 1000 m in Myanmar, to 1400 m in Sumatra, to 2300 m in Japan, to 2800 m in Borneo.

Food and Feeding. Insects, mainly caterpillars, cicadas, beetles, also fruits and berries. Active in bushes and understorey.

Breeding. Oviduct egg in Jun (Sikkim); possibly Jun-Sept. Brood-parasitic: hosts in India are Nepal Shortwing (*Brachypteryx leucophrys*) and Small Niltava (*Niltava macgrigoriae*); in Borneo Black-throated Babbler (*Stachyris nigricollis*); in Japan include Blue Chat (*Eritacus cyane*). Eggs uniform olive-brown to green, darker at large end, 24 x 16 mm (India and Sikkim); pale blue, 28 x 20 mm (Japan).

Movements. Migratory in N part of range, races *nisicolor* and *hyperythrus* almost entirely vacating their breeding ranges to winter S to Sumatra, Java and Borneo, where overlap occurs with resident *fugax*. Migrant through Peninsular Malaysia, and also recorded on passage through Korea. Recently recorded on Bali, where status uncertain.

Status and Conservation. Not globally threatened. This species is considered uncommon in Japan and China, uncommon in Thailand, and rare in Vietnam and in Java. Clearly rare also in Nepal, with only two records. Few records known from Myanmar, and species only occasionally reported from Borneo but said to be locally common in Bornean mountains. May be common in Peninsular Malaysia. Although the species has been recorded recently in Bali, it is not certain whether this involves breeding or wintering.

Bibliography. Ali & Ripley (1981), Baker (1906-1907), Becking (1981), Brazil (1991), Coates & Bishop (1997), Cranbrook & Wells (1981), Deignan (1945), Dementiev & Gladkov (1951a), Échécopar & Hùe (1978), Fiebig (1995),

Flint *et al.* (1984), Gore & Pyong-Oh (1971), Higuchi & Sato (1984), Inoue (1949, 1958), Junge (1948), Knystautas (1993), Lekagul & Round (1991), Li (1991), MacKinnon & Phillipps (1993), van Marle & Voous (1988), Mayr (1938), Medway & Wells (1976), Mees (1986), Ripley (1942, 1944, 1982), Robinson *et al.* (1924), Siebers (1930), Smythies (1981, 1986), Sody (1989), Stepanyan (1990a, 1995), Thewlis *et al.* (1996), Thompson (1966), Tomek (1985).

11. Philippine Hawk-cuckoo

Cuculus pectoralis

French: Coucou des Philippines

German: Philippinenkuckuck

Spanish: Cuco Filipino

Taxonomy. *Hiracoccyx pectoralis* Cabanis and Heine, 1863, Philippines.

Often placed in genus *Hierococcyx*, along with other hawk-cuckoos, on grounds of notable morphological differences from *Cuculus*. Forms a superspecies with *C. fugax*, with which often considered conspecific (see page 512). Monotypic.

Distribution. Philippines, on Palawan, Luzon, Mindoro, Sibuyan, Cebu, Negros, Leyte and Mindanao.

Descriptive notes. 28 cm; 80 g. Adult slate-grey above, white loreal streak, wings round-tipped, brownish, inner webs of inner flight-feathers and coverts white barred grey-brown and inner secondaries unbarred pale grey (form pale patch from above in flight), tail banded grey and black with broad subterminal black band and rufous tip; chin grey, throat white, breast bright rufous (with or without fine grey streaks), belly and undertail-coverts white; eye-ring yellow, iris yellow to brown, bill black above, olive below, feet yellow. Subadult barred rufous on back and wings, chin white, white below with rufous-edged black teardrop streaks, tail barred grey,

brown and rufous. Juvenile with head blackish with buff feather edges, nape white, chin streaked, rufous wash on chest, iris pale brown. VOICE. Series of short crescendo calls rising and falling in pitch, each phrase of 6-8 notes/sec, also prolonged crescendo call rising then falling, unlike *C. fugax* (Thailand and Malaysia).

Habitat. Forest: virgin mossy to dipterocarp. Up to 2400 m.

Food and Feeding. Insects, mainly caterpillars, also berries.

Breeding. Virtually unknown. Females may lay in subadult plumage. Brood-parasitic: hosts unknown.

Movements. Resident.

Status and Conservation. Not globally threatened. An uncommon to rare resident of dense original forest, a habitat which is rapidly disappearing throughout the Philippines. Although species is not currently considered threatened, this may perhaps be due partly to fact that up to now this form has not been recognized as a species distinct from *C. fugax*; survey work recommended.

Bibliography. Baud (1976), Danielsen *et al.* (1994), Dickinson *et al.* (1991), DuPont (1971, 1972a), Gonzales (1983), Goodman & Gonzales (1990), Goodman *et al.* (1995), Mayr (1938), McGregor (1909-1910), Parkes (1973), Rand (1951), Rand & Rabor (1960), Ripley & Rabor (1958), Siebers (1930).

12. Red-chested Cuckoo

Cuculus solitarius

French: Coucou solitaire German: Einsiedlerkuckuck Spanish: Cuco Solitario

Taxonomy. *Cuculus solitarius* Stephens, 1815, eastern Cape Province. Population on Bioko (Fernando Póo), off Cameroon, sometimes treated as separate race *magnirostris*, on account of larger bill, but shows no other differences and probably does not merit recognition. Monotypic.

Distribution. Senegal through Nigeria to S Sudan and Ethiopia, and S through Zaire, Angola, Zambia, Zimbabwe and Mozambique to S South Africa; Bioko.

Descriptive notes. 31 cm; 75 g. Adult male dark grey above, tail tipped white; chin grey, breast rufous (often dark-barred), upper belly barred black and white, undertail-coverts unbarred whitish; eyelids yellow-green, iris brown, bill black with yellow base, feet yellow. Female often has throat buffy, sometimes pale grey, but never barred; breast usually paler rufous and always barred. Juvenile blackish above with white feather margins, throat to upper breast black with white feather margins, belly barred black and white, tail black with white spots and tip, eye black, bill black, feet orange. Voice. Loud, emphatic 3-note song, dropping in pitch, “piet-my-vrow!” or “IT-will-rain!”; female call a loud “kwik-kwik-kwik-kwik!”. Often sings at night.

Habitat. Forest, open woodland, riparian woodland, thorn scrub, and in montane areas to 3000 m. A forest bird in W, C & S Africa, but more of an open woodland bird in E Africa, where mainly above 1000 m and within 500+ mm rainfall areas; also breeds in semi-arid acacia savanna.

Food and Feeding. Insects, mainly hairy caterpillars, also beetles, grasshoppers, spiders, slugs, centipedes, millipedes, snails; also small frogs and lizards, berries.

Breeding. Breeds in early rains: calls in S Senegal and Gambia in Jun-Aug; breeds Mar-May in E Africa (varies with rains), possibly Apr–Jul in Ethiopia, Oct-Jan in S Africa. Brood-parasitic; hosts mainly thrushes, robins and alethes. Eggs unspotted chocolate-brown in S & E Africa where robin-chats (*Cossypha*) parasitized, blue with fine brown spots for other hosts, especially scrub-robins (*Erythropgyia*) in E Africa; 22 x 18 mm; incubation 12–14 days. Nestling hatches naked, skin dark brown, inside of mouth yellow, darkening to orange, feet yellow; evicts host's eggs and chicks; fledges in 17–21 days.

Movements. Intra-African migrant. Migratory in S part of range, arriving in Malawi and S Africa in Sept and leaving in Mar; perhaps migratory in W Africa, especially Nigeria, where it moves from coastal areas during rains to the N savannas.

Status and Conservation. Not globally threatened. Generally common in forests and woodlands throughout extensive range. Apparently widespread and common in much of E Africa, and a common summer visitor in S Africa. No threats known at present.

Bibliography. Amadon (1953), Archer (1985), Bannerman (1953), Beattie (1981), Benson & Benson (1977), Benson *et al.* (1971), Britton (1980a, 1980b), Cave & Macdonald (1955), Cheke & Walsh (1996), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Desfayes (1975), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire (1996), Elgood, Fry & Dowsett (1973), Elgood, Heigham *et al.* (1994), Friedmann (1930a, 1948a, 1956, 1967), Fry *et al.* (1988), Fuggle (1980), Fuggles-Couchman (1981), Ginn *et al.* (1989), Gore (1990), Grimes (1987), Grobler & Steyn (1980), Hockey *et al.* (1989), Howell *et al.* (1980), Jackson & Sclater (1938), Jensen & Jensen (1969), Lewis & Pomeroy (1989), Lippens & Wille (1976), Liversidge (1955), Mackworth-Præd & Grant (1957, 1962, 1970), Maclean (1993), Maclean & Maclean (1993), Marshall (1984), Mundy (1986), Nikolaus (1987), Oatley (1970, 1980), Penry (1994), Pérez del Val (1996), Pinto (1983), Pitman (1964), Prins (1989), Reed (1969), Rowan (1983), Short *et al.* (1990), Skead (1951), Skinner (1978), Snow (1978), van Someren (1956), Steyn & Myburgh (1980), Wachter *et al.* (1997), Zimmerman *et al.* (1996).

13. Black Cuckoo

Cuculus clamosus

French: Coucou criard German: Schwarzkuckuck Spanish: Cuco Negro

Taxonomy. *Cuculus clamosus* Latham, 1801, Cape of Good Hope = Cradock. Formerly listed as *C. cafer*, but that name was officially suppressed, largely due to confusion with *Clamator leuallantii*. Birds from S Ethiopia to Uganda, W Kenya and NW Tanzania sometimes separated as “*jacksoni*”, but they in fact represent an intermediate or intergrade population. Two subspecies recognized.

Subspecies and Distribution.

C. c. gabonensis Lafresnaye, 1853 - Liberia, Ghana, Nigeria and N Zaire E to S Sudan, Uganda and W Kenya.

C. c. clamosus Latham, 1801 - Ethiopia, E & C Kenya, Tanzania, S Zaire and Angola S to NE Namibia, Zimbabwe and E South Africa; migrates to equatorial W Africa, where recorded irregularly W to Senegambia.

Descriptive notes. 31 cm; 85 g. Adult black above, glossed greenish blue, tail tipped white; iris brown, bill black. Juvenile duller, lacks white tail tip. Races differ in underpart coloration: *clamosus* black below, some with buffish barring (often considered a character typical of females, but extensive examination of specimens does not support this); *gabonensis* has chin to breast rufous with darker bars, remainder of underparts banded black and buff, undertail-coverts often unbarred on male, female with rufous darker, ear-coverts dark (not rufous), breast and belly more heavily barred blackish, often continuing onto undertail-coverts; birds in W Kenya

(“*jacksoni*”) and Uganda are intermediate between *clamosus* and *gabonensis*. Voice. Loud, mournful slow whistle, “whooh whooh whee”, second note shorter and higher, third rising one third of an octave; in aggressive contexts a harsh crescendo “gagagaGAGAGA!”, rising in pitch to a climax, then dropping in pitch and volume; female call “kwik-kwik-kwik-kwik!”. Songs are same throughout species' entire range.

Habitat. Forest, open woodland, riparian woodland, acacia thicket. In S Africa occurs in open woodlands and suburban gardens and avoids evergreen forest and thicket, in E Africa avoids the arid areas, and is a forest bird in C & W Africa. Lowlands, generally below 2000 m.

Food and Feeding. Insectivorous, taking mainly hairy caterpillars, also termites, grasshoppers, beetles; also eats birds' eggs and nestlings.

Breeding. Breeds Oct-Dec in S Africa, Mar-Apr in Tanzania; few breeding records C & W Africa, none W of Cameroon, and unknown whether black forms in W Africa breed there. Brood-parasitic; hosts mainly bush-shrikes, e.g. Boubou Shrike (*Laniarius aethiopicus*), Crimson-breasted Shrike (*L. atrococcineus*) in S Africa. Female lays up to 22 eggs in a season. Eggs whitish or pale green with reddish brown marks, similar to eggs of boubous; 25 x 19 mm; incubation 14 days. Nestling hatches naked, pale brownish pink skin (darkens to purplish black), inside of mouth pink; fledges in 20–21 days.

Movements. Race *gabonensis* is sedentary in forests in W & C Africa. Race *clamosus* is migratory in S Africa, where it sings and is present mainly Sept-Dec but also remains until Mar; migrates to equatorial and W Africa N of the forest zone, where may breed irregularly; present mainly Mar-Nov in Sierra Leone, where race *gabonensis* unknown; occurs in all months locally in E Africa.

Status and Conservation. Not globally threatened. Generally common resident in forests in lower Guinea region of W Africa and equatorial C & E Africa; common breeding visitor in areas of open woodland in S Africa. Often overlooked when present and not breeding, e.g. in NW Zambia in Sept.

Bibliography. Bannerman (1953), Benson & Benson (1977), Benson *et al.* (1971), Britton (1980a), Brown & Britton (1980), Cave & Macdonald (1955), Chapin (1939), Cheke & Walsh (1996), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire (1996), Elgood, Fry & Dowsett (1973), Elgood, Heigham *et al.* (1994), Friedmann (1930a, 1948a, 1956, 1966, 1967), Fry *et al.* (1988), Ginn *et al.* (1989), Grimes (1987), Hockey *et al.* (1989), Jensen & Clinning (1974), Jensen & Jensen (1969), Lewis & Pomeroy (1989), Lippens & Wille (1976), Lockhart (1996), Louette & Herroelen (1993), Mackworth-Præd & Grant (1957, 1962, 1970), Maclean (1993), Markus (1965), Payne (1973, 1974), Penry (1976, 1994), Pinto (1983), Pryce (1989), Rowan (1983), Short *et al.* (1990), Skead (1951), Snow (1978), Sweet (1994), Zimmerman *et al.* (1996).

14. Indian Cuckoo

Cuculus micropterus

French: Coucou à ailes courtes German: Kurzflügelkuckuck Spanish: Cuco Alicorto

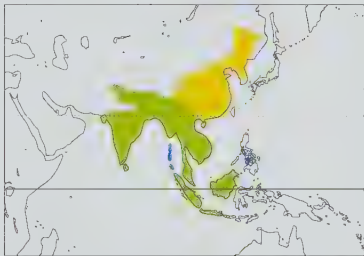

Other common names: Short-winged Cuckoo

Taxonomy. *Cuculus micropterus* Gould, 1837, Himalayas. Two subspecies recognized.

Subspecies and Distribution.

C. m. micropterus Gould, 1837 - Kashmir and Himalayan foothills S through India to Sri Lanka, and E through Nepal, Bangladesh, Myanmar and Thailand to E China, Mongolia, Korea and Russian Far East; winters S to Andaman and Nicobar Is, Peninsular Malaysia, Sumatra, Java, Borneo and Philippines.

C. m. concretus S. Müller, 1845 - Vietnam, S Thailand, Peninsular Malaysia, Sumatra, Java and Borneo.

Descriptive notes. 32–33 cm; 119 g. Adult male dark slate-grey above, back tinged brownish, tail barred white at sides and with broad black subterminal band; pale ashy and white below with widely spaced black bands; eye-ring grey to yellow, iris brown, bill black above, greenish with yellow base below, feet yellow. Female with throat pale grey and breast brownish. Juvenile broadly tipped with rufous and white above, head and neck broadly barred white, tail more rufous; black-barred buff below. Race *concretus* smaller. Voice. Loud, flute-like, hollow 4-note whistle, final note lower-pitched, “orange-pekoee” or “crossword puzzle”.

Habitat. Deciduous and evergreen forests, second growth, dry country. Lowlands to hills at 2000 m, sometimes to 2800 m; in Nepal to 2100 m, occasionally higher, to 3700 m.

Food and Feeding. Insects, mainly hairy caterpillars, also butterflies, grasshoppers, ants; fruit. Forages in high canopy, but sometimes feeds on ground.

Breeding. Calls May-Jul in India, Jan-May in Sri Lanka, Jan-Aug in Malaysia. Brood-parasitic; hosts in India drongos, e.g. Black Drongo (*Dicrurus macrocercus*) and Grey Drongo (*D. leucophaeus*); in China *D. macrocercus* and Azure-winged Magpie (*Cyanopica cyanea*); in Russia Brown Shrike (*Lanius cristatus*); in Malaysia fledglings (not definitely of this species) fed by Black-and-yellow Broadbills (*Eurylaimus ochromalus*); in Java Greater Racquet-tailed Drongo (*D. paradiseus*). Eggs whitish with reddish brown markings, 25 x 19 mm (Lower Amur); blue eggs in India suspected to be from this cuckoo; incubation 12 days (14 days with shrikes). Nestling naked at hatching, 4–7–4–9 g, skin yellowish pink, gape flange yellow, mouth-lining orange-red; begging call resembles that of host's nestlings.

Movements. Resident in S part of range. Summer visitor in N of range and in most of temperate Asia; passage migrant in Korea, possibly breeding in places where remains and sings in Jun; migrates to winter in tropical S Asia, including Andaman Is and Greater Sundas, also Philippines. Apparently only accidental in Japan and also in NE Pakistan.

Status and Conservation. Not globally threatened. Fairly common throughout year in Thailand; widespread in Myanmar, where it appears to be more numerous in the higher hills. Uncommon in Sumatra and Borneo, and rare in Java; uncommon in dry country in Sri Lanka, where occurs mainly in winter, but also sings and may breed. In the Philippines, rare on migration and in winter. Also recorded on Bangka, and one record from N Moluccas, on Ternate.

15. Common Cuckoo

Cuculus canorus

French: Coucou gris

German: Kuckuck

Spanish: Cuco Común

Other common names: (Grey/European/Eurasian) Cuckoo

Taxonomy. *Cuculus canorus* Linnaeus, 1758, Sweden.

Forms a superspecies with *C. gularis*, with which formerly considered conspecific. Populations of C Asia (Russian Altai and E Sinkiang through Mongolia to N & C China) sometimes separated subspecifically as *telephonus* on the basis of size (smaller than *subtelephonus*) and pale plumage (like *subtelephonus*), but birds in this area are not constant in these characters and overlap with other races occurs; range limits of nominate and race *subtelephonus* in C Asia rather unclear. Four subspecies currently recognized.

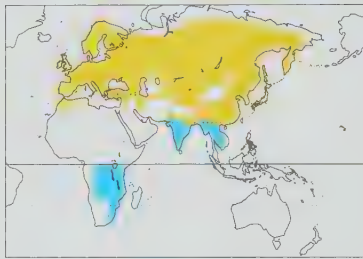

Subspecies and Distribution.

C. c. bangsi Oberholser, 1919 - Iberian Peninsula, Balearic Is, Morocco, Algeria and Tunisia; winters in Africa.

C. c. canorus Linnaeus, 1758 - British Is and Scandinavia E through N Russia and Siberia to Kamchatka and Japan, and S to Pyrenees and Mediterranean, Asia Minor and N Iran, Turkmenia, Kazakhstan, Mongolia, N China and Korea; winters in Africa and S Asia.

C. c. subtelephonus Zarudny, 1914 - C Asia from Turkestan to W Ala Shan in S Mongolia; winters in S Asia and Africa.

C. c. bakeri Hartert, 1912 - W China (W Sichuan) to Himalayan foothills in N India, Nepal, Khasi Hills, Myanmar (including Shan States), NW Thailand and S China; winters to Assam, E Bengal and SE Asia.

Descriptive notes. 32-33 cm; 115 g. Adult male dark ashy-grey above; tail blackish brown, spotted and tipped with white, unevenly barred black; chin to breast ashy-grey, rest of underparts white with black bars; eye-ring yellow, iris light brown to orange, bill black with yellow base, feet yellow. Female similar, but with rufous tinge on upper breast; female (race *canorus* only) also occurs in a rufous ("hepatic") morph, with upperparts barred chestnut and blackish brown, rump and uppertail-coverts plain rufous, underparts white barred pale chestnut and blackish, lower breast tinged rufous. Juvenile has white nape spot, white tips to crown and back

feathers. Race *subtelephonus* pale, black bars below narrow; *bakeri* darker grey than *canorus*; *bangsi* smaller, females often with much rufous on breast. **Voice.** Male song a loud burry "cuck-oo", first note higher and louder; female a bubbling "kwik-kwik-kwik!". Silent on winter grounds in Africa, but occasionally sings when on spring migration in coastal E Africa.

Habitat. Forests and woodlands, both coniferous and deciduous, second growth, open wooded areas, wooded steppe, scrub, heathland, also meadows, reedbeds. Lowlands and moorlands and hill country to 2000 m, in Nepal to 3800 m.

Food and Feeding. Insects, mainly caterpillars, less often dragonflies, damselflies, mayflies, crickets, cicadas; beetles in cold weather upon spring arrival on N breeding grounds; also spiders, snails, rarely fruit. Preys on eggs and nestlings of small birds. Female may forage 2-3 km from laying sites; male feeds at up to 4 km from singing site.

Breeding. Season May-Jun in UK and elsewhere in NW Europe, Apr-May in Algeria, Apr-Jul in India and Myanmar. Brood-parasitic: hosts include many insectivorous songbird species (over 100 have been recorded), e.g. flycatchers, chats, warblers, pipits, wagtails and buntings; some species only occasionally parasitized, but still raise young cuckoo. Often mobbed by real or potential hosts near their nests. Eggs polymorphic in colour (blue, pink, whitish) and pattern (spotted or unmarked) in Palearctic, where 15 distinct types recognized, and c. 77% of eggs closely match those of host in colour and pattern; eggs also polymorphic in E India, where mimic eggs of several host species; 23 x 17 mm; incubation 11-5-12-5 days. Nestling period 17-18 days; evicts host's eggs and chicks; fledges at 80 g, then fed by foster parents for another 2-3 weeks.

Movements. Migratory in N of range, arriving in SW Britain mainly Apr-May, when occasionally recorded in small parties, and even in one flock of 50+ birds; also seasonal in hill country from Assam and Chin Hills to Shan States, where present Mar-Aug. Resident in tropical lowland areas of S Asia. Winter resident in sub-Saharan Africa and in Sri Lanka. W Palearctic populations migrate to Africa, where a Dutch-ringed juvenile found in Togo in Oct and a British-ringed juvenile found in Cameroon in Jan; migrants appear in N Senegal as early as late Jul through Oct; in W Africa nearly all records are in autumn (Sept-Dec), birds apparently continuing on to C & S Africa. Race *bangsi* occurs on passage in W Africa, and winters S of equator from W Africa to L Tanganyika. Asian populations of nominate *canorus* and *bakeri* winter in India, SE Asia and Philippines, also in Africa, but the extent of migration of Asian birds to Africa is unknown; some *subtelephonus* migrate through Middle East and occur in winter from Uganda and E Zaïre to Zimbabwe, Mozambique and Natal. Mainly a passage migrant in Middle East, though some breed in region. Migrants also appear on islands in W Indian Ocean (Seychelles, Aldabra). Nominative *canorus* accidental in Iceland, Faeroes, Azores, Madeira, Canary Is and Cape Verde Is, rarely also Alaska and eastern N America; one record of *canorus* in Indonesia, off W Java in winter.

Status and Conservation. Not globally threatened. Generally a common and vocally conspicuous species throughout its range. Densities include 1-2 males/km² in suitable habitats in N Europe. Population of Britain and Ireland estimated at 16,000-32,000 pairs, and that of France at 100,000-1,000,000 pairs. Numbers have been decreasing in W Europe during 20th century.

Bibliography. 16. African Cuckoo

Cuculus gularis

French: Coucou africain

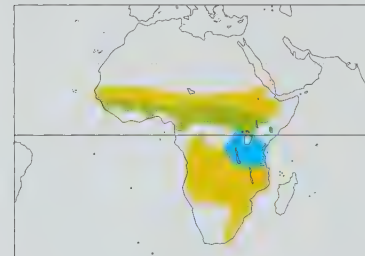

German: Afrikanerkuckuck

Spanish: Cuco Barbablanca

Taxonomy. *Cuculus gularis* Stephens, 1815, Camdeboo, Cape Province.

Forms a superspecies with *C. canorus*, with which formerly considered conspecific. Monotypic.

Distribution. Senegal and Gambia through N Nigeria to Eritrea, NW Somalia and Kenya, and S to Namibia, Botswana, Zimbabwe and E South Africa (Transvaal and Natal).

Descriptive notes. 32 cm; 110 g. Adult dark ashy-grey above; tail dark grey with blackish barring, white tip, outer feathers barred white; chin to breast ashy-grey, rest of underparts white with narrow black bars which tend to fade out on lower belly; eye-ring yellow, iris yellow, bill yellow with black tip. Female sometimes slightly barred or rufous on throat or breast; no rufous morph. Juvenile greyer (not brown) than *C. canorus*, broader white spots in tail. **Voice.** Male song a loud burry "coo-coo", second note slightly higher and louder; female a bubbling "kwik-kwik-kwik!".

Habitat. Open woodland, acacia savanna;

avoids dense evergreen forest and arid regions.

Food and Feeding. Insects, mainly caterpillars. Forages through foliage, and also takes food on ground.

Breeding. Breeds in rains, Jan-Jun in coastal Ghana, Feb-Apr in Nigeria, Aug-Nov in Kenya, Sept-Dec in S Africa. Brood-parasitic: hosts in Senegal, Ghana, Togo and Nigeria include Fork-tailed Drongo (*Dicrurus adsimilis*) and Yellow-billed Shrike (*Corvinella corvina*), perhaps occasionally other species. Eggs whitish with pale brown spots or rufous blotches, similar to drongo eggs; 25 x 18 mm. Nestling evicts host's eggs and young; fledges in 20-23 days.

Movements. Intra-African migrant. Arrives with the rains, sings and breeds during rainy season, then disappears; no ringing recoveries to show details of seasonal dispersal. In Malawi, arrives Oct and departs by Apr; in Kenya, appears with the rains, present mainly Oct-May, but breeds by Aug; in Ghana and Togo, observed Jan-Aug or Sept, rarely Oct and Nov; in Nigeria and Gambia, observed in all seasons, though not throughout this period in any one locality.

Status and Conservation. Not globally threatened. Fairly common in general throughout its sizeable range, though no precise figures available; locally common in some parts, notably in S Africa, but rather uncommon in E Africa.

Bibliography. Bannerman (1953), Benson & Benson (1977), Benson *et al.* (1971), Britton (1980a), Cheke & Walsh (1996), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood, Fry & Dowsett (1973), Elgood, Heigham *et al.* (1994), Evans & Balmford (1992), Friedmann (1956, 1967), Fry *et al.* (1988), Ginn *et al.* (1989), Gore (1990), Grimes (1979, 1987), Jackson & Sclater (1938), Jensen & Jensen (1969), Lamarche (1980), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1957, 1962, 1970), Maclean (1993), Morel & Chappuis (1992), Nikolaus (1987), Ottow & Duve (1965), Payne (1977a, 1986), Penry (1994), Pinto (1983), Rowan (1983), Short *et al.* (1990), Snow (1978), Tarboton (1975, 1986), Wachter *et al.* (1997), Zimmerman *et al.* (1996).

17. Himalayan Cuckoo

Cuculus saturatus

French: Coucou oriental

German: Hopfkuckuck

Spanish: Cuco Oriental

Other common names: Oriental Cuckoo (with *C. horsfieldi*); Blyth's Cuckoo, Southern Muted Cuckoo

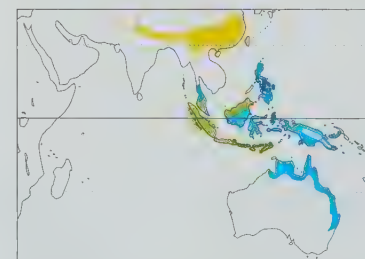

Taxonomy. *Cuculus saturatus* Blyth, 1843, Nepal.

Often regarded as conspecific with *C. horsfieldi*, but the songs of the two are distinct (see page 512). Bornean population formerly recognized as a distinct subspecies, *insulindeae*, but does not differ from *lepidus* of Malaysia, Sumatra and Java. Race *lepidus*, including Bornean birds, has been included in *C. poliocephalus*, but on present evidence more appropriately placed in present species. Two subspecies currently recognized.

Subspecies and Distribution.

C. s. saturatus Blyth, 1843 - Kashmir through S Himalayas, Assam, N & E Myanmar (including Shan States) and Thailand to S China and Taiwan; winters from Malaysia and Philippines S to Lesser Sundaes, New Guinea and Australia.

C. s. lepidus S. Müller, 1845 - Peninsular Malaysia, Sumatra (and satellite islands), Borneo, Java, Bali and Lesser Sundaes (Lombok, Sumbawa, Flores, Pantar, Sumba, Timor).

Descriptive notes. 29 cm; 90-6 g. Adult male dark ashy-grey above, tail blackish brown, spotted and tipped with white; chin to breast ashy-grey, lower breast and abdomen white with black bars, vent white to creamy apricot with barring somewhat variable; eye-ring yellow, iris yellow to brown, bill black with yellow base, feet yellow. Female similar, with rufous tinge to breast; also occurs in a rufous morph, in which rump and uppertail-coverts rufous with dark barring (like *C. horsfieldi*, but unlike *C. canorus* and *C. poliocephalus*). Juvenile slate-grey above with white feather edges, throat black with white bars, below

barred black and white, iris brown; two plumage morphs in both sexes. Differs from very similar *C. canorus* in black bars below usually being broader and more widely spaced, and bend of wing

below unbarred (barred brown and white in *C. canorus*); also, rufous morphs have rump and uppertail-coverts barred dark (plain rufous in *C. canorus*). Race *lepidus* significantly smaller. Voice. Song a high note followed by 3 lower flat notes, "hoop, hoop-hoop" or "tun-tadun"; female call "quick-quick-quick". Silent in non-breeding range.

Habitat. Forest canopy, open wooded areas and orchards, often in hill country, also in coniferous forest and in birch (*Betula*) above tree-line. Occurs at all altitudes in Java and Sumatra; a montane species in Borneo, mostly at 1300-2700 m, and in Himalayas at 1500-3300 m.

Food and Feeding. Insects, mainly caterpillars (hairless and hairy: Arctiidae, Lasiocampidae, Sphingidae, Saturniidae, Noctuidae), grasshoppers, crickets, beetles, also ants; some fruit.

Breeding. Breeds during nesting season of small warblers: May-June in Kashmir, May in Fujian, Feb-Jul in Malay Peninsula, Jul in Java and Borneo. Brood-parasitic: hosts mainly small warblers of genera *Phylloscopus* and *Seicercus*, e.g. Large Crowned Warbler (*P. occipitalis*) in Kashmir, Crowned Leaf-warbler (*P. reguloides*) in Himalayas and Assam, Mountain Leaf-warbler (*P. trivirgatus*) in Borneo, Chestnut-crowned Warbler (*S. castaneiceps*) in Malaysia, Sunda Warbler (*S. grammiceps*) in Java. Eggs variable, oviduct eggs pale blue or white with fine black and brown or reddish stippling; 21 x 16 mm.

Movements. Race *lepidus* is resident. Nominate *saturatus* is a summer visitor to its breeding areas, being present for example in Kashmir from late Apr to Aug and in Nepal in Mar-Sept; it winters in the Malay Peninsula and Philippines and S through Sumatra, Java, Borneo, Sulawesi, Moluccas, Lesser Sunda and New Guinea, to the coastal parts of N & E Australia.

Status and Conservation. Not globally threatened. Numbers depend on maintaining forest habitats for populations of the host species. Present species is common in mountains in Borneo, where both resident *lepidus* and non-breeding *saturatus* are said to be present in equal numbers; *lepidus* is uncommon in Sumatra and Java, but common at hill stations in Peninsular Malaysia. Few data are available on nominate *saturatus*, which appears to be only a scarce winter visitor to the lowlands of Malaysia; status in Thailand uncertain, but species is uncommon and may well be mainly a passage migrant.

Bibliography. 18. Horsfield's Cuckoo

Cuculus horsfieldi

French: Coucou asiatique **German:** Horsfeldkuckuck **Spanish:** Cuco de Horsfield
Other common names: Oriental Cuckoo (with *C. saturatus*); Northern Muted Cuckoo

Taxonomy. *Cuculus horsfieldi* F. Moore, 1857, Java.

Often regarded as a subspecies of *C. saturatus*, but the songs of the two are distinct (see page 512). Monotypic.

Distribution. European Russia E through Siberia to Kamchatka, S to Kazakhstan, the Altai, Mongolia and N China, Korea and Japan. Winters from SE Asia to Australia.

Descriptive notes. 30-33 cm; 99 g. Adults virtually identical to *C. saturatus*, but larger: eye-rings yellow, iris yellow to brown, bill black, greenish to yellow at base and cutting edge, feet yellow. Differs from *C. canorus* in having bend of wing below unbarred white, and often wider and sparser black bars below (especially in C Asia, where race *subtelephonus* of *C. canorus* has narrow bars); rufous morph female has rump and uppertail-coverts barred dark (plain rufous in *C. canorus*). Juvenile, as in *C. saturatus*, often more broadly barred black below than juvenile *C. c. canorus*, but some are dark grey on throat and upper breast, with lower breast and

belly almost unbarred white. Voice. Song 4 low "hoop" whistles, the first one soft; also a harsh call, "gaak-gaak-gak-ak-ak".

Habitat. Forests, especially coniferous and mixed-coniferous, e.g. with birch (*Betula*) and aspen (*Populus*); sometimes broadleaf forests and thickets, as in Japan. In Sichuan to 4500 m; in Altai at lower altitudes than *C. canorus*, rarely above 1000 m.

Food and Feeding. Insects, mainly hairy caterpillars, also beetles, hymenoptera, flies.

Breeding. Brood-parasitic: hosts include Chiffchaff (*Phylloscopus collybita*) and other *Phylloscopus* warblers, e.g. Large Crowned Warbler (*P. occipitalis*), and also Olive-backed Pipit (*Anthus hodgsoni*) in Russia; Bush Warbler (*Cettia diphone*) in N Japan; *P. occipitalis* and other small songbirds elsewhere in Japan. Eggs brown in N Japan, whitish with brown markings elsewhere in Japan; 22 x 15.7 mm. Nestling naked at hatching, orange gape, black gape flanges; evicts host's eggs and young.

Movements. Migratory. Winters in Malaysia, Sumatra, Java, Borneo, Philippines, Moluccas, S to New Guinea and N & E Australia; straggler to New Zealand, Bering Sea islands and W Alaska, also W Europe.

Status and Conservation. Not globally threatened. Species is common or frequent in its W Palearctic range and in NE Asia. Owing to difficulties of identification, the relative abundance of *C. saturatus* and present species in their non-breeding ranges, in Indonesia, New Guinea and Australia, remains essentially unknown.

Bibliography. Ali & Ripley (1981), Becking (1975), Brazil (1991), Cheng Tsohsin (1987), Coates (1985), Cramp (1985), Dementiev & Gladkov (1951a), Dickinson *et al.* (1991), Ernst (1992a, 1992b), Échécopar & Hùe (1978), Fiebig (1993), Flint *et al.* (1984), Gore & Pyong-Oh (1971), Grant (1964), Higuchi (1986, 1989), Higuchi & Payne (1986), Knyshtaus (1993), MacKinnon & Phillips (1993), van Marle & Voous (1988), Mauersberger (1980), Parkes (1990b), Rand & Gilliard (1967), Reed (1972), Ripley (1982), Rogacheva (1992), Smythies (1981), Stepanyan (1990a), Tomek (1985), Vaurie (1965), Wells (1972a), White & Bruce (1986).

19. Asian Lesser Cuckoo

Cuculus poliocephalus

French: Petit Coucou **German:** Gackelkuckuck **Spanish:** Cuco Chico
Other common names: Lesser/Small/Little Cuckoo

Taxonomy. *Cuculus poliocephalus* Latham, 1790, India.

Forms a superspecies with *C. rochii*, the two sometimes being treated as conspecific. Race *C. saturatus lepidus* has been placed in present species, but present evidence does not support that treatment. Monotypic.

Distribution. N Afghanistan, N Pakistan and Kashmir E through Himalayan foothills to Khasi and Naga Hills, Bangladesh and N Myanmar, and across China to Ussuriland, Korea and Japan; winters in peninsular India, Sri Lanka and E Africa.

Descriptive notes. 25 cm; 52 g. Adult male slate-grey above, tail and uppertail-coverts contrastingly blackish, tail with white tip and white spots at sides; bend of wing below unbarred white; throat and breast light grey, belly white with black bars, undertail-coverts often also barred black; eye-ring yellow, iris dark brown, bill black with yellow base, feet tan-yellow. Female similar, sometimes with breast washed rufous; also occurs in rufous morph, with head and upperparts rufous, back and wings barred rufous and black, rump and uppertail-coverts plain rufous. Juvenile slate-grey with white bars above, face black with white bars, breast and belly barred black

and white; rufous morph barred tawny above, barred brown and buff below. Voice. Loud, husky chattering song, "eat your choko pepper", 6 notes at 1.5-2.5 kHz, rising and falling in pitch.

Habitat. Forests, both broadleaf and pine, scrub, second growth; in Ussuri Territory in broadleaf forests of birches (*Betula*), hornbeams (*Carpinus*), maples (*Acer*) and oaks (*Quercus*). Mostly between 1500 m and 3660 m in Himalayas; in Japan usually to 1200 m, sometimes to 2300 m. In non-breeding season in India, this is only cuckoo noted in pine forest plantations, similar to its habitat in breeding area in India.

Food and Feeding. Insects, mainly caterpillars (geometrids, noctuids), also beetles, hymenoptera, mantids.

Breeding. Breeds May-Jul. Brood-parasitic: hosts small warblers, wren-babblers (*Pnoepyga*) and shortwings (*Brachypteryx*) in India, Japanese Bush-warbler (*Cettia diphone*) and other small songbirds in Korea and Japan. Eggs in Japan unmarked brown. 21 x 16 mm; in India, similar unmarked brown eggs from oviduct of laying females resemble cuckoo eggs found in nests of *Niltava* flycatchers; other eggs from laying females in India are unmarked white, resembling cuckoo eggs from nests of Large Crowned Warbler (*Phylloscopus occipitalis*).

Movements. Migratory, entire breeding population apparently moving SW or S to wintering grounds. Winters in peninsular India, Sri Lanka and also in E Africa; occurs in Seychelles on autumn (Nov) and spring (Apr) passage. Almost unknown in Thailand, where only three specimens known (all from N in May). Present in Kenya Nov-April: one ringed in coastal Kenya in Nov recovered inland in Kenya in Dec; birds in Apr clearly departing migrants, as they are fat and silent.

Status and Conservation. Not globally threatened. Few data on abundance; common to fairly common locally in Nepal. Populations depend on maintaining habitat and numbers of its host species. Not uncommon in winter in E Africa, but considered rare in winter in Sri Lanka.

Bibliography. Ali & Ripley (1981), Ali *et al.* (1996), Bates & Lowther (1952), Becking (1981, 1988), Benson (1951), Benson & Benson (1977), Benson *et al.* (1971), Brazil (1991), Britton (1980a), Cheng Tsohsin (1987), Dementiev & Gladkov (1951a), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Échécopar & Hùe (1978), Fiebig (1993), Flint *et al.* (1984), Friedmann (1956), Fry *et al.* (1988), Fujimaki (1992), Gore & Pyong-Oh (1971), Higuchi (1986, 1989), Higuchi & Payne (1986), Higuchi & Sato (1984), Knyshtaus (1993), Legge (1880), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1957, 1962), Maclean (1993), Madoc (1976), Moreau (1972), Nechaev (1972), Osmaston (1916), Phillips (1978), Ripley (1982), Roberts, T.J. (1991), Short *et al.* (1990), Smythies (1986), Stepanyan (1990a, 1995), Wells (1972a), Wells & Becking (1975), Zimmerman *et al.* (1996).

20. Madagascar Lesser Cuckoo

Cuculus rochii

French: Coucou de Madagascar **German:** Madagaskarkuckuck **Spanish:** Cuco Malgache
Other common names: Madagascar Cuckoo

Taxonomy. *Cuculus rochii* Hartlaub, 1863, Tamatave, Madagascar.

Forms a superspecies with *C. poliocephalus*, of which sometimes considered a race. Monotypic.

Distribution. Madagascar. Migrates to E Africa.

Descriptive notes. 26 cm; 64 g. Adult, sexes alike, rufous morph unknown; slate-grey above, tail and uppertail-coverts black, tail with white tip and white spots at sides; bend of wing below grey-barred white; throat and breast light grey, belly white with black bars, undertail-coverts usually unbarred; eye-ring yellow, bill black with yellow base, broader at base than in *C. poliocephalus*, feet yellow. Female as male, no rufous morph. Juvenile resembles juvenile *C. poliocephalus*, some with rufous spots or bars in wing. Voice. Four evenly spaced notes, "ho-ho-ho-hu", first three higher and fourth lower, the whole song lower in pitch than that of *C.*

poliocephalus.

Habitat. Forest, including introduced eucalyptus plantations, gallery forest, scrub woodland spiny subdesert woodland and marshes; recorded in various altered habitats. Sea-level to 1800 m.

Food and Feeding. Insects, e.g. hairy caterpillars.

Breeding. Breeding season Oct-Apr (egg records). Brood-parasitic: hosts Madagascar Cisticola (*Cisticola cherina*); 10 of c. 210 clutches were parasitized, also Common Jery (*Neomixis tenella*); 1 of c. 50 clutches, Madagascar Paradise Flycatcher (*Terpsiphone mutata*); 1 of 8 clutches and Madagascar Sunbird (*Nectarinia souimanga*). Eggs whitish, often tinged pink, spotted with reddish brown, do not closely match eggs of host species; c. 18 x 14 mm.

Movements. Migratory. Most of the population moves in non-breeding season from Madagascar NW to Africa, where occurs in Apr-Sept from E Zaire and Kenya to Zambia, Malawi and Mozambique. Arrives and sings in Madagascar in Sept-Nov, somewhat later in the dry SW. Within Madagascar, migrates in rainy season from forested E to dry W of country. Occasional in Mauritius.

Status and Conservation. Not globally threatened. No precise data on abundance from breeding range in Madagascar, but commonly heard in wide range of habitats, from E rain forest to spiny subdesert woodland, and probably common to very common. Species appears to be at best uncommon in African non-breeding quarters, but is little known and quite possibly overlooked.

Bibliography. Albiguac (1970), Appert (1996), Becking (1988), Benson (1974), Benson & Benson (1977), Benson, Brooke *et al.* (1971), Benson, Colebrook-Robjent & Williams (1976-1977), Berlioz (1948), Britton (1980a), Dee (1986), Delacour (1930, 1932a), Dowsett & Dowsett-Lemaire (1980, 1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Langrand (1990), Lewis & Pomeroy (1989), Louette & Herroelen (1993), Mackworth-Præd & Grant (1957, 1962), Maclean (1993), Milon (1959), Milon *et al.* (1973), Rand (1936), Salvan (1970), Short *et al.* (1990), van Someren (1947), Wilmé (1994), Wilmé *et al.* (1997), Zimmerman *et al.* (1996).

21. Pallid Cuckoo

Cuculus pallidus

French: Coucou pâle

German: Blaßkuckuck

Spanish: Cuco Pálido

Taxonomy. *Columba pallida* Latham, 1801, New South Wales.

Considered by some authorities to be intermediate in form between genera *Cuculus* and *Cacomantis*. Monotypic.

Distribution. Australia and Tasmania. Winters N to Wallacea.

Descriptive notes. 31-32 cm; 82 g. Adult grey above, broad pale supercilium, darker grey line through eye, pale nape patch, outer tail barred white; pale grey below, not barred; eye-ring yellow, iris dark brown, bill black, feet grey. Some birds (subadults?) are mottled brown and rufous above, with breast barred black and rufous. Juvenile white with black streaks above, throat and breast blackish, lower breast and belly white with dark grey streaks. **VOICE.** Male's song an 8-note whistle on ascending scale (second note lower); female a hoarse whistle.

Habitat. Open forests, woodlands, scrub, spinifex plains, mangroves, gardens; most numerous in drier country. Found in the most interior parts of Australia more commonly than any other cuckoo.

Food and Feeding. Insects, mainly grasshoppers, beetles, caterpillars and other larvae. Food taken in trees or on the ground.

Breeding. Breeds Mar-Jun and Sept in N, Aug-Oct in SW Western Australia, Sept-Dec in E Australia. Adult male courtship-feeds female. Brood-parasitic: hosts mainly honeyeaters (Meliphagidae) with open nests, also shrike-thrushes (*Colluricincla*), cuckoo-shrikes (*Coracina*) and others: 21 of 32 known hosts are honeyeaters. Eggs pink, unspotted or with brown specks around large end; 25 x 16 mm;

incubation 12-14 days. Young evicts host's eggs and chicks; fed by hosts as long as 6 weeks after fledging, and sometimes fed by neighbouring birds as well as by hosts themselves. Adult of present species once seen feeding a fledged young attended by its hosts.

Movements. Resident, migratory, or with erratic movements in most of Australia, where many birds overwinter. In N Australia occurs in all months, but little breeding; in drier parts of Australia mainly a wet-season visitor. In SW Western Australia, adults arrive Jun and depart Nov; juveniles may remain with foster parents until Feb. Migratory movements are seen along

coastal E Australia, in the Murray-Darling region, and at Murphy's Creek. Non-breeding birds occur during the austral winter in the Moluccas and Lesser Sundas (Flores, Timor), and occasionally in New Guinea. Movements and the distribution of wintering birds through Australia N of 20°S, the reporting rates in summer and winter N of South Australia, and the limited range of cuckoos elsewhere suggest that most birds remain in Australia and move within the continent. In Tasmania, occurs only in the breeding season.

Status and Conservation. Not globally threatened. Widespread and common, at least locally, though some variation in numbers. This species seems reasonably adaptable, since it occurs in residential and suburban areas where honeyeater hosts are attracted to flowering gardens, as well as in less inhabited areas of scrub and open woodland.

Bibliography. Beruldsen (1980), Blakers *et al.* (1984), Brooker & Brooker (1989a), Coates (1985), Coates & Bishop (1997), Cooper (1958), Disney (1977), Hall (1974), Hardy & Hardy (1973), Hobbs (1990), Kikkawa & Dwyer (1962), Klapste (1981), Lindsey, T.R. (1992), Macdonald (1988), Marchant (1989), Mayr (1964), Noske (1981), Pizzey & Doyle (1980), Rand & Gilliard (1967), Rose (1997a), Schodde & Tidemann (1986), Simpson & Day (1996), Smith (1989), Storr (1977, 1980, 1984b, 1991), Strahan (1994), Stresemann, E. & Stresemann (1966), Stresemann, V. & Stresemann (1961), Stronoch (1981), Trounson & Trounson (1987), Watts (1993), White & Bruce (1986), Woodell *et al.* (1985).

Genus *CERCOCOCCYX* Cabanis, 1882

22. Dusky Long-tailed Cuckoo

Cercococcyx mehowi

French: Coucou de Mechow **German:** Schweifkuckuck **Spanish:** Cuco Colilargo Oscuro

Taxonomy. *Cercococcyx mehowi* Cabanis, 1882, Angola. Monotypic.

Distribution. Sierra Leone, Guinea, Liberia and Ivory Coast through Nigeria, Cameroon, Gabon and Congo to E Zaire, Uganda and NW Tanzania, and S to C Zaire and extreme NW Angola.

Descriptive notes. 31-34 cm; 55 g. Adult dark grey above, flight-feathers barred rufous, tail long, rectrices broad, tipped white or pale rufous; wing about 75% of tail length; black barring below, belly unmarked reddish buff; iris brown, eyelids yellow, bill greenish black, lower mandible greenish, mouth yellow, legs and feet yellow. Juvenile has rufous edges to crown, neck and breast feathers, variably rufous-barred upperparts, rectrices pointed. **Voice.** (1) Whistle of 3 emphatic notes, "tu-tu-to", on same or slightly rising pitch, accent on second note, the series repeated after 1-sec pause; rate of 17 songs/40 sec. (2) Whistle of c. 30 syllables and 10-sec

duration, "teu, tew, du du du...", slightly falling in pitch, slowing near end. Silent in non-breeding season.

Habitat. Lowland mature forest, especially lower levels and dense undergrowth, often near water-courses.

Food and Feeding. Insects, especially caterpillars, most hairy; also beetles, ants, spiders, small snails and seeds.

Breeding. Breeds during rains; calls Apr-Dec near Kagoro, Nigeria; gonads enlarged Dec-Feb in Cameroon; apparent laying Nov and Jan in NE Gabon. Brood-parasitic: hosts not well known, but fledgling fed by Brown Illadopsis (*Trichastoma fulvescens*); also, adult perched on nest of Blue-headed Monarch-flycatcher (*Trochocercus nitens*) as it apparently laid. Forest robin (*Stiphrornis erythrothorax*) suspected as host, with two observations of unspotted, brownish cuckoo eggs in nest; hatchling cuckoo ejected young robin, and partly developed plumage of juvenile *C. mehowi*.

Movements. Resident. Extent of seasonal wandering unknown.

Status and Conservation. Not globally threatened. In general, not reckoned to be rare, though apparently uncommon in Nigeria; not uncommon in Sierra Leone. This is an elusive species, difficult to see, so size of population is difficult to gauge.

Bibliography. Ash (1990), Baker & Baker (1994), Bannerman (1953), Benson (1964), Britton (1980a), Brosset & Énard (1986), Chapin (1928, 1939), Cheke & Walsh (1996), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Dowsett & Forbes-Watson (1993), Dyer *et al.* (1986), Elgood *et al.* (1994), Friedmann (1966), Fry *et al.* (1988), Grimes (1987), Lippens & Wille (1976), Louette (1981), Louette & Herroelen (1994), Mackworth-Praed & Grant (1957, 1962, 1970), Pinto (1983), Ripley & Heinrich (1966a), Short *et al.* (1990), Snow (1978).

23. Olive Long-tailed Cuckoo

Cercococcyx olivinus

French: Coucou olivâtre **German:** Olivkuckuck **Spanish:** Cuco Colilargo Oliváceo

Taxonomy. *Cercococcyx olivinus*, Sassi, 1912, forest on mountains bordering Rutshuru Plain, Zaire. Forms a superspecies with *C. montanus*. Monotypic.

Distribution. Guinea and Ghana through S Nigeria and Cameroon to N Congo, N Zaire, W Uganda, Kasai zone (NE Angola, SW Zaire), NW Angola and NW Zambia; possibly also Sierra Leone, with two recent records from Gola Forest.

Descriptive notes. 32-34 cm; 65 g. Adult dark olive-brown above, crown greyish, remiges and coverts often unbarred, tail long, rectrices broad, tipped white or pale rufous; wing about 82% of tail length; whitish below, with black barring; iris dark brown, eye-ring and skin around eye greenish yellow, bill slate, lower mandible greenish with slate tip, mouth yellow, feet yellow. Juvenile tawny with rufous feather tips above, throat pale, streaked below, rectrices pointed. **Voice.** (1) Song a persistent, emphatic 3-note call, falling in pitch, repeated at rate of 10 songs/25 sec. (2) Call a loud melodious "do-you?", the first note higher and louder, the second sliding

down from the first, sometimes leading into a rising bubbling series.

Habitat. Forest, mainly unbroken mature forest, also small patches of forest, secondary growth, and gallery forest.

Food and Feeding. Insects, mainly hairy caterpillars. Forages in middle and upper strata of forest and in crowns of trees; accompanies mixed-species flocks of foraging birds.

Breeding. Breeding season apparently in rains in many regions, but between main rains (little dry season) in wetter regions; gonads enlarged Sept-Nov in Angola, oviduct egg Sept in Uelle (Zaire); possible host nests in Dec - Feb in NE Gabon. Brood-parasitic: hosts unknown, possibly Pale-breasted Illadopsis (*Trichastoma rufipennis*) based on identification of cuckoo egg in nest; possibly Finsch's Flycatcher-thrush (*Neocossyphus finschii*) based on uttering of call resembling that of this songbird. Egg deep blue with brown-violet spots, unlike that of other cuckoo species in same area (the egg disappeared); oviduct egg white, unspotted, 23 x 16-4 mm.

Movements. Resident. No known movements.

Status and Conservation. Not globally threatened. Population levels unknown, but species said to be uncommon in Nigeria. Like *C. mehowi*, however, this is a shy and secretive species, noticed only when calling in tops of tall forest trees.

Bibliography. Bannerman (1953), Benson (1964), Britton (1980a), Brosset & Énard (1986), Chapin (1928, 1939), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Dowsett & Forbes-Watson (1993), Dowsett-Lemaire *et al.* (1993), Elgood *et al.* (1994), Fry *et al.* (1988), Gee & Heigham (1977), Grimes (1987), Lippens & Wille (1976), Louette (1981), Louette & Herroelen (1994), Mackworth-Praed & Grant (1957, 1962, 1970), Pinto (1983), Ripley & Heinrich (1966a), Short *et al.* (1990), Snow (1978).

24. Barred Long-tailed Cuckoo

Cercococcyx montanus

French: Coucou montagnard **German:** Bergkuckuck **Spanish:** Cuco Colilargo Montano
Other common names: Barred Cuckoo

Taxonomy. *Cercococcyx montanus*, Chapin, 1928, Kalongi (c. 2100 m), Butahu Valley, Ruwenzori Range, Zaire.

Forms a superspecies with *C. olivinus*. Two subspecies recognized.

Subspecies and Distribution.

C. m. montanus Chapin, 1928 - montane forests of EC Africa from Ruwenzori to L Tanganyika.

C. m. patulus Friedmann, 1928 - Kenya to S Zaire, Zambia, E & S Tanzania, Malawi, E Zimbabwe and Mozambique.

Descriptive notes. 32-34 cm; 54 g. Adult dull olive-brown above, feathers with rufous edges, tail long, rectrices broad, tipped white or pale rufous; white below, barred blackish, often with pale buff wash; skin around eye yellow, iris brown, bill black, greenish at base, feet yellow. Juvenile (*patulus*) with cinnamon-rufous edges to dorsal feathers, streaked below, upper breast and throat blackish with scaly mottling, rectrices pointed. Races differ in size and colour tone: *montanus* smaller, dark above with greenish sheen; *patulus* larger, paler. **Voice.** Song long, 40 sec, starting like whistled "do-you" of *C. olivinus* or *Cuculus solitarius*, leading to 3-syll

lable whistles with first and third notes accented, "pi-pi-ti", sometimes with "pi-pi" syllables at end; series is repeated, becoming more and more rapid and emphatic. Sings mainly during hours before sunrise, and during day if the weather is foggy and humid. Calls from canopy of tall trees, often at night.

Habitat. Forest, montane in most areas, in E Africa also riparian and lowland, coastal thickets and forest-savanna mosaic. To 2800 m.

Food and Feeding. Insects, mainly hairy caterpillars, taken in foliage of trees; occasionally small snails.

Breeding. Few egg dates, apparently breeds in rainy season; in Malawi, calls Dec-Apr, in E Tanzania Sept-Dec. Brood-parasitic: suspected hosts Sharpe's Akalat (*Sheppardia sharpei*) and other akalats, also African Broadbill (*Smithornis capensis*). Egg (laid in captivity) white with few reddish spots, similar to *Sheppardia* egg, another oviduct egg white like *Smithornis* egg; 21 x 15 mm.

Movements. Resident, with some altitudinal and middle-distance movements, including nocturnal movements.

Status and Conservation. Not globally threatened. Although this species seems to be uncommon, it is, like its congeners, secretive and generally overlooked, except when singing. Locally common in forest between 1700 and 2100 m on E slopes of Mt Kenya and on S slopes of the Aberdares: common between 900 and 1600 m in Usambara Mts.

Bibliography. Benson (1964), Benson & Benson (1977), Britton (1977, 1980a), Britton & Zimmerman (1979), Chapin (1928), Clancey (1985, 1996), Dean *et al.* (1974), Dowsett (1990), Dowsett & Forbes-Watson (1993), Evans *et al.* (1994), Fry *et al.* (1988), Ginn *et al.* (1989), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette & Herroelen (1994), Mackworth-Praed & Grant (1957, 1962, 1970), Maclean (1993), Ripley & Heinrich (1966b), Rowan (1983), Short *et al.* (1990), Stjernstedt (1984), Taylor & Taylor (1988), Snow (1978), Zimmerman *et al.* (1996).

Genus *CACOMANTIS* S. Müller, 1843

25. Banded Bay Cuckoo

Cacomantis sonneratii

French: Coucou de Sonnerat **German:** Sonneratkuckuck **Spanish:** Cuco Bayo
Other common names: Indian Banded Bay/Banded/Bay-banded Cuckoo

Taxonomy. *Cuculus Sonneratii* Latham, 1790, North Cachar Hills, India.

Sometimes placed in monotypic genus *Penthoceryx*; alternatively included in *Cuculus* by some authors. Five subspecies recognized.

Subspecies and Distribution.

C. s. waiti (Stuart Baker, 1919) - Sri Lanka.

C. s. sonneratii (Latham, 1790) - India and Nepal through Bangladesh and Myanmar to SW China, Thailand and Indochina.

C. s. malayanus (Chasen & Kloss, 1931) - Peninsular Malaysia.

C. s. schlegeli (Junge, 1948) - Sumatra, Borneo and Palawan (SW Philippines).

C. s. musicus (Ljungh, 1804) - Java.

Descriptive notes. 22 cm; 37 g. Adult bright rufous or bay above, barred with brown, whitish supercilium, white line under eye, tail rufous with subterminal black band and narrow white tip; whit-

note "smoke-yer-pepper", faster and more plaintive than in *Cuculus micropterus*; also a rising call of 3-4 slow whistled notes, then 3-6 faster notes, rising in pitch to sudden stop.

Habitat. Open or dense broadleaf forest, deciduous and evergreen, forest edge, secondary scrub, cultivated lands. Lowlands to 900 m, more rarely to 1500 m, in Himalayas occasionally to 2400 m.

Food and Feeding. Insects, especially caterpillars (Pieridae, Notodontidae, Arctidae), but also bugs and grasshoppers.

Breeding. Breeding season in India varies with that of its hosts, Feb-Aug; in Sri Lanka young in Jun and Oct; in Malaysia sings Jan-May. Brood-parasitic: hosts include Common Iora (*Aegintha tiphia*) in India and Java, Scarlet Minivet (*Pericrocotus flammeus*) in Sri Lanka. Eggs mimic those of *Aegintha*, white with sparse reddish brown marks; 18 x 14 mm. Nestling evicts host's eggs and chicks.

Movements. Resident in SE Asia, e.g. in Borneo, Thailand and Malay Peninsula, but partially migratory in India, where widely scattered in monsoons. In Nepal possibly a summer visitor only, Feb-Oct. Unknown whether those in Philippines are local breeders or non-breeding visitors.

Status and Conservation. Not globally threatened. Common or fairly common in much of its range, for example in Sri Lanka, Myanmar, Peninsular Malaysia and Greater Sundas, but uncommon in Nepal and Thailand.

Bibliography. Abdulali (1943), Ali & Ripley (1981), Baker (1906-1907), van Balen (1991), Becking (1981), Deignan (1945), Delacour & Jabouille (1931), Dickinson *et al.* (1991), Harrison (1969b), Harvey (1990), Hellebrekers & Hoogerwerf (1967), Junge (1948), Lekagul & Round (1991), MacKinnon & Phillips (1993), Madoc (1976), Majumdar *et al.* (1992), van Marle & Voous (1988), Medway & Wells (1976), Phillips (1948, 1978), Price (1979), Ripley (1982), Smythies (1981, 1986), Sody (1989), Stepanyan (1995).

26. Plaintive Cuckoo

Cacomantis merulinus

French: Coucou plaintif

German: Klagekuckuck

Spanish: Cuco Plañidero

Other common names: Brain-fever bird; Indian Plaintive Cuckoo, Grey-bellied Cuckoo (*passerinus*); Rufous-bellied Plaintive Cuckoo, Grey-breasted Brush Cuckoo (*merulinus*)

Taxonomy. *Cuculus merulinus* Scopoli, 1786, Panay, Philippines.

Included in *Cuculus* by some authors. Grey-bellied form *passerinus* sometimes recognized as a distinct species on basis of reported sympatry in NE India, but songs of *passerinus* and *merulinus* are the same, their juvenile plumages are similar, and the host species of *passerinus* appear to be the same as for races *querulus* and *merulinus*, indicating a similar ecological role too. Situation unclear in E Nepal, where race *querulus* was reported twice in 1980's, during Feb. Five subspecies currently recognized.

Subspecies and Distribution.

C. m. passerinus (Vahl, 1797) - Himalayas of N Pakistan and N India E to Nepal, Sikkim, Bhutan and possibly Assam, and S through peninsular India to Nilgiris and Wynad (Kerala); winters S to Sri Lanka and Maldiv Is.

C. m. querulus Heine, 1863 - Assam and Lower Bengal E to S China (including Hainan), and S through Myanmar, Thailand, Laos and Vietnam to N Peninsular Malaysia; some migrate S to peninsular India and SE Asia.

C. m. threnodes Cabanis & Heine, 1863 - S Peninsular Malaysia, Sumatra and Borneo.

C. m. lanceolatus (S. Müller, 1843) - Java and Sulawesi.

C. m. merulinus (Scopoli, 1786) - Philippines.

Descriptive notes. 18-23.5 cm; 22-25 g. Adult of race *passerinus*: dark grey above, lightly glossed green, tail blackish with white tip; chin to breast dark grey, belly and undertail-coverts whitish or grey; rare type all sooty-blackish with brownish tail tip; eye-ring blackish, iris red to brown, some with yellowish outer circle, bill blackish above, yellow below, feet yellow. Female also occurs in rufous morph, bright rufous above, barred with black, plain rufous tail, throat and breast, rest of underparts dark-barred whitish. Juvenile variable, some all dark grey, finely barred whitish on belly, others rufous with crown light rusty-brown and streaked darker brown.

back and wings barred rusty and dark brown (rusty bars wider than dark brown bars), tail black with white bars and with or without rufous edge, underparts black-barred whitish. Races differ mainly in plumage: *querulus* brown above, throat and breast grey (often washed rufous), belly rufous; *threnodes* barely paler buff-rufous below than *querulus*; *merulinus* pale buff below, breast often washed grey; *lanceolatus* often paler brown above, greyish white below merging into pale rufous-buff belly and vent. VOICE. Rising song a 3-note phrase, "tay-ta-tee", repeated on rising scale; cadence song an accelerating trill on descending scale, "tee-tee-tee-tee-tita-tita-tita-tee", 4 slow notes followed by 4 rapid notes. In India, a plaintive clear whistle, "ka-veer". Call "piter" or "tchree", attributed to female. No geographic variation in song is known, when considered for each call type.

Habitat. Open woodland, secondary forest, scrub, brush, gardens and cultivated areas, including in towns and villages, also grassy plains and swamps. Lowlands to c. 2000 m; in Nepal mostly to 1400 m, rarely to 2135 m.

Food and Feeding. Insects, mainly hairy caterpillars (Saturniidae) but also hairless ones (Notodontidae), beetles, bugs, termite soldiers, other soft-bodied insects; also fruit. Appears in foliage canopy, where an active and restless forager.

Breeding. Breeds May-Jun in Kalimantan, Jun-Sept in India, Apr-Aug in N Thailand. Brood-parasitic: hosts mainly warbler species with closed nests with narrow entrance, e.g. Ashy Prinia (*Prinia socialis*), Common Tailorbird (*Orthotomus sutorius*) and Zitting Cisticola (*Cisticola juncidis*) in In-

dia, Yellow-bellied Prinia (*Prinia flaviventris*), Olive-backed Taylorbird (*Orthotomus sepium*) and *C. juncidis* in Java. Eggs dull, light buff to green with light olive marks; 18 x 12 mm. Evicts host's eggs.

Movements. Resident and seasonally migratory. In Nepal a breeding visitor, mainly late Apr to Aug; in Yunnan (SW China), present Feb-Oct. In Sri Lanka, *passerinus* arrives with the dry NE monsoon in Oct and leaves in Apr, does not sing, no breeding records. Many specimens from Java differ from local resident race *lanceolatus*, but match N race *querulus*, indicating immigration from N during latter's non-breeding season.

Status and Conservation. Not globally threatened. Common throughout most of range, for instance in India, Myanmar, Malaysia and Greater Sundas; very common in Thailand; fairly common in Philippines. In Nepal, however, said to be rather scarce, though probably overlooked; nearly all observations there are of *passerinus*, and definitive sightings of *querulus* are extremely rare. In Sri Lanka, common in winter in dry zones and in gardens, rare in the wet zone, casual straggler in the hills.

Bibliography. Abdulali (1971), Ali & Ripley (1981), Ali & Whistler (1937), Ali *et al.* (1996), Baker (1906-1907), Becking (1981), Bharucha (1982), Biswas (1951a, 1960), Cheng Tsohsin (1987), Coates & Bishop (1997), Deignan (1945), Dickinson *et al.* (1991), Échécopar & Hüe (1978), Harrison (1969b), Hartert (1925c), Harvey (1990), Hellebrekers & Hoogerwerf (1967), Legge (1880), Lekagul & Round (1991), Livesey (1939), MacKinnon & Phillips (1993), Madoc (1976), Majumdar *et al.* (1992), van Marle & Voous (1988), Medway & Wells (1976), Oates & Blanford (1895), Osmaston (1916), Parkes (1960b), Phillips (1948, 1978), Rabor (1977), Ripley (1982), Roberts (1991), Smythies (1960, 1981, 1986), Sody (1989), Stanford (1931), Stepanyan (1995), Stresemann (1912, 1940), Wait (1925), Watling (1983), Whistler (1944, 1949), White & Bruce (1986), Zacharias & Gaston (1993).

27. Brush Cuckoo

Cacomantis variolosus

French: Coucou des buissons

German: Buschkuckuck

Spanish: Cuco Varioloso

Other common names: Square-tailed/Grey-headed Cuckoo; Rufous-breasted Brush Cuckoo (*lepidus*); Indonesian/Rusty-breasted (Brush) Cuckoo (*sepulcralis*)

Taxonomy. *Cuculus variolosus* Vigors and Horsfield, 1827, Paramatta, New South Wales.

Sometimes placed in *Cuculus*. Form *sepulcralis* (incorporating *everetti*, *virescens*, *aeruginosus*, *infaustus*) is often treated as a distinct species on grounds of claimed morphological and vocal differences; sometimes reckoned to be closer to *C. merulinus*. Several additional island races have been described, but are nowadays considered invalid. Eleven subspecies recognized.

Subspecies and Distribution.

C. v. sepulcralis (S. Müller, 1843) - S Thailand and Peninsular Malaysia through Sumatra, Borneo, Java, Bali and Philippines to Lesser Sundas (Lombok, Sumbawa, Flores, Sumba).

C. v. everetti Hartert, 1925 - SW Philippines (Basilan and Sulu Is.).

C. v. virescens (Brüggemann, 1876) - Sulawesi.

C. v. aeruginosus Salvadori, 1878 - W & C Moluccas (Sula, Buru, Ambon, Seram).

C. v. infaustus Cabanis & Heine, 1863 - N & E Moluccas (Morotai, Tidore, Ternate, Halmahera, Bacan, Obi, Seram Laut, Watubela, Kai), New Guinea and islands to NE.

C. v. oreophilus Hartert, 1925 - highlands of E & S New Guinea.

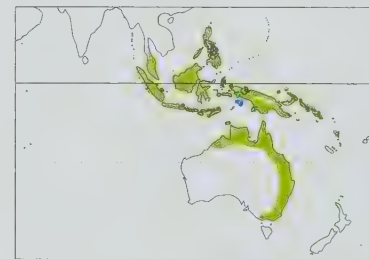

C. v. blandus Rothschild & Hartert, 1914 - Admiralty Is.

C. v. macrocerus Stresemann, 1921 - Bismarck Archipelago (except New Hanover), Tabar I.

C. v. websteri Hartert, 1898 - New Hanover.

C. v. addendus Rothschild & Hartert, 1901 - Solomon Is.

C. v. variolosus (Vigors & Horsfield, 1827) - N & E Australia; winters N to Aru Is, Kai Is, Moluccas, New Guinea, W Papuan islands and Lesser Sundas (Timor, Kisar).

Descriptive notes. 21-28 cm; 34 g. Adult male *sepulcralis* grey above, head grey, wings brown, tail black with white tip and white notches on outer edges; rufous below, unbarred, chin pale grey, undertail broadly barred brown with thin whitish notching on inner webs; eye-ring yellow, iris brown (inner rufous, outer ring whitish), bill black with yellow below, feet yellow. Female finely barred grey below. Juvenile has head, back and wings barred buff and dark brown (brown bars wider than buff bars; darker than juvenile *C. merulinus*), tail dark brown, barred rufous and (rarely) white, black-barred white below, iris whitish grey or pale light

brown. Races differ mainly in plumage coloration: *everetti* darker below, chin rufous, wing shorter; *virescens* greenish brown above, tail with white only at tip, darker below, throat and breast grey (*aeruginosus* similar but slightly darker); *variolosus* brownish grey above, head light grey, pale grey below, breast and belly buff, eye-ring more often grey, iris dark brown, bill black; *infaustus* darker above, breast and upper belly rufous-grey, eye-ring yellow or grey, feet olive or brownish; *oreophilus* averages shorter-winged, larger-billed than *infaustus*, eye-ring dark; *blandus* grey on throat and upper breast (may be washed rufous), rufous belly; *macrocerus* belly grey, rufous or intermediate, tail as *virescens* but longer, eye-ring grey or yellow; *websteri* grey below, tail shorter; *addendus* large, green-glossed blackish above, throat grey, breast and belly dark rufous to rufous-buff, eye-ring yellow. VOICE. Song a series of c. 7-8 mournful whistled notes, each descending, "fear-fear-fear...", series starting high and becoming lower in pitch (or on same pitch); also a shrill rising 3-note phrase, "where's the tea", and a single "referee-whistle". On Bougainville, song a series of notes, rising or falling, and more trilled at end.

Habitat. Rainforest, secondary forest, scrub, mangroves, waterside thickets of honeymyrtle (*Melaleuca*), plantations, village groves, in undergrowth. Lowlands to c. 600 m in Thailand, to 1200 m in Peninsular Malaysia, Greater Sundas and Solomon Is., to 1300 m in New Guinea, mainly 1500-2500 m in Sulawesi, sea-level to 2000 m in Philippines.

Food and Feeding. Insects, mainly caterpillars (hairless and hairy: Pieridae, Lasiocampidae, Saturniidae, Arctidae; also Lepidoptera eggs), also grasshoppers, beetles, bugs, wasps; spiders, snails. Takes prey from leaves and branches within the foliage of trees and bushes.

Breeding. Breeds in rains in Australia, where Sept-Jan in N Queensland, Dec-Mar in Kimberley region. Brood-parasitic, with more than 60 species of host recorded, including: Chestnut-naped Forktail (*Enicurus ruficapillus*) in Borneo; Olive-backed Sunbird (*Nectarinia jugularis*) in Sulawesi; tailorbirds (*Orthotomus*) in Sumatra; Long-tailed Shrike (*Lanius schach*), flycatchers (*Culicicapa*, *Cyornis*, *Ficedula hyperythra*), fantails (*Rhipidura*) and Pied Stonechat (*Saxicola caprata*) in Java; *S. caprata* on Flores; Buru Yellow White-eye (*Zosterops buruensis*) on Buru; White-shouldered Wren (*Malurus alboscapulatus*), Yellow-tinted Honeyeater (*Lichenostomus flavescens*), Lemon-breasted Flycatcher (*Microeca flavigaster*) and others in New Guinea; *Rhipidura*, flycatchers (*Myiagra*), small honeyeaters (*Ramsayornis*, *Melithreptus*), Purple-crowned Fairy-wren (*Malurus coronatus*) and robins (*Petroica*), both open- and closed-nest hosts, in Australia; and Chestnut-bellied Monarch (*Monarcha*

castaneiventris) in Solomon Is. Eggs (Australia) variable: whitish with brownish spots around large end, or whitish with few tiny spots of black, each type corresponding to a host species; 19 x 14 mm; incubation less than 13 days. Hatchling (*variolosus*) naked, skin black; evicts host's eggs and young; fledges in 17-19 days, fed for a month after leaving nest.

Movements. Resident in lowlands of Malaysia and Thailand, and in much of range elsewhere. S Australian birds migrate N after breeding, while those in tropical regions of Australia are partially migratory to resident; non-breeding visitors from these regions occur N to Timor, the Moluccas and New Guinea.

Status and Conservation. Not globally threatened. Common in the Philippines; widespread in lowland forest in Sabah; abundant in lower and middle tiers of open forest in New Britain. Although it seems to be uncommon in NW of range, in Thailand, it becomes more numerous farther S, in Malaysia and the Greater Sundas; in Sulawesi, not uncommon at Dumoga-Bone National Park. In Australia this cuckoo is sometimes common, but its numbers fluctuate somewhat.

Bibliography. Amadon (1942), Beehler *et al.* (1986), Beruldsen (1978, 1980), Blakers *et al.* (1984), Brooker & Brooker (1989a), Cain & Galbraith (1956), Coates (1985), Coates & Bishop (1997), Cranbrook & Wells (1981), Diamond (1975a), Diamond & LeCroy (1979), Dickinson, Kennedy & Parkes (1991), Dickinson, Kennedy, Read & Rozendaal (1989), Gilliard (1950b), Gilliard & LeCroy (1967a), Goodman *et al.* (1995), Hall (1974), Hartert (1925c, 1930), Hellebrekers & Hoogerwerf (1967), Lekagul & Round (1991), MacKinnon & Phillipps (1993), Madoc (1976), van Marie & Voous (1988), Mayr (1944b), Mayr & Meyer de Schauensee (1939b), Mayr & Rand (1937), Medway & Wells (1976), Ottow & Verheijen (1969), Parkes (1960b, 1973), Rand & Gilliard (1967), Rozendaal & Dekker (1989), Sibley (1951), Siebers (1930), Smythies (1981), Sody (1989), Storr (1980, 1984b), Strahan (1994), Stresemann (1912, 1914), Watling (1983), White & Bruce (1986).

28. Moluccan Cuckoo

Cacomantis heinrichi

French: Coucou de Heinrich **German:** Molukkenkuckuck **Spanish:** Cuco Moluqueño
Other common names: Heinrich's Cuckoo, Heinrich's/Moluccan Brush Cuckoo

Taxonomy *Cacomantis heinrichi* Stresemann, 1931, Sibela, 1500 m, Bacan.
Sometimes placed in *Cuculus*. Formerly considered a colour morph of *C. variolosus*, but is smaller and shorter-winged than sympatric form of latter. Monotypic.

Distribution. Bacan and Halmahera (N Moluccas).

Descriptive notes. 23 cm. Adult dark olive-brown above; throat dark grey, breast and belly dark rufous, undertail-coverts dark reddish; eye-ring greyish, iris dark brown with lighter outer ring, feet yellow. Juvenile dark above, barred below. Adult differs from sympatric *C. variolosus infaustus* in brighter yellow feet; also smaller in both wing length and overall size. **Voice.** Unknown.

Habitat. Forest, at 1000-1500 m.

Food and Feeding. Unknown; presumably mainly insects.

Breeding. No information available.

Movements. No movements known.

Status and Conservation. Not globally threatened. Data Deficient. Known only from five specimens, all collected in 1931; species has apparently not been seen since then. Because of its restricted range, it may be at risk, but data are insufficient to determine its conservation status. Research needed in order to establish basic biological and ecological requirements, as well as current population levels.

Bibliography. Andrew (1992), Anon. (1995b), Coates & Bishop (1997), Collar *et al.* (1994), Hartert (1925c), Inskipp *et al.* (1996), Jepson (1997), Stresemann (1931), Sujatnika *et al.* (1995), Wheatley (1996), White & Bruce (1986).

29. Chestnut-breasted Cuckoo

Cacomantis castaneiventris

French: Coucou à poitrine rousse **German:** Rostbauchkuckuck **Spanish:** Cuco Ventricastaño

Taxonomy. *Cuculus* (*Cacomantis*) *castaneiventris* Gould, 1867, Cape York district, Queensland, Australia.

Sometimes placed in *Cuculus*. Three subspecies recognized.

Subspecies and Distribution.

C. c. arfakianus Salvadori, 1889 - W Papuan islands and W New Guinea from Vogelkop to Weyland and Snow Mts and E to R. Fly.

C. c. weiskei Reichenow, 1900 - E New Guinea, from Sepik region, Huon Peninsula and upper R Purari eastwards.

C. c. castaneiventris (Gould, 1867) - Aru Is and NE Australia (E coast of Cape York and NE Queensland).

Descriptive notes. 24 cm; 34 g. Adult slate-grey above, bright chestnut below; eye-ring yellow, iris brown, bill black and yellow, feet yellow. Juvenile unbarred dark grey-brown above, tail with rufous outer edge, unbarred brown to buff below. Race *arfakianus* dark chestnut below, smaller; *weiskei* green-glossed blackish above, darker chestnut below, size as *arfakianus*. **Voice.** Loud 3-note mournful whistled "seei-to-seei", first note upslurred, second shorter, third upslurred and trilled; also a descending trill, and a single whistling "chir-rip".

Habitat. Interior of montane forest, rain forest and scrub along riverbanks; also in mangroves, but rare at sea-level, mainly occurring at 1200-2100 m.

Food and Feeding. Insects, especially caterpillars. Moves through forest canopy, taking insects; also watches from low perch, and flies to ground; also hovers.

Breeding. Breeds ?Sept/Oct-Dec/Jan in Australia. Brood-parasitic; hosts include Grey-green Scrubwren (*Sericornis arfakianus*) in New Guinea, Tropical Scrub-wren (*S. beccarii*) in Australia. Egg white, freckled reddish; estimated c. 19 x 14 mm.

Movements. In most of range resident, and fairly sedentary, including observations around the year in Cape York, Australia; in extreme S probably occurs only as a non-breeding visitor.

Status and Conservation. Not globally threatened. Overall status unclear, as very few data available on relative abundance throughout range; species appears to be scarce to rare in Cape York Peninsula.

Bibliography. Beehler *et al.* (1986), Beruldsen (1980), Blakers *et al.* (1984), Brooker & Brooker (1989a), Coates (1985), Gilliard & LeCroy (1961), Gregory (1995a, 1995b), Hall (1974), Hartert (1925c), Lindsey, T.R. (1992), Macdonald (1988), Mayr & Rand (1937), McWhirter (1986b), Pizzey & Doyle (1980), Rand & Gilliard (1967), Schodde & Tidemann (1986), Simpson & Day (1996), Storr (1984b), Strahan (1994), Trounson & Trounson (1987).

30. Fan-tailed Cuckoo

Cacomantis flabelliformis

French: Coucou à éventail **German:** Fächerschwanzkuckuck **Spanish:** Cuco Flabelforme
Other common names: Fan-tailed Brush Cuckoo, Ash-coloured Cuckoo

Taxonomy. *Cuculus flabelliformis* Latham, 1801, Sydney area, New South Wales.
Sometimes placed in *Cuculus*. Species formerly listed as *C. pyrrophanus* (or erroneously as *C. pyrrophanus*), due to confusion as to which form had been the original model for the painting used as the basis of the name *flabelliformis*. Five subspecies recognized.

Subspecies and Distribution.

C. f. excitus Rothschild & Hartert, 1907 - mountains of New Guinea.

C. f. flabelliformis (Latham, 1801) - E Australia from Cape York to SE Australia and Tasmania; also SW Western Australia.

C. f. pyrrophanus (Vieillot, 1817) - New Caledonia and Loyalty Is.

C. f. schistaceigularis Sharpe, 1900 - Vanuatu.

C. f. simus (Peale, 1848) - Fiji.

Descriptive notes. 26 cm; 44 g. Adult slate-grey above, tail wedge-shaped, notched white on outer webs; throat grey, breast buff to rufous, undertail with whitish bars ("notching" on edge); eye-ring yellow, iris brown, bill black, feet olive-yellow. Juvenile dark brown above with dull rufous streaks, mottled whitish and black below and indistinctly barred grey and brown. Race *excitus* much darker, greyish black above, grey chin and throat, dusky chestnut below; *pyrrophanus* rich chestnut below, eye-ring grey-brown; *schistaceigularis* grey on throat and upper breast, dark chestnut below; *simus* smaller, slightly paler

chestnut below (also melanistic morph "*infuscatus*", with white confined to tail tip). **Voice.** Descending trill, "peeeeee", also a rising whistle, "p-weet"; female gives loud "chiree".

Habitat. Mainly tall open forests, rainforest, also open woodlands, roadsides, mangroves, heath. In New Guinea, occurs in mountains at 1500-3000 m.

Food and Feeding. Insects, mainly caterpillars, also centipedes, spiders. Forages in foliage, also hawks flying moths and ants.

Breeding. Breeds Aug-Dec in Australia, Nov-Feb in Fiji. Male courtship-feeds female. Brood-parasitic; hosts mainly domed-nest species, include Large-billed Scrubwren (*Sericornis nouhuysi*) in New Guinea; Scarlet Robin (*Petroica multicolor*) in Vanuatu; fairy-wrens (*Malurus*), thornbills (*Acanthiza*) and scrubwrens (*Sericornis*) in Australia (where 17 host species known); and Fiji Warbler (*Vitta ruficapilla*) in Fiji. Egg white, freckled brown and purple; 21 x 15 mm. Hatchling naked, pinkish, in a few days becoming dark brown, gape yellow; evicts host's eggs and young; fledges in 16-17 days.

Movements. Resident in tropics, elsewhere partially migratory or nomadic. Tasmanian breeders move N to Australia. Australian distribution is seasonal in some areas, indicating N and inland post-breeding movements; in Queensland birds "wintering" N of breeding range are mainly immatures. Vagrant or passage migrant in interior Australia. Race *pyrrophanus* occurs irregularly as migrant to E Solomon Is.

Status and Conservation. Not globally threatened. A common species in much of its range and the most numerous cuckoo in parts of E Australia. Population densities in Australian eucalypt woodland are calculated as 0.02-1.1 birds/ha.

Bibliography. Amadon (1942), Ambrose (1987), Beehler *et al.* (1986), Beruldsen (1980), Blakers *et al.* (1984), Bregulla (1992), Brooker & Brooker (1989a), Christidis & Boles (1994), Clunie (1973, 1984), Coates (1985), Gyldestolpe (1955a), Hall (1974), Hartert (1925c, 1930), Hatton (1989), Holyoak (1979), Jansen (1990), Junge (1953), Marchant & Höhn (1980), Mason (1982), Mayr & Rand (1937), Mees (1982a), Noske (1978), Pratt *et al.* (1987), Rand & Gilliard (1967), Rose (1997), Smedley (1983), Smithers (1977), Storr (1984b, 1991), Strahan (1994), Stresemann (1924b), Vuilleumier & Gochfeld (1976).

Genus *CHRYSOCOCCYX* Boie, 1826

31. Black-eared Cuckoo

Chrysococcyx osculans

French: Coucou oreillard **German:** Schwarzhörkuckuck **Spanish:** Cuculillo Orejinegro

Taxonomy. *Chalcites osculans* Gould, 1847, New South Wales. Sometimes placed in monospecific genus *Misocalius*. Monotypic.
Distribution. Australia.

Descriptive notes. 20 cm; 30 g. Adult grey above with slight metallic gloss, long white supercilium, broad black band through eye, pale rump, tail grey with white tip; creamy buff below; eye-ring grey, iris black, bill black, feet dark grey. Juvenile similar, but face markings less distinct, underparts buff. Voice. Descending low whistle, "peeceer".

Habitat. Open scrub, dry woodlands, mallee, mulga, saltflats, waterside forests and thickets; rare in subhumid zone.

Food and Feeding. Insects, mainly caterpillars, also beetles; seeds. Forages in shrubs and on ground; flight swift and direct.

Breeding. Breeds Jun-Oct in W, Aug-Dec in E. Brood-parasitic: hosts small Australian warblers, e.g. Redthroat (*Sericornis brunneus*), Little Fieldwren (*S. sagittatus*). Eggs dark brown, resemble those of *S. brunneus*; 20 x 14 mm. Hatchling naked, black skin; evicts host's eggs and young.

Movements. Migratory or nomadic, breeding in response to rains. Breeds mainly S of Tropic of Capricorn. Breeding visitor Sept-Apr in N Queensland, occurs Apr-Jun in S coastal plains in Queensland; wanders to N Australia outside breeding period, when some birds remain in S Australia. Vagrant or rare non-breeding migrant in Aru Is, New Guinea, Moluccas and Lesser Sundas.

Status and Conservation. Not globally threatened. A fairly common species in most of its habitats except wet, forested coastal areas, where it is uncommon; sometimes irregular in occurrence, and at times very scarce. First reported in Tasmania in 1977.

Bibliography. Beehler *et al.* (1986), Beruldsen (1980), Blakers *et al.* (1984), Brooker & Brooker (1989a), Coates (1985), Coates & Bishop (1997), Friedmann (1968), Hall (1974), Hoskin (1989b), Lindsey, T.R. (1992), Macdonald (1988), Pizzey & Doyle (1980), Rand & Gilliard (1967), Schodde & Tidemann (1986), Simpson & Day (1996), Storr (1980, 1984a, 1984b), Strahan (1994), Tronson & Tronson (1987), White & Bruce (1986).

32. Horsfield's Bronze-cuckoo

Chrysococcyx basalis

French: Coucou de Horsfield **German:** Rotschwanzkuckuck **Spanish:** Cuculillo de Horsfield
Other common names: Australian/Narrow-billed/Rufous-tailed Bronze-cuckoo, Horsfield's Cuckoo(!)

Taxonomy. *Cuculus basalis* Horsfield, 1821, Java.

Asian and Australasian forms of *Chrysococcyx* sometimes placed in genus *Chalcites*. Monotypic.

Distribution. Australia and Tasmania. Winters N to Java and irregularly beyond.

Descriptive notes. 17 cm; 22 g. Adult brownish bronze above, head browner than back, long white supercilium and dark eye-stripe, tail sides rufous, notched white; whitish below, throat lightly streaked, barred bronze on flanks and sides of breast, undertail barred black and white with rufous centre, underside of flight-feathers with rufous-tinged white band; wing feathers often have crisp pale margins, a feature not noted in congeners; eye-ring grey, iris brown to red, bill slender, black, feet grey. Juvenile similar but duller, plain grey-brown above, feathers sometimes buff-edged, flanks faintly barred, iris grey to light brown. Voice. Descending high whistle,

"peeceer", repeated once every 5 sec, faster and higher than that of *C. osculans*.

Habitat. Open woodland, mulga, scrub, including dry interior, spinifex, coastal saltmarsh, generally arid and semi-arid zones.

Food and Feeding. Insects, mainly caterpillars, also beetles (Coccinellidae), bugs. Forages in foliage and on ground; flight swift and direct.

Breeding. Breeding in Western Australia varies with seasonal rains, Aug-Oct in Southwestern Division, Oct-Dec near Perth, Jan-Mar in Kimberley Division, Mar-May and Aug-Sept in Pilbara region. Brood-parasitic: hosts mainly small thornbills (*Acanthiza*), fairy-wrens (*Malurus*), and Australian robins (*Petroica*) and chats (*Ephthianura*); 28 host species known, mainly with domed nests, some with open nests. Eggs whitish with brown flecks; 18 x 12 mm; incubation 11-13 days. Hatchling naked, skin pink and grey, darkening with age, white gape flanges, yellow mouth-lining; evicts host's eggs and chicks; fledges in 17-19 days, fed up to 4 weeks after fledging.

Movements. Partial migrant. A few remain all year in E Australia E of the Dividing Range and also in S of range, but more are resident in N Australia. Some birds spend non-breeding season N of Australia, and occur on passage on islands off the coast. A non-breeding visitor to S New Guinea and W through Indonesia, where generally uncommon to scarce but probably overlooked, though said to be locally common in NW Java from Mar and Apr; occasional in Sumatra and Sulawesi, one record each in Sumbawa, Flores, Natuna Is, Borneo and Singapore.

Status and Conservation. Not globally threatened. Common in much of breeding range, though scarce in Northern Territory and Kimberley Division of Western Australia. Reported breeding densities of 0.1 bird/ha, or 10 birds/km², are reckoned to be unusually high for this species.

Bibliography. Alley (1978), Andrew (1986), Beehler *et al.* (1986), Beruldsen (1980), Blakers *et al.* (1984), Brooker & Brooker (1986, 1989a, 1989b, 1992), Brooker *et al.* (1988), Coates (1985), Coates & Bishop (1997), Debus (1989), Friedmann (1968), Hall (1974), Heron (1977), Holmes (1996), Hoskin (1989a), Johnstone *et al.* (1993), Lindsey, T.R. (1992), Macdonald (1988), MacKinnon & Philipps (1993), van Marle & Voous (1988), Payne (1997), Payne & Payne (1998), Payne *et al.* (1985, 1988), Pizzey & Doyle (1980), Rand & Gilliard (1967), Rose (1997a), Rowley *et al.* (1991), Schodde & Tidemann (1986), Seale (1976), Serventy & Whittell (1976), Simpson & Day (1996), Sody (1989), Storr (1977, 1980, 1984a, 1984b, 1991), Strahan (1994), Tronson & Tronson (1987), White & Bruce (1986).

33. Little Bronze-cuckoo

Chrysococcyx minutillus

French: Coucou menu **German:** Kleiner Bronzekuckuck **Spanish:** Cuculillo Menudo
Other common names: Malay Green Cuckoo, Malay Bronze-cuckoo; Gould's/Rufous Bronze-cuckoo (*russatus* group); Green-cheeked/Dark-backed Bronze-cuckoo (*rufomerus*); Pied Bronze-cuckoo, Island Cuckoo (*crassirostris*)

Taxonomy. *Chrysococcyx minutillus* Gould, 1859, Port Essington, Northern Territory.

Asian and Australasian forms of *Chrysococcyx* sometimes placed in genus *Chalcites*. Species formerly known as *C. malayanus*, but type of that name was a female of *C. xanthorhynchus*. Present species might be better considered to constitute more than one species, but the songs of all forms, where known, are apparently identical. While the forms listed are generally allopatric, and all use the same type of host species, the occurrence of two forms (*cleis*, *aheneus*) in Borneo suggests possible separate species status: *russatus* group (*aheneus*, *jungei*, *misoriensis*, *poecilurus*, *russatus* and undescribed race from Timor) sometimes treated as a distinct species from *minutillus* group (*peninsularis*, *albifrons*, *cleis*, *minutillus* and *barnardi*) due to apparent sympatry without interbreeding in Borneo, but this may involve migrant birds, and both forms interbreed extensively in N Australia (*russatus* with *barnardi*). Races *rufomerus* and *crassirostris* are also often treated as two separate full species, or as races of one distinct species, on grounds of claimed morphological and ecological differences; race *salvadorii* (known only from type specimen) sometimes considered intermediate between these two, and sometimes included within latter race. Thirteen subspecies currently recognized.

Subspecies and Distribution.

C. m. peninsularis Parker, 1981 - extreme S Thailand and Peninsular Malaysia.

C. m. albifrons (Junge, 1938) - N Sumatra and W Java.

C. m. cleis Parker, 1981 - N & E Borneo.

C. m. aheneus (Junge, 1938) - SE Borneo and S Philippines.

C. m. jungei (Stresemann, 1938) - Sulawesi, Madu and Flores.

C. m. rufomerus Hartert, 1900 - Lesser Sundas (Romang, Kisar, Leti, Moa, Sermata, Damar).

C. m. crassirostris (Salvadori, 1878) - Moluccas (Tayandu, Kai) and Tanimbar Is (Yamdena, Larat).

C. m. salvadorii (Hartert & Stresemann, 1925) - Tepa (Babar Is).

C. m. misoriensis (Salvadori, 1875) - lowlands on N coast of New Guinea, and islands off E, N & NW coasts.

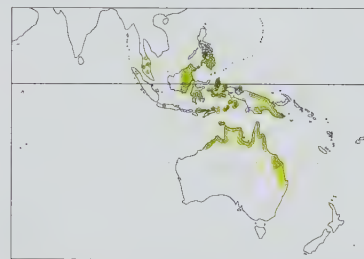

C. m. poecilurus G. R. Gray, 1862 - lowlands on S coast of New Guinea, and islands off W & S coasts including Misool.

C. m. minutillus Gould, 1859 - Moluccas, Lesser Sundas and N Australia, from Kimberley district of NW Australia through Melville I and Arnhem Land to N Queensland (Gulf of Carpentaria to W Cape York).

C. m. russatus Gould, 1868 - N & E Queensland (Cape York along E coast).

C. m. barnardi Mathews, 1912 - E Australia (SE Queensland to NE New South Wales).

Birds from Timor appear to represent a distinct race, as yet undescribed.

Descriptive notes. 15-16 cm; 17 g. Adult male *minutillus* bronze-green above, white forehead, white above eye, bright green crown; tail bronze green (sometimes washed rufous), barred black and white at sides, white tip with black subterminal bar; below white with blackish bars, underwing-coverts barred; eye-ring red, iris red, bill black, feet grey. Female eye-ring tan to yellow or white, iris brown. Juvenile duller, grey-brown above, white to rufous below with trace of barring on flanks, underwing-coverts unbarred or nearly so, eye-ring dull red, iris brown. Races differ widely in plumage: *peninsularis* darker-crowned, face with white frosting, female eye-

ring green; *albifrons* whiter and less barred below; *cleis* slender-billed, more strongly barred below; *barnardi* as *minutillus* but less glossy, wing longer; *russatus* group more rufous (*aheneus* less so), *jungei* with crown and back both frosted brown and slightly glossed, *misoriensis* more rufescent-bronze, *poecilurus* green above lacking rufous or bronze iridescence (but crown glossy dark green), *russatus* bronze-green with tail more rufescent, and rufous below; *rufomerus* dark green above, green cheeks; *salvadorii* has blue-black cheeks and no white above eye, small white wing patch; *crassirostris* green-glossed blackish blue above, white patch on wing. Voice. In *minutillus*, *russatus*, *peninsularis* and Javan *albifrons*, a thin whistled descending "teu teu teu teu" of 4-5 notes with pause after third, also a long descending trill, and two distinct calls: descending "te-te-te-te-te", and tinkling trill. A clear "kiri kiri kiri" is also reported.

Habitat. Lowland forest and forest edge, monsoon forest, honey myrtle (*Melaleuca*) swamp forest, secondary growth, vine thickets, thickets of wattle (*Acacia*) and stringybark (*Eucalyptus tetrodonta*), and mangroves; also frequent in towns and gardens. Generally found in dense lowland vegetation. Occurs from sea-level up to 1400 m; in New Guinea, scarce above 500 m.

Food and Feeding. Insects, mainly caterpillars (Hesperiidae), also beetles (Coccinellidae) and bugs. Forages in tree canopy.

Breeding. In Malaysia eggs in Mar and Aug; breeds Oct-Nov in E Queensland, Sept-Feb in N Queensland, Nov-Mar in Northern Territory. Brood-parasitic: hosts *Gerygone* flycatchers including *G. sulphurea* in Malaysia and Java, *G. magnirostris* in New Guinea and Australia, probably *G. dorsalis* in E Lesser Sundas. Eggs olive-bronze, 21 x 14 mm (Java), olive-brown, 20.5 x 15 mm (New Guinea), bronze with tiny darker spots, 19 x 13 mm (Australia). Hatchling (*minutillus*) pink to black, down on head.

Movements. Partial migrant in Australia, where observed moving across Torres Strait. Race *minutillus* migrates to Lesser Sundas, Moluccas, Sulawesi and New Guinea, but resident throughout year in the Kimberley region and near Darwin, Northern Territory; *barnardi* a partial migrant,

On following pages: 34. Shining Bronze-cuckoo (*Chrysococcyx lucidus*); 35. Rufous-throated Bronze-cuckoo (*Chrysococcyx ruficollis*); 36. White-eared Bronze-cuckoo (*Chrysococcyx meyeri*); 37. Asian Emerald Cuckoo (*Chrysococcyx maculatus*); 38. Violet Cuckoo (*Chrysococcyx xanthorhynchus*); 39. Yellow-throated Cuckoo (*Chrysococcyx flavigularis*); 40. Klaas's Cuckoo (*Chrysococcyx klaas*); 41. African Emerald Cuckoo (*Chrysococcyx cupreus*); 42. Diederik Cuckoo (*Chrysococcyx caprius*).

occurs in austral winter in N Queensland N of its breeding range and in S New Guinea. Other races are resident, but some birds in Thailand may possibly be only non-breeding visitors from farther S. **Status and Conservation.** Not globally threatened. In Australia, appears to be locally common to fairly common, but its occurrence is somewhat erratic. It is uncommon in W of range, and in some parts even scarce. Form *rufomerus*, endemic to six small islands E of Timor, and regarded by some authorities as a full species, has been considered threatened; its status and any possible threats to its population are, however, unknown, and this taxon is now classified as Data Deficient for purposes of conservation requirements. In Sulawesi, commonly heard in forest edge habitat in hilly areas, and also in town streets that are lined with trees; in Jul 1988, at least 16 individuals were heard calling along a stretch of road only 7 km long.

Bibliography. Andrew & Holmes (1990), Beehler *et al.* (1986), Berger (1955), Beruldsen (1980), Blakers *et al.* (1984), Brooker & Brooker (1989a), Christidis & Boles (1994), Coates (1985), Coates & Bishop (1997), Collar & Andrew (1988), Collar *et al.* (1994), Deignan & Amos (1950), Dickinson *et al.* (1991), Ford (1981), Friedmann (1968), Hall (1974), Hellebrekers & Hoogerwerf (1967), Holmes & Burton (1987), Junge (1938a), Lekagul & Round (1991), MacKinnon & Philipps (1993), van Marle & Voous (1988), Mayr & Rand (1937), McGill & Goddard (1979), Medway & Wells (1976), Mees (1982a), Parker (1981), Rand & Gilliard (1967), Smythies (1981), Sody (1989), Storr (1977, 1980, 1984b), Stresemann (1914), Sujatnika *et al.* (1995), Watling (1983), White & Bruce (1986).

34. Shining Bronze-cuckoo

Chrysococcyx lucidus

French: Coucou éclatant **German:** Bronzekuckuck **Spanish:** Cuculillo Broncíneo
Other common names: Golden Bronze-cuckoo, Shining Cuckoo, Golden Cuckoo

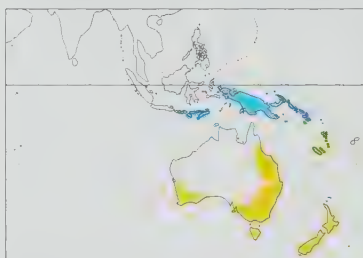

Taxonomy. *Cuculus lucidus* J. F. Gmelin, 1788, Queen Charlotte Sound, New Zealand. Asian and Australasian forms of *Chrysococcyx* sometimes placed in genus *Chalcites*. Within present species, Australian birds are sometimes recognized as a separate race, *plagosus*, with wider bill, more white on side of face, no white on forehead, and more brown or bronze (less green) gloss, but even in Western Australia not all individuals are distinct from birds in New Zealand; both bronze-backed and green-backed birds occur in breeding season in both areas, as do birds with and without white forehead spots. Birds on Malekula I, Vanuatu, described as race *aeneus*, but not morphologically distinct from other populations of the island region. Three subspecies recognized.

Subspecies and Distribution.

C. l. harterti (Mayr, 1932) - Rennell I and Bellona I (S Solomons).

C. l. layardi Mathews, 1912 - New Caledonia and Loyalty Is, Vanuatu, Banks Is and Santa Cruz Is.

C. l. lucidus (J. F. Gmelin, 1788) - Australia, Tasmania and New Zealand; migrates to New Guinea region, N Melanesia and Lesser Sundas.

Descriptive notes. 17 cm; 23 g, but up to 50 g before migration. Adult bronze-green above, tail green, face variably whitish (including lores); white below, barred greenish to bronze, throat white or narrowly barred; eye-ring grey, iris grey to brown, bill black, feet dark grey. Juvenile duller, inconspicuously barred on flanks, iris grey to pale brown. Races *layardi* and *harterti* smaller, former with face dark (dark extends below eye), female *harterti* rufous on throat. **VOICE.** Series of upslurred whistled notes like those used to call a dog, "fee, fee, fee ..."; also a descending "pee-er".

Habitat. Forest, woodland, scrub, mainly areas with more than 380 mm of rainfall; sea-level to 1000 m. In non-breeding range, occurs in secondary growth, forest edge, scrub, savanna, village gardens, *Casuarina* groves, and also forest canopy, occasionally mangroves and pine plantations; from sea-level to 1920 m on New Guinea, and to at least 1000 m on Bougainville.

Food and Feeding. Insects, mainly caterpillars. Forages in tree and shrub canopy, also on ground. Joins mixed-species flocks of insectivorous resident passerines.

Breeding. Breeds Jul to early Dec in Queensland, Oct-Dec in Western Australia. Brood-parasitic: hosts in New Zealand, Grey Warbler (*Gerygone igata*); in Australia, thornbills (*Acanthiza*), fairy-wrens (*Malurus*) and robins (*Petroica*) known, hosts with both domed nests and open nests. Eggs unmarked bronze, in colour and pattern unlike that of any host in Australia (dark egg is hard to see in closed nest); 18 x 12 mm; incubation 13-16 days (longer dates are in New Zealand). Nestling in New Zealand with long white down, gape flange white; in Australia naked or nearly naked at hatching, skin pinkish orange to greenish grey, gape flange (SW Australia) yellow; evicts host's eggs and young; fledges in 18-20 days, cared for by foster parent for up to 5 weeks further.

Movements. Migrant and partial migrant. Nominat *lucidus* breeding in Australia and New Zealand is a long-distance migrant across seas to equatorial non-breeding grounds, mainly in New Guinea and the Solomon Is, where silent; observed on passage across Torres Strait. Occurs in Queensland at all seasons, moving N in autumn and S in spring. A few remain in SE Australia and Tasmania in austral winter. Island races *layardi* and *harterti* are resident.

Status and Conservation. Not globally threatened. Locally common in areas of wooded country in New Zealand and Australia. Breeding densities in Australian eucalypt woodland calculated at c. 1 bird/km². In Vanuatu, apparently more widespread and numerous in past.

Bibliography. Beehler *et al.* (1986), Berger (1955), Beruldsen (1980), Blackburn (1962, 1963), Blakers *et al.* (1984), Bradley & Wolff (1956), Bregulla (1992), Brooker & Brooker (1986, 1989a, 1989b, 1992), Brooker *et al.* (1988), Chambers (1989), Coates (1985), Coates & Bishop (1997), Diamond (1975a), Edgar (1961), Fell (1947), Fitzgerald (1960), Friedmann (1968), Gill (1978, 1980a, 1982a, 1982b, 1983a, 1983b, 1989), Hall (1974), Kendrick (1994), MacDonald & Gill (1991), Marchant (1972), Mayr (1932), McClelland & Moore (1991), McLean & Rhodes (1991), Noske (1994), Payne (1997), Payne & Payne (1998), Rand & Gilliard (1967), Rose (1997a), Rutgers & Norris (1972), Schodde *et al.* (1983), Skinner (1986), St. Paul (1976), Storr (1984a, 1984b, 1991), Wakefin (1967), White & Bruce (1986).

35. Rufous-throated Bronze-cuckoo

Chrysococcyx ruficollis

French: Coucou à gorge rousse **German:** Rothals-Bronzekuckuck **Spanish:** Cuculillo Gorgirrojo
Other common names: Reddish-throated Bronze-cuckoo, Mountain Bronze-cuckoo

Taxonomy. *Lamprococcyx ruficollis* Salvadori, 1875, Hatam, Arfak Mountains, New Guinea.

Asian and Australasian forms of *Chrysococcyx* sometimes placed in genus *Chalcites*. Monotypic.

Distribution. New Guinea.

Descriptive notes. 16 cm; 23.5 g (laying female). Adult greenish above, with forehead, face, throat and breast rufous, barred white and green below; iris from reddish brown in male to brown in female, bill black, feet olive grey. Juvenile greenish above, grey below, flanks faintly barred grey, iris dark brown. **VOICE.** Song 8-9 identical high-pitched, downslurred whistles, 2/sec, higher-pitched than song of *C. meyeri*.

Habitat. Montane forest and edge in New Guinea highlands; mainly at 1800-2600 m, up to 3350 m.

Food and Feeding. Insects, mainly caterpillars, also flying insects. Joins mixed-species flocks

of foraging birds; sits motionless, staring and peering about for insects under small branches, then moves and seizes the insect.

Breeding. No information available. Presumably brood-parasitic.

Movements. Unknown.

Status and Conservation. Not globally threatened. Few data are available on relative abundance, but species seems to be uncommon to rare within its relatively restricted range. Biology and ecology virtually unknown; research required.

Bibliography. Andrew (1992), Anon. (1994b), Beehler (1978b), Beehler *et al.* (1986), Coates (1985), Coles (1995), Diamond (1972a), Friedmann (1968), Hartert (1930), Jepson (1997), Junge (1953), Mayr & Rand (1937), Parker (1981), Rand & Gilliard (1967).

36. White-eared Bronze-cuckoo

Chrysococcyx meyeri

French: Coucou de Meyer **German:** Rotschwingen-Bronzekuckuck **Spanish:** Cuculillo Orejiblanco
Other common names: Meyer's Bronze-cuckoo, Mountain Bronze-cuckoo

Taxonomy. *Chrysococcyx meyeri* Salvadori, 1874, Hatam, Arfak Mountains, New Guinea.

Asian and Australasian forms of *Chrysococcyx* sometimes placed in genus *Chalcites*. Monotypic.

Distribution. Mountains of New Guinea and Batanta I.

Descriptive notes. 15 cm; 20 g. Adult glossy green above, crown green, ear-coverts white, female with chestnut forecrown; white below with prominent glossy green barring, undertail black with white bars on inner webs of outer feathers; large rufous patch on flight-feathers; eye-ring red in male to grey in female, iris pale brown to grey-brown, darker on inner rim, bill black, feet blue-grey. Juvenile grey-brown above, head grey, tail rufous-grey with dark grey near tip, grey below, iris brown, feet light brown. **VOICE.** Song 5-8 high-pitched clear notes, "peer peer peer...", dropping slightly in pitch, final note preceded by a pause; also a complex song

of 4 pairs of downslurred notes, the pairs rising and falling.

Habitat. Inhabits forests, including forest edge, also garden shade trees, mainly in lower montane habitats at 500-1800 m.

Food and Feeding. Insects, caterpillars in canopy leaves. A regular member in mixed-species foraging flocks.

Breeding. No information available. Presumably brood-parasitic.

Movements. Unknown.

Status and Conservation. Not globally threatened. Virtually nothing known about biology, ecology and population numbers; research required.

Bibliography. Andrew (1992), Austin & Kuroda (1953), Beehler (1978b), Beehler, Burg *et al.* (1994), Beehler, Pratt & Zimmerman (1986), Coates (1985), Diamond (1972a), Eastwood (1995b), Friedmann (1968), Gilliard & LeCroy (1961, 1967b), Gregory (1995a, 1995b), Hartert (1930), Jepson (1997), Junge (1953), Mayr & Rand (1937), Parker (1981), Rand & Gilliard (1967).

37. Asian Emerald Cuckoo

Chrysococcyx maculatus

French: Coucou émeraude **German:** Prachtkuckuck **Spanish:** Cuculillo Esmeralda Asiático
Other common names: Oriental/Asiatic Emerald Cuckoo, Emerald Cuckoo

Taxonomy. *Trogon maculatus* J. F. Gmelin, 1788, Sri Lanka.

Asian and Australasian forms of *Chrysococcyx* sometimes placed in genus *Chalcites*. Monotypic.

Distribution. Himalayas from about Garhwal E through Nepal, Assam, Manipur, Bangladesh, SE Tibet and SC China (Sichuan, Yunnan), S to Myanmar, NW Thailand and C Vietnam; also Andaman and Nicobar Is, but possibly only non-breeding visitor to latter. Winters S to N Vietnam and Malay Peninsula, with apparently small numbers reaching Sumatra.

Descriptive notes. 17 cm; 24 g. Adult male glossy green above and from chin to upper breast, belly white with green and bronze bars, underside of wing with white band; eye-ring orange-red, iris red to red-brown, bill orange with black tip, feet green. Female bronze-green above, crown and nape light rufous, tail barred chestnut and black, green in centre; white below, tinged rufous on throat and flanks, barred with bronze; iris brown, bill yellow with black tip, feet brownish green. Juvenile variable, head rufous (some white-barred on crown) or barred green and white, or head and mantle rufous, back and wing-coverts barred rufous and bronze-

green, or rufous and brown, tail barred brown and rufous; throat and breast rufous with bronze bars, belly white barred with brown, white underwing band; bill black above, flesh below, feet grey. **VOICE.** A "chweek" in flight; a trill; also loud whistled twitters.

Habitat. Dense evergreen forests, broadleaf secondary forest, outside breeding season also sometimes orchards and gardens. Lowlands to 2500 m in Nepal and Myanmar, to 1800 m in Thailand, lower in winter.

Food and Feeding. Insects, feeding on ants, caterpillars, bugs. Forages mainly in tree canopy, often taking prey on the wing.

Breeding. Breeds Apr-Jul. Brood-parasitic: hosts Crimson Sunbird (*Aethopyga siparaja*) and Little Spiderhunter (*Arachnothera longirostris*) in India. Eggs whitish, blotched with light brown or reddish brown; 17 x 12 mm; identification based on egg seen to hatch and develop into juvenile of present species.

Movements. Resident or partially migratory in India, but details uncertain; nomadic and local migrant, as are other parasitic cuckoos. Summer visitor to Nepal Apr-Aug, few in Sept, and also summer visitor to Tibet, but apparently resident in Yunnan and Hainan; in Thailand, some are residents (as also in Myanmar?), but species is also recorded there more widely as a winter visitor. Probably only a winter visitor in Malay Peninsula, but reported by some to be present all year. Winters also S to Sumatra (4 records). Single record (type specimen) from Sri Lanka, presumably a vagrant.

Status and Conservation. Not globally threatened. Scarce in Nepal and probably elsewhere in NW of range; similarly scarce in Myanmar, and uncommon in Thailand. Overall situation poorly known, but species appears to be at best uncommon in any part of range, both in breeding and in wintering areas. **Bibliography.** Ali & Ripley (1981), Baker (1906-1907, 1908, 1934), Becking (1981), Cheng Tsohsin (1987), Deignan (1945), Étchécopar & Hùe (1978), Friedmann (1968), Harrison (1969b), Legge (1880), Lekagul & Round (1991), MacKinnon & Philipps (1993), van Marle & Voous (1988), Medway & Wells (1976), Meyer de Schauensee (1984), Ripley (1982), Smythies (1986), Stepanyan (1995), Yang Lan *et al.* (1995).

38. Violet Cuckoo

Chrysococcyx xanthorhynchus

French: Coucou violet

German: Amethystkuckuck

Spanish: Cucillo Violeta

Taxonomy. *Cuculus xanthorhynchus* Horsfield, 1821, Java. Asian and Australasian forms of *Chrysococcyx* sometimes placed in genus *Chalcites*. Two subspecies recognized. **Subspecies and Distribution.** *C. x. xanthorhynchus* (Horsfield, 1821) - NE India and Bangladesh E to Myanmar, Thailand and SC China (Yunnan), and S through Malay Peninsula and Indochina to Greater Sundas and SW Philippines (Palawan). *C. x. amethystinus* (Vigors, 1831) - Philippines (Basilan, Cebu, Luzon, Mindoro, Samar, Mindanao, Catanduanes).

Descriptive notes. 16 cm; 21 g. Adult male glossy violet above and on head, tail blackish with white tip, outer feathers barred; chin to upper breast bright violet, belly white with broad black, violet or green bars; eye-ring red, iris red to brown, bill yellow with orange-red base. Female greenish bronze above, crown dark brown, white markings around eye (and sometimes on forehead), central tail greenish, remainder rufous with greenish bars, outer rectrices barred black and white; breast whitish with bronze-green bars and variably washed rufous; iris brown, bill brown, feet olive-green. Juvenile barred rufous and greenish bronze above, crown bright rufous.

wing rufous and green or rufous and brown, tail barred brown and rufous, brown-barred white below, iris and bill dark brown. Male *amethystinus* glossy blue-violet, less reddish violet. VOICE. A “che-wick”, often in flight; also shrill descending trill preceded by a triple note “seer-se-seer, seeseeseeseese”.

Habitat. Secondary evergreen forests, deciduous forest, forest edge, orchards, gardens, mangroves, rubber plantations in Borneo. Lowlands and lower hill slopes to 1500 m, mostly below 700 m.

Food and Feeding. Insects, including caterpillars, flies, ants, beetles; also fruit. Creeps up and down branches, also flycatches; usually perches motionless.

Breeding. Brood-parasitic: hosts in India thought to be mainly sunbirds (*Aethopyga*) and spiderhunters (*Arachnothera*). Eggs unknown.

Movements. Resident or migratory. N populations including those in Assam and Bangladesh, appear to be migratory; S populations are resident.

Status and Conservation. Not globally threatened. Vulnerable to deforestation throughout its range. In breeding season, widespread but scarce in Myanmar, and uncommon in Thailand; reportedly not uncommon in Sumatra, but now rare in Java; not uncommon in Sarawak, and locally common in Sabah; generally uncommon in Philippines. Uncommon in winter in India S of breeding range, and apparently only vagrant to Andaman and Nicobar Is.

Bibliography. Ali & Ripley (1981), Baker (1906-1907, 1934), Becking (1981), Cheng Tsohsin (1987), Dickinson *et al.* (1991), Engelbach (1932), Étchécopar & Hùe (1978), Friedmann (1968), Gilliard (1950b), Harrison (1969b), Hellebrekers & Hoogerwerf (1967), Lekagul & Round (1991), MacKinnon & Philipps (1993), van Marle & Voous (1988), Medway & Wells (1976), Parker (1981), Parkes (1971a), Ripley (1982), Round (1988), Smythies (1981, 1986), Thewlis *et al.* (1996), Thompson *et al.* (1993).

39. Yellow-throated Cuckoo

Chrysococcyx flavigularis

French: Coucou à gorge jaune

German: Gelbkehlkuuckuck

Spanish: Cucillo Gorgigualdo

Other common names: Yellow-throated Green Cuckoo

Taxonomy. *Chrysococcyx flavigularis* Shelley, 1880, Elmina, Ghana. Birds in Cameroon, Zaire and Uganda recently described as race *parkesi* based on darker belly and undertail-coverts of a few female and young male specimens, but most appear to be indistinguishable from those in W of range. Monotypic. **Distribution.** Forest zone from Sierra Leone and Ghana through Nigeria, S Cameroon and Gabon to Zaire, SW Sudan and SW Uganda. **Descriptive notes.** 19 cm; 30 g. Adult male bronze-washed dark coppery-brown above and on neck sides, outer rectrices white with subterminal black bars; chin, throat and centre of breast bright yellow, sides of throat and breast dark green, below barred buff and greenish brown; eye-ring yellowish green, iris yellow, bill greenish yellow, feet yellow. Female lacks green and yellow on throat, face and underparts finely barred rufous and dark brown; bill black, feet dull yellow. Juvenile barred greenish and buff above. VOICE. Clear flute-like whistle of 9-12 notes on same pitch, first the longest, accelerating

and then fading away, series lasting c. 3 sec; also both sexes give 2-note whistle, second note lower, “dhuitt-tiu”. Sings all year.

Habitat. Primary forest canopy, old secondary and gallery forest; usually remains high in forest canopy, where identified by its song. Lowlands.

Food and Feeding. Insects, mainly caterpillars, also beetles; fruit.

Breeding. In Liberia, egg in Mar. Presumably brood-parasitic: hosts unknown. Broken oviduct egg pale green with blackish blotches (Liberia). **Movements.** Resident.

Status and Conservation. Not globally threatened. Rare in W Africa, but locally more common in C Africa; most records are in the Congo basin, but species occurs regularly in C Nigeria (Kagoro); uncommon in Sierra Leone, with most records from NC, in open country with patches of forest. Only one definite record in S Sudan.

Bibliography. Ash (1990), Bannerman (1953), Britton (1980a), Brosset & Érad (1986), Cheke & Walsh (1996), Christy & Clarke (1994), Dickerman (1994), Dowsett & Forbes-Watson (1993), Dyer *et al.* (1986), Elgood *et al.* (1994), Friedmann (1956, 1968, 1969), Fry *et al.* (1988), Grimes (1987), Lippens & Wille (1976), Louette (1981), Mackworth-Præd & Grant (1957, 1970), Nikolaus (1987), Short *et al.* (1990), Snow (1978), Traylor & Archer (1982).

40. Klaas's Cuckoo

Chrysococcyx klaas

French: Coucou de Klaas

German: Klaaskuckuck

Spanish: Cucillo de Klaas

Taxonomy. *Cuculus Klaas* Stephens, 1815, Cape Province. Birds from Arabia were proposed as possible race *arabicus*. Monotypic. **Distribution.** Senegal E to Sudan and Ethiopia and S to South Africa, including Bioko (Fernando Póo); possibly also in SW Arabia, where status unclear.

Descriptive notes. 18 cm; 26 g. Adult male metallic green above, green patch from back down side of neck, white streak behind eye, outer tail white; white below, flanks barred green; eye-ring green, iris dark brown, bill green, feet greenish. Female has metallic green replaced by grey-brown, this extending down sides of neck and breast, back barred green and brown, white below, finely barred brown, iris light brownish grey; some females in W Africa have male-like plumage. Juvenile barred green and buff above, wing barred; white below, all barred dull green, green bars narrower than white, iris hazel. VOICE. Two clear whistles, “mei-tjie”, the first slurred

up, the second slurred down.

Habitat. Open woodland, forest edge, thickets; in Sierra Leone, particularly common in areas of forest/savanna mosaic; nearly all records (84%) in E Africa are within 500+ mm rainfall region. Lowlands to 3000 m.

Food and Feeding. Insects, mainly caterpillars, also butterflies, bug nymphs, beetles, small Orthoptera, termites. Forages in foliage, and occasionally flycatches.

Breeding. Breeds in rains, Sept-Nov in Senegambia, Mar-Sept in Nigeria, Dec-Jun E of Rift Valley in E Africa, Oct-Feb in Malawi, during winter rains in Jul-Sept in Cape region of South Africa. Brood-parasitic: hosts small insectivorous songbirds, mainly warblers and sunbirds. Eggs variable (white, greenish white, blue), spotted with brown or rufous; 19 x 13 mm; incubation 11-12 days. Hatchling naked, skin brown, darkens to deep blackish olive, bill dark horn, iris grey-brown, gape orange; evicts host's eggs and young; nestling period 19-21 days.

Movements. Resident in equatorial areas. Seasonal migrant at higher latitudes, arriving in rains, leaving after end of rains, although some remain in non-breeding season, when silent. In N Senegal occurs only in rainy season, in Ghana mainly a wet-season visitor, in N Togo in rains, and in S Togo throughout the year. Occasional records in SW Arabia, where possibly breeds.

Status and Conservation. Not globally threatened. A widespread and generally common species; persists in residential areas where flowers are available for sunbird hosts. Although there are no breeding records from Arabia, it is thought that this cuckoo may be a rare breeding resident in the SW. N to the Tihamat.

Bibliography. Amadon (1953), Ash & Miskell (1983), Bannerman (1953), Benson & Benson (1977), Benson *et al.* (1971), Berger (1955), Bishop *et al.* (1995), Bouwman (1995), Britton (1980a), Cave & Macdonald (1955), Chapin (1954), Cheke & Walsh (1996), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Dowsett & Forbes-Watson (1993), Elgood, Fry & Dowsett (1973), Elgood, Heigham *et al.* (1994), Evans, M.I. 41. African Emerald Cuckoo

Chrysococcyx cupreus

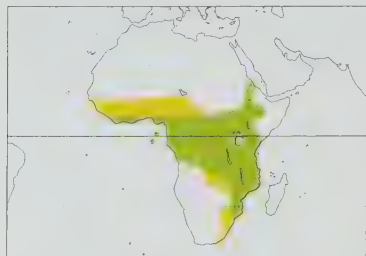

French: Coucou foliotocol

German: Smaragdckuckuck

Spanish: Cucillo Esmeralda Africano

Other common names: Emerald Cuckoo

Taxonomy. *Cuculus cupreus* Shaw, 1792, Gambia. Sometimes treated as polytypic, with races based on length of tail and wing, with tail length shorter on São Tomé, Príncipe and Pagalu (*insularum*), intermediate on Bioko (*intermedius*), longer in most of continental Africa (*cupreus*) and short in S Africa (*sharpae*), and on markings on undertail-coverts, but these traits overlap considerably between regions. Monotypic. **Distribution.** Sub-Saharan Africa from Gambia and S Senegal to S Sudan and N Ethiopia, S to N Angola and E South Africa; also Gulf of Guinea islands.

Descriptive notes. 20 cm; 38 g. Adult male brilliant iridescent green above, head and breast green, belly yellow; eye-ring blue, iris brown, bill green, slaty below, feet bluish. Female barred green and rufous above, face brownish and finely barred white, whitish below with greenish bars, breast washed buff, eye-ring bluish green, iris dark brown, bill black-tipped. Juvenile barred green and brown above, head barred green and white, below barred white and green (green bars as wide as white). **VOICE.** Song a clear 4-part slurred whistle, "hello, Ju-dy", the second note low in pitch, the last note highest.

Habitat. Forest, seasonal miombo (*Brachystegia*) woodland, savanna woodland, secondary growth, thickets, large shade trees, even in towns and suburbs, where it sings in introduced eucalypts. Occurs in lowlands in W Africa; in Kenya from lowlands to 2000 m highland forest "islands" in semi-arid regions, nearly all in 500+ mm rainfall region; in Ethiopia to 3000 m.

Food and Feeding. Insects, mainly hairy caterpillars (e.g. *Agathodes tomenis* on São Tomé), also beetle grubs, grasshoppers, butterflies, termites; some fruit, also bird eggs, snails. Forages in dense canopy foliage; usually remains high in trees.

Breeding. Breeds in rains, mainly Sept-Nov in S Africa, in long rains (when hosts breed) in Kenya, in Sept-Mar in Gabon. Brood-parasitic: hosts small songbirds, e.g. bulbuls, warblers, sunbirds (*Nectarinia*) and weavers, mainly insectivorous, though one host, Yellow-whiskered Greenbul (*Andropadus latirostris*), raises the young cuckoo on a diet of fruit. Eggs colour variable: white, pink or pale blue, usually marked with brown, or bluish grey with brown spots and blotches, or rose-red with brown cap, or rose-salmon with circle of red speckles; no evidence of mimicry of host eggs; 20 x 15 mm; female removes host's egg; incubation up to 13 days. Hatchling naked, skin pinkish yellow, darkening with age, upper mandible whitish, gape orange; evicts host's eggs and young; nestling period 18-20 days, cared for by foster parents up to 2 weeks after fledging.

Movements. Seasonal migrant in S Africa, some remaining in dry season, when silent and difficult to observe; mainly resident in E Africa; local resident or partial migrant with rains in W Africa. Resident in forest areas, and arrives with rains in gallery forests in the N savannas.

Status and Conservation. Not globally threatened. Fairly common; infrequently observed when high in dense foliage, but conspicuous when singing. Reported to be common in parts of S Africa. In late 19th century this species was common in Gambia and in Casamance, S Senegal, but is now rare in those areas; numbers decreased in Togo through hunting. In Sierra Leone, common in E but only casual elsewhere, and generally restricted to forest or areas where sufficient tall trees remain.

Bibliography. Amadon (1953), Atkinson *et al.* (1994), Bannerman (1953), Benson & Benson (1977), Benson *et al.* (1971), Berger (1955), Britton (1980a), Brosset (1976b), Brosset & Érad (1986), Cave & Macdonald (1955), Cheke & Walsh (1996), Christy & Clarke (1994), Colston & Curry-Lindahl (1986), Dechant (1996), Desfayes (1975), Dowsett & Forbes-Watson (1993), Elgood, Fry & Dowsett (1973), Elgood, Heigham *et al.* (1994), Friedmann (1956, 1966, 1968), Fry *et al.* (1988), Ginn *et al.* (1989), Goodwin (1988), Gore (1990), Grimes (1987), Jensen & Jensen (1969), Jones & Tye (1988), Lewis & Pomeroy (1989), Lippens & Wille (1976), Lockhart & Kakebecke (1992), Mackworth-Praed & Grant (1957, 1962, 1970), Maclean (1993), Moreau & Chapin (1951), de Naurois (1979, 1994), Nikolaus (1987), Oatley (1980), Pérez del Val (1996), Pinto (1983), Rowan (1983), Rutgers & Norris (1972), Ryves (1959), Short *et al.* (1990), Snow (1978), van Someren (1956), Vincent (1965), Worman (1930), Zimmerman (1972), Zimmerman *et al.* (1996).

42. Diederik Cuckoo

Chrysococcyx caprius

French: Coucou didric

German: Goldkuckuck

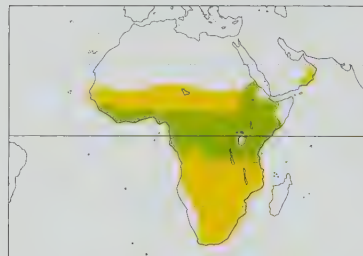

Spanish: Cuculillo Didric

Other common names: Did(e)ric Cuckoo

Taxonomy. *Cuculus caprius* Boddaert, 1783, Cape of Good Hope.

Possible shorter-winged race, *chrysoclorus*, has been described as resident in W Africa, along with long-winged birds, but short-winged individuals also occur in S Africa. Monotypic.

Distribution. Sub-Saharan Africa; also S Arabia.

Descriptive notes. 19 cm; 32 g. Adult male glossy bronze-green above, white supercilium broadest behind eye, white spots on wings and tail sides; white below, flanks barred green; eye-ring red, iris red, bill black, feet grey. Female often duller, some rufous above, throat usually washed buff, breast often lightly streaked, eye-ring brown, iris hazel-brown to grey (sometimes with dark flecks). Juvenile dull green or bright rufous (or both) above, with spots (not streaks) on breast, barred flanks, iris brown, bill red. **VOICE.** Male has clear emphatic whistle, first notes often rising in pitch, "de-dee-dee-diederik", also gives wavering "weahweahweahweah" when advertising with a caterpillar to female; female call "deah deah deah..."

Habitat. Semi-arid thorn scrub, acacia savanna, open woodlands, and edge of marshland habitat; locally also in gardens, e.g. in Douala, Cameroon; in semi-arid regions occurs around water, often near weaver colonies, where it is chased by the nesting weavers. Sea-level to c. 2000 m, generally below 1200 m.

Food and Feeding. Insects, mainly caterpillars, also grasshoppers, termites, beetles, adult Lepidoptera, eggs of host birds; seeds. Forages mostly in canopy; may also seek food on ground, e.g. in W Africa.

Breeding. Breeds with rains, lays Aug-Oct in N Senegal, Aug-Nov in Sierra Leone, Sept-Oct in W Mali, Mar-Jul in coastal districts of Ghana, mainly Apr-Sept in N Nigeria, Oct-Apr in Malawi, in both short rains (Apr-May) and long rains (Nov-Jan) at semi-arid L Baringo in Kenya, in South Africa from late Oct to mid Jan in E Cape. Brood-parasitic: hosts mainly weavers (*Ploceus*), bishops (*Euplectes*) and sparrows (*Passer*), others include wagtails (*Motacilla*); more than one female may use a single tree in a weaver colony. Eggs variable, white, greenish or blue, unspotted or spotted, often match colour and pattern of host's; 21 x 15 mm; incubation 12 days. Hatchling naked, skin pink, darkening to blackish, bill orange to red, gape red; when 2 days old evicts host's eggs and young; fledges in 19-21 days, remaining with foster parents for 3 more weeks.

Movements. Resident in low-latitude tropics; also an intra-African migrant, seasonal in N and S of range. The long-winged individuals in W Africa are possibly non-breeding migrants from S Africa, but no ringing recoveries or other positive evidence of two morphologically distinct populations are known. In S Arabia, appears as a summer visitor, e.g. in Oman May-Oct. In N Senegal a seasonal visitor in the rains, but present all year in the S; in Gambia Jun-Nov; in Ghana occurs mainly in wet season, a seasonal visitor in the N; in N Nigeria present during rains May-Oct, then migrates S for the dry season; in Sudan a breeding visitor in rains, except resident in extreme S; in Kenya a wet-season visitor in dry areas; in Malawi, most are present and sing Oct-Mar, though a few are observed in other months as well. In Sierra Leone, after breeding many birds withdraw to forest canopy where recorded Nov-Apr, and from late Feb to late Mar species hardly recorded outside forest; local movements probably correlated with caterpillar abundance. In Gabon it appears in savannas as a non-breeding visitor from the Sahel in Jan-Feb, and is a local resident at all seasons around weaver colonies. Accidental in Cyprus and Israel.

Status and Conservation. Not globally threatened. Generally common throughout much of its expansive range in fair variety of habitats, often quite heavily humanized; frequently fairly conspicuous due to its characteristic voice, and seen especially around colonial nesting ploceids.

Bibliography. Amadon (1953), Ash & Miskell (1983), Bannerman (1953), Benson & Benson (1977), Benson & Serventy (1957), Benson *et al.* (1971), Berger (1955), Bouwman (1995), Bowen (1983a), Britton (1980a), Brooke & Borrett (1972), Bruggers & Bortoli (1979), Cave & Macdonald (1955), Chalton (1976, 1991), Cheke & Walsh (1996), Christy & Clarke (1994), Clancey (1990), Coetsee (1982), Colebrook-Robjent (1975, 1977, 1980, 1984), Colston & Curry-Lindahl (1986), Cramp (1985), Dowsett & Forbes-Watson (1993), Elgood, Fry & Dowsett (1973), Elgood, Heigham *et al.* (1994), Evans, M.I. (1987), Snow (1978), Zimmerman (1972), Zimmerman *et al.* (1996).

Genus *RHAMPHOMANTIS* Salvadori, 1878

43. Long-billed Cuckoo

Rhamphomantis megarhynchus

French: Coucou à long bec **German:** Langschnabelkuckuck **Spanish:** Cucillo Piquilargo
Other common names: Little Long-billed Cuckoo

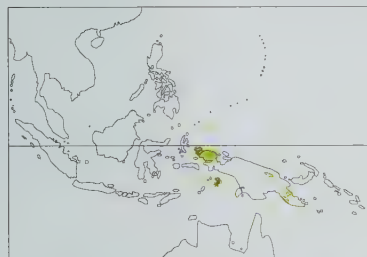

Taxonomy. *Cuculus megarhynchus* G. R. Gray, 1858, Aru Islands.

Race *sanfordi* known only from one specimen, claimed to be an adult female; in type description, this bird would appear rather similar to juveniles of nominate race; as juvenile and subadult plumages of this species have only very recently begun to be understood, validity of race *sanfordi* probably requires reassessment. Two subspecies recognized.

Subspecies and Distribution.

R. m. megarhynchus (G. R. Gray, 1858) - New Guinea (Vogelkop and interior of N coast E to Kumusi R) and Aru Is.

R. m. sanfordi Stresemann & Paludan, 1932 - Waigeo I.

Descriptive notes. 18 cm; 31 g. Adult male dark brown above, head black, dull greyish brown below; eye-ring and iris red, long bill black with drooping tip. Female dark cinnamon above, head dark grey-brown; breast and belly rufous buff and finely barred, lower breast cinnamon; iris dark brown with narrow cream outer ring. Juvenile cinnamon above, face pale grey and brown, eye-ring dark, iris dark brown. Race *sanfordi* female said to have breast greyer, contrasting with rufous belly; male undescribed. Voice. Loud, distinct trill, a descending series of evenly spaced notes, lasting 4 sec. and repeated at 5-sec intervals.

Habitat. Tall forests (c. 70 m high) and openings in them; occurs in lowlands.

Food and Feeding. Insects, mainly caterpillars, also flying ants. Gleans prey from foliage, branches or bark.

Breeding. Unknown. Female with egg in oviduct ready to lay in Sept.

Movements. Unknown.

Status and Conservation. Not globally threatened. Species is generally rare and local; because of its restricted range, it has in the past been considered near-threatened. Extensive research required on biology, ecology and population sizes of this unusual species.

Bibliography. Andrew (1992), Anon. (1994a), Beehler, Burg *et al.* (1994), Beehler, Pratt & Zimmerman (1986), Coates (1985), Finch (1978, 1979a), Jepson (1997), Rand & Gilliard (1967), Ripley (1964), Stein (1936).

Genus *SURNICULUS* Lesson, 1830

44. Asian Drongo-cuckoo

Surniculus lugubris

French: Coucou surnicou d'Asie **German:** Drongokuckuck **Spanish:** Cucillo-drongo Asiático
Other common names: Drongo Cuckoo (together with *S. velutinus*)

Taxonomy. *Cuculus lugubris* Horsfield, 1821, Java.

Forms a superspecies with *S. velutinus*, with which commonly considered conspecific, but song and juvenile plumage are distinct. Four subspecies recognized.

Subspecies and Distribution.

S. l. dicruroides (Hodgson, 1839) - Punjab and lower Himalayas E through Nepal to Assam and Manipur, and from SC China (Sichuan, Yunnan, Fujian, Hainan) S through Myanmar and Thailand to Indochina; winters S to Malaysia, Sumatra (and Nias) and Java.

S. l. lugubris (Horsfield, 1821) - SW coast of India (S of Goa), Sri Lanka, Java and Bali.

S. l. brachyurus Stresemann, 1913 - Malaysia, Sumatra and Bangka, Borneo and SW Philippines (Palawan, Balabac, Calauit).

S. l. musschenbroeki A. B. Meyer, 1878 - Sulawesi and Butung to Bacan and Halmahera (N Moluccas).

Descriptive notes. 25 cm; 35 g. Adult glossy black, tail square or slightly forked, white leggings, white bands on undertail-coverts, white bar on underwing; skin around eye blackish, iris brown, bill black, feet dark grey. Juvenile dull black, with white spots on head, wings and breast. Race *dicruroides* larger; *brachyurus* shorter-tailed; *musschenbroeki* velvet-purple on head, tail square. VOICE. Loud clear whistles rising up the scale, "one, two, three, four, five, six"; also a shrill crescendo; often calls at night. In Sulawesi, song has 8 notes in rapid succession and equal pitch, then a pause before a new series. In Bacan, 5-8 notes, usually 6. In Halmahera, reported as slightly different in quality from song of Malaysian birds, with series of 6-8 notes, occasionally as many as 12; a song recorded on Halmahera (range of *musschenbroeki*) was like that of *S. velutinus* of Philippines, but juvenile collected on Halmahera has plumage as other juvenile *S.*

velutinus of Philippines, but juvenile collected on Halmahera has plumage as other juvenile *S.*

lugubris. Also a "crescendo" call, a rapidly trilled series of rising notes ending with c. 3 descending notes, with harsh tonal quality like a call of *Cuculus clamosus*.

Habitat. Forests and scrub, forest edge and clearings, open forests and bamboo jungle in Myanmar, interior of dry forests in Sri Lanka; occasionally gardens, mangroves. Mainly lowlands, but in Nepal to 1500 m, occasionally 2000 m, in Yunnan to 2100 m; in Myanmar and Thailand to 1200 m, in Peninsular Malaysia to 800 m, in Sarawak to 1200 m, in Sulawesi at 300 m and 500 m, on Halmahera at 250 m.

Food and Feeding. Insects, caterpillars (hairy and hairless; Pieridae, Lasiocampidae, Limadodidae), other soft insects, spiders; sometimes fruit, especially figs. Forages in foliage canopy, also perches on charred stumps and saplings in recently burned clearings.

Breeding. Breeds Jun in Nepal, Mar-Oct in N India, Jan-March in Kerala, Dec-May in Sri Lanka, based on song, enlarged gonads and breeding of hosts. Brood-parasitic, with hosts mainly babblers: in India, Nepal *Fulvetta (Alcippe nipalensis)* and Dark-fronted Babbler (*Rhopocichla atriceps*), also fork-tails (*Enicurus*), Sooty-headed Bulbul (*Pycnonotus aurigaster*), ioras (*Aegintha*), shrikes (*Lanius*) and Striated Warbler (*Megalurus palustris*); in Sri Lanka *R. atriceps*; in Malaysia, Striped Tit-babbler (*Macronous gularis*) and Horsfield's Babbler (*Malaccocincla sepiarium*); in Java, *M. sepiarium*, Grey-cheeked Tit-babbler (*Macronous flavicollis*) and Chestnut-chested Babbler (*Stachyris melanothorax*); in Borneo, Chestnut-winged Babbler (*Stachyris erythroptera*). *Macronous gularis* mob this cuckoo, apparently recognizing it as their brood parasite; no evidence that drongos (*Dicrurus*) are used as hosts, even though Hair-crested Drongo (*D. hottentottus*) seen to call and chase a cuckoo (drongos are aggressive, and chase many other species). Eggs white with fine purple blotches in Borneo, similar oviduct egg in Nepal; in Java, pale salmon-pink with brownish, purplish or grey markings; 20 x 15.5 mm. Nestling has mouth-lining bright red, feet vinaceous; evicts host's eggs and chicks.

Movements. Resident, seasonally migratory and nomadic, appearing with monsoon rains. In Nepal, a summer visitor Apr-Nov. Northernmost race *dicruroides* winters S to Malaysia and Greater Sundas; accidental Japan.

Status and Conservation. Not globally threatened. Like many other forest birds, this species is subject to the effects of widespread habitat destruction throughout its range. In Myanmar, sparingly distributed throughout, while generally uncommon in Thailand and Greater Sundas. In Malaysia, fairly common at Taman Negara; in Singapore it occurs as a rare resident and commoner migrant in secondary forest, particularly Catchment Forest and Bukit Timah Nature Reserve. In Sri Lanka, rare in low-country dry zone. Widespread in Sulawesi, and now considered to be not uncommon to rather common.

Bibliography. Ali & Ripley (1981), Ali & Whistler (1937), Ali *et al.* (1996), Andrew & Holmes (1990), Baker (1906-1907, 1934), Becking (1981), Biswas (1960), Brazil (1991), Cheng Tsohsin (1987), Coates & Bishop (1997), Cranbrook & Wells (1981), Deignan (1945), Dickinson *et al.* (1991), Duckworth (1997), Etchécopar & Hùe (1978), Harrison (1969b), Harvey (1990), Hellebrekers & Hoogerwerf (1967), Lambert (1994b), Lambert & Young (1989), Legge (1880), Lekagul & Round (1991), MacKinnon & Philipps (1993), Madoc (1976), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986), Osmaston (1916), Phillips (1978), Ripley (1944, 1946, 1982), Roberts, T.J. (1991), Smythies (1960, 1981, 1986), Sody (1989), Stepanyan (1995), Stresemann (1913a), Wait (1925), Watling (1983), Wells & Medway (1976), Whistler (1944), White & Bruce (1986).

45. Philippine Drongo-cuckoo

Surniculus velutinus

French: Coucou surnicou des Philippines **Spanish:** Cucillo-drongo Filipino
German: Philippinen-Drongokuckuck

Taxonomy. *Surniculus velutinus* Sharpe, 1877, Malamaui, Philippines.

Forms a superspecies with *S. lugubris*, and commonly considered conspecific, but song and juvenile plumage are distinct. Monotypic.

Distribution. Philippines and Sulu Is.

Descriptive notes. 23 cm; 36 g. Adult blackish, head and mantle velvety (not glossy, as in *S. lugubris*), wings and tail glossy purplish, blue or green, tail square; white bar on underside of wing; white leggings; iris brown, bill black, feet dark grey. Juvenile unmarked rusty-brown. VOICE. Song a series of 8-10 whistles, longer, more notes and less rise in pitch than in *S. lugubris*.

Habitat. Primary forest, secondary forest, mixed bamboo woodland. In Philippines, from sea-level to 1000 m.

Food and Feeding. Insects. Forages in forest canopy.

Breeding. Unknown.

Movements. Resident.

Status and Conservation. Not globally threatened. Although this species is fairly common in primary forest in the Philippines, this habitat is being rapidly removed by logging operations; to date, species has shown only limited capability of adapting to degraded habitat, so long-term effects of logging will surely prove markedly detrimental to the species.

Bibliography. Baker (1919), Delacour & Mayr (1946), Dickinson *et al.* (1991), DuPont (1971), Gilliard (1950b), Greenway (1978), Hachisuka (1934), Meyer de Schauensee & DuPont (1962), Parkes (1973), Rabor (1938), Rand & Rabor (1960), Ripley & Rabor (1958), Salomonsen (1953).

Genus *CALIECHTHRUS* Cabanis & Heine, 1863

46. White-crowned Koel

Caliechthrus leucolophus

French: Coucou à calotte blanche **German:** Weißscheitelkoel **Spanish:** Koel Coroniblanco

Taxonomy. *Cuculus leucolophus* S. Müller, 1840, Lobo Bay, New Guinea. Monotypic.

Distribution. New Guinea and Salawati.

in canopy.

Breeding. Unknown.

Movements. Unknown.

Status and Conservation. Not globally threatened. Little information available on relative abundance; frequently recorded at Varirata National Park, near Port Moresby. Extensive research required on biology, ecology and population sizes of this unusual species.

Bibliography. Andrew (1992), Bailey (1992a), Beehler (1978b), Beehler, Burg *et al.* (1994), Beehler, Pratt & Zimmerman (1986), Burrows (1993), Coates (1985), Diamond (1972a), Eastwood (1995b), Gregory (1995a, 1995b), Hartert (1930), Jepson (1997), Mayr & Rand (1937), Rand & Gilliard (1967).

Descriptive notes. 33 cm; 117 g. Adult black, white stripe down crown, undertail-coverts barred white, tail tipped white; iris dark brown, bill black, feet dark grey. Juvenile black, barred white below, plumage softer. Voice. Loud, mournful repetitive song of 3 or 4 descending whistles, each series higher in pitch and more insistent. Also a call of 3-4 clear notes on same pitch, a ringing and laughing "cuo-cuo-cuo-cuo", and a single burry downslurred "whurr".

Habitat. Forest, mainly canopy in hilly country. Sea-level to 1500 m.

Food and Feeding. Mainly insects, including caterpillars, other arthropods; also fruit. Feeds

times recognized subspecifically (*dolosa*), being small and female having large rufous spots above, but overlap occurs with *malayana* of Malaysia and Sumatra. Seventeen subspecies recognized.

Subspecies and Distribution.

E. s. scolopacea (Linnaeus, 1758) - Nepal, Pakistan and India to Sri Lanka, Laccadives and Maldives.

E. s. chinensis Cabanis & Heine, 1863 - S China and Indochina; winters S to Borneo.

E. s. harterti Ingram, 1912 - Hainan.

E. s. malayana Cabanis & Heine, 1863 - E India and Bangladesh, through Myanmar, Thailand and Peninsular Malaysia to Andaman and Nicobar Is, Sumatra and Bangka, Borneo and Lesser Sundaes (Lombok, Sumbawa, Flores).

E. s. simalurensis Junge, 1936 - Simeulue and off-lying islands of Kokos and Babi (off NW Sumatra).

E. s. frater McGregor, 1904 - NE Philippines (Calayan and Fuga).

E. s. mindanensis (Linnaeus, 1766) - Talaud and Sangihe Is to Philippines (including Palawan).

E. s. melanorhyncha S. Müller, 1843 - Sulawesi.

E. s. facialis Wallace, 1863 - Sula Is.

E. s. corvina Stresemann, 1931 - N Moluccas (Morotai, Halmahera, Ternate, Tidore, Moti, Bacan).

E. s. orientalis (Linnaeus, 1766) - C Moluccas (Buru, Manipa, Kelang, Seram, Ambon, Tujuh, Watubela).

E. s. picata S. Müller, 1843 - Kai Is and Sumba to Timor and Roma.

E. s. rufiventer (Lesson, 1830) - New Guinea.

E. s. salvadorii Hartert, 1900 - Bismarck Archipelago.

E. s. alberti Rothschild & Hartert, 1907 - Solomon Is.

E. s. subcyanocephala Mathews, 1912 - N Australia E to W Queensland; migrant to New Guinea.

E. s. cyanocephala (Latham, 1801) - N Queensland to New South Wales.

Descriptive notes. 39-46 cm; male 215 g, female 234 g (*cyanocephala*), 230 g (Asian forms), 254-327 g (Indonesian and New Guinea forms). Adult male *scolopacea* glossy black, iris red, bill light green, feet grey. Female dark brown above with many white spots and bars, crown rufous with whitish streaks, tail barred black and brown; white below, throat spotted, breast and belly barred blackish brown. Juvenile like adult, buff tipping on breast and abdomen, female darker above with blackish head and breast, iris brown, bill black. Races differ mostly in plumage of females, and populations vary in extent of a distinct subadult

plumage. S Asian forms: *chinensis* larger, female with no rufous on crown; *harterti* smaller, longer-billed than *chinensis*; female *malayana* has pale areas washed rufous; *simalurensis* smaller, female with large rufous spots above; *mindanensis* with light areas more rufous, ventral barring narrower than *malayana*; *frater* similar, but larger; *corvina* juvenile smoky-black; female *orientalis* fewer and larger rufous spots above, below rich rufous with little or no barring, throat black or with black patches, bill pale grey, juvenile rufous-buff. Indonesian and New Guinea forms: *melanorhyncha* male with blue-violet gloss, bill black, iris red, female with red iris, pale malar streak, dark bill and polymorphic (like male but gloss more blue-green; or black-barred rusty-fawn below with throat and throat blackish or grey; or barred rufous and black above, buff with blackish bars below), juvenile all black or like black-and-buff female but with head to throat black; *picata* female variable (throat black, or variegated black and ochre, or two broad malar stripes separated by rufous stripe, spots and bars on back, wings and tail brownish, irregular thick black bars below); *rufiventer* smaller, female heavily spotted and barred rufous and black above, head and throat mainly rufous, underparts buff with fine dark barring; *salvadorii* larger than *rufiventer*, female markings similar (spots on lesser coverts whitish), below buffy-white with narrow black bars, bill slaty-blue; *alberti* much smaller, female buffy. Australian forms: *cyanocephala* male bill blue-grey to horn, female with black crown and face heavily streaked rufous, white stripe below eye, black throat sides, whitish below with fine blackish bars, iris red, bill light green, juvenile similar to female but rufous-crowned, throat buff to black, white to buff below with fine dark bars, iris brown, bill horn; *subcyanocephala* smaller, female with plain black crown. Voice. Loud and noisy; calls early, starting before dawn. Thailand: loud "ko-el" with stress on second note, also a bubbling "kwow kwow-kwov-kwov". Indonesia: loud shriek, "ko-el" or "kow-wow", emphasis on second syllable, a series of 5-10 phrases rising in tempo, pitch and loudness, day and night, also loud ringing "tweep" repeated 1-8 times; female gives shrill "kik-kik-kik-kik". New Guinea: (1) series of slurred notes rising in pitch, (2) rapid series of paired notes, rising then levelling in pitch; alarm a loud staccato "week week week WEEK...", female a loud "piip piip piip piip". Sulawesi: common call "kuow", also variety of loud ringing calls, frequently given before dawn. Solomon Is: 2 loud whistles, the second higher, "wo-wee", heard only at night. Australia: male a loud "kooel", a rising "quoy-quoy-quoy-quoy", a falsetto "quodel-quodel-quodel", and a rising "weir-weir-weir-weir!", female a shrill 4-note piping.

Habitat. Open forest, monsoon forest, edge and scrub, riverside scrub, plantations, orchards, gardens in towns and near human habitations, especially around figs (*Ficus*) and other fruiting trees, and mangroves. Mainly in lowlands: sea-level to 1200 m in SE Asia, to c. 1370 m (occasionally to 1800 m) in Nepal, to 1500 m in Sulawesi, to 1000 m in Australia.

Food and Feeding. Fruit, including figs (*Ficus*), berries of *Morus*, *Zizyphus*, papaya (*Carica papaya*) and other fruiting trees, e.g. Brazilian cherries (*Eugenia uniflora*), and tamarinds (*Tamarindus indica*), *Sterculia foetida*, and oil palm nuts and other palms (*Archontophoenix alexandrae*); also few insects (grasshoppers, caterpillars), snails, flower nectar. Arboreal, feeds in tree canopy; flight swift and direct. Nestlings are raised not only by insect-eating hosts but also by fruit-eating species such as figbirds (*Sphecotheres*), which feed both fruit and insects to young.

Breeding. Breeds Mar-Aug (mainly May-Jun) in India, Apr-Aug in Sri Lanka, Feb-Apr in Malaysia, and in Australia Oct-Feb in Queensland, Nov-Feb in Kimberley Division, Dec-Feb in Northern Territory. Brood-parasitic: hosts in India are House Crow (*Corvus splendens*) and Jungle Crow (*C. macrorhynchos*); in Peninsular Malaysia lays in nests of *C. macrorhynchos*; in Java and Sulawesi also of Slender-billed Crow (*C. enca*); in Sulawesi also parasitizes Sulawesi Crested Mya (*Basilornis celebensis*); in Greater Sundaes crows, drongos (*Dicrurus*) and orioles (*Oriolus*); on Palawan, Hill Mya (*Gracula religiosa*); in Australia large honeyeaters, including Noisy Friarbird (*Philemon carunculatus*) and Red Wattlebird (*Anthochaera carunculata*), also Magpie-larks (*Grallina cyanoleuca*), Olive-backed Oriole (*Oriolus sagittatus*) and Figbird (*Sphecotheres viridis*). Male may distract crow from its nest, allowing female to lay in it. Eggs in India grey-blue with small brown or black spots, like *Corvus* eggs but smaller, 31 x 23 mm; in Sulawesi (where all three forms of female breed) pink, spotted, 39 x 24 mm; in Australia salmon-pink, marbled reddish and violet-grey at large end, 34 x 24 mm. In Australia, 1 egg/host nest (more than one in India), incubation 13-14 days; hatchling (*cyanocephala*) naked, mouth-lining bright orange-pink; evicts host's eggs and young; fledges in 19-28 days, fed by hosts for another 2-3 weeks. In India, shorter incubation period than crows (13-14 days, against 16-20) allows cuckoo egg to hatch first, nestlings do not evict, but decrease host's success; adult female cuckoos seen to feed fledged juveniles.

Genus *MICRODYNAMIS* Salvadori, 1878

47. Dwarf Koel

Microdynamis parva

French: Coucou à tête noire

German: Schwarzkappenkuckuck

Spanish: Koel Enano

Other common names: Black-capped Koel

Taxonomy. *Eudynamis* [sic] *parva* Salvadori, 1875, Tidore; error = New Guinea.

Two subspecies recognized.

Subspecies and Distribution.

M. p. griseusens Mayr & Rand, 1936 - N New Guinea between Humboldt Bay and Kumusi R.

M. p. parva (Salvadori, 1875) - lowland forests of rest of New Guinea, and D'Entrecasteaux Is.

Descriptive notes. 20 cm; 43 g. Adult male brown above, crown and malar streak glossy black, white stripe below eye, underparts rich buff to buffy-white; iris red, bill black. Female brown, whitish stripe below eye, throat grey, iris red or hazel, feet blue-grey to black. Immature male has charcoal-grey throat stripe, brown crown. Juvenile like adult female, back feathers slightly barred (buff tip, blackish subterminal, brown base), outer webs of wing indistinctly barred rufous and dark brown, underparts indistinctly barred light and dark brown, rectrices edged rufous, eye-stripe distinct. Race *griseusens* much greyer above and below. Voice.

One song medium to high pitch, series of resonant upslurred whistled notes, "oouei touei touei ...", 1/ sec; another a rapid series of downslurred notes, rising in pitch and levelling at end.

Habitat. Forest. Lowlands to 1450 m.

Food and Feeding. Fruit.

Breeding. Details unknown. Courtship feeding recorded.

Movements. Apparently resident.

Status and Conservation. Not globally threatened. Widespread, and common to fairly common within its range, but poorly known. Extensive research required on biology, ecology and population sizes of this distinctive species.

Bibliography. Andrew (1992), Anon. (1994a), Austin & Kuroda (1953), Bailey (1992a), Beehler (1978b), Beehler, Burg *et al.* (1994), Beehler, Pratt & Zimmerman (1986), Coates (1985), Diamond (1972a), Eastwood (1995b), Fabbro (1995), Gregory (1995a, 1995b), Hartert (1930), Jepson (1997), Mayr (1936b, 1944a), Rand & Gilliard (1967).

Genus *EUDYNAMIS* Vigors & Horsfield, 1827

48. Common Koel

Eudynamis scolopacea

French: Coucou koël

German: Indischer Koel

Spanish: Koel Común

Other common names: Asian Koel (*scolopacea* group), Black-billed Koel (*melanorhyncha*); Australian/Blue-headed Koel (*cyanocephala* group)

Taxonomy. *Cuculus scolopaceus* Linnaeus, 1758, Malabar.

Genus name sometimes incorrectly spelt *Eudynamis*. Australian birds are sometimes treated as a separate species (*E. cyanocephala*), and black-billed populations of Sulawesi to Moluccas and New Guinea as another (*E. melanorhyncha*); while both *rufiventer* and *subcyanocephala* are present in New Guinea, however, they are not known to breed sympatrically as two distinct species; and two forms (*orientalis*, ?*cyanocephala*) occur on Seram, but it is unknown if both breed there; songs and calls appear to be similar for all forms throughout their collective range. Birds on Andaman and Nicobar Is are some-

Movements. Resident or makes irregular movements. Resident in tropical areas, nomadic and local migrant in temperate N parts of range; partial migrant in Nepal. Race *chinensis* migrates to Borneo. In S Myanmar, abundant March-July and apparently absent Aug-Nov. Australian populations migratory, many leave after breeding season; *cynocephala* spends austral winter in Indonesia, *subcynocephalus* in New Guinea. In Andaman and Nicobar Is, populations are variable in plumage, females ranging from rufous-crowned to no rufous on head, which suggests repeated immigration of birds from both India and Malay Peninsula. Irregular in Taiwan; vagrant to Oman.

Status and Conservation. Not globally threatened. A widespread species with range extending to remote islands in Indian Ocean, e.g. Maldives and Laccadives. Common through much of range, from Nepal and India to Myanmar, Thailand and Malaysia at least, but less common in Greater Sundas. Common also in Andaman and Nicobar Is.

Bibliography. (1914, 1940), Stresemann, V. & Stresemann (1961), Subrahmanyam & Krishnamoorthy (1980), Watling (1983), Webb (1997), White & Bruce (1986).

49. Long-tailed Koel

Eudynamis taitensis

French: Coucou de Nouvelle-Zélande **German:** Langschwanzkoel **Spanish:** Koel Colilargo

Taxonomy. *Cuculus taitensis* Sparrman, 1787, Tahiti. Formerly placed in monotypic genus *Urodynamis*. Current genus name sometimes incorrectly spelt *Eudynamis*. Monotypic.

Distribution. Breeds in New Zealand, Great and Little Barrier, Kapiti, Stewart and Chatham Is, and also Kermadecs. Migrates to Oceania, occurring from Palau, Carolines and Marshalls through Fiji, Tonga and Samoa to Cook, Society, Austral, Marquesas and Pitcairn Is; also Bismarck Archipelago, Solomons, Vanuatu, Norfolk I, Lord Howe I and elsewhere in SW Pacific.

Descriptive notes. 38-42 cm; 120 g. Adult male long-tailed, entirely rufous-barred brown above, head blackish with rufous streaks, white streak above eye; below, white to rufous with black streaks; iris yellow, bill yellow-horn, nostril slit-like. Some birds more rufous, typically females. Juvenile brown with white spots above, tail barred whitish, buff with black streaks below. VOICE. Whistled "ouit-ouit", also a magpie-like chatter and loud shrieks; sometimes several males call in an apparent social group or lek.

Habitat. Forest, scrub.

Food and Feeding. Insects, also crabs, lizards, eggs, nestling birds; preys on nestlings even

when in non-breeding area (Norfolk I).

Breeding. Breeding season Nov-Dec. Brood-parasitic: hosts songbirds, including Yellowhead (*Mohoua novaeseelandiae*), Whitehead (*M. albicilla*) and Brown Creeper (*Finschia novaeseelandiae*); potential hosts that nest early escape parasitization. Eggs whitish, marked with purplish brown and grey; 23.5 x 17 mm. Nestlings evict eggs and young; nestling period c. 21 days; fed for at least 2 weeks after fledging, sometimes attracting and fed by adults other than foster parents that reared them.

Movements. Long-distance migrant, moving seasonally from New Zealand to Melanesia, Micronesia and (mainly) Polynesia, where remains May-Sept; resident on Raoul (Kermadecs). Adults arrive in breeding area in Oct and depart in Jan or Feb. Migrates at night, giving loud calls in flight. Immatures remain in their tropical non-breeding areas, and do not return to New Zealand to breed until their 2nd year.

Status and Conservation. Not globally threatened. Populations of present species are decreasing in numbers with the loss of forest breeding habitats and also, in tandem, the reduction in populations of its host species. Situation requires close monitoring.

Bibliography. Baker (1951), Beehler *et al.* (1986), Blackburn (1968), Bogert (1937), Bregulla (1992), Chambers (1989), Christidis & Boles (1994), Clunie (1984), Coates (1985), Cunningham (1949, 1966), Dow (1972), Ellis *et al.* (1990), Engbring & Ramsey (1989), Falla *et al.* (1981), Gill (1980b), Hannecart & Létocart (1983), Hermes (1985),

Holyoak (1980), Holyoak & Thibault (1984), Kinsky (1957), Lacan & Mougín (1974), Mayr (1944a), McLean (1982, 1985, 1988), McLean & Waas (1987), Muse & Muse (1982), Oliver (1974), Pratt *et al.* (1987), Reed (1980a), Robertson (1985), Schodde *et al.* (1983), Sparrow (1984), St. Paul (1976), Stidolph (1949), Stresemann, E. & Stresemann (1966, 1969), Stresemann, V. & Stresemann (1961), Thibault & Rives (1988).

Genus *SCYTHROPS* Latham, 1790

50. Channel-billed Cuckoo

Scythrops novaehollandiae

French: Coucou présageur **German:** Fratzenkuckuck **Spanish:** Cuco Tucán

Taxonomy. *Scythrops novae Hollandiae* Latham, 1790, New South Wales. Monotypic.

Distribution. Breeds in Sulawesi, Buru and Flores, and N & E Australia; rarely occurs in Tasmania. Winters in Moluccas, Lesser Sundas, Aru Is, New Guinea and Bismarck Archipelago.

Descriptive notes. 60 cm; male 604 g, female 623 g. The largest brood-parasitic bird. Adult grey above with black spots, head grey, tail grey with subterminal black band and white tip; light grey below, flanks barred; bill huge, usually described as pale grey, but in fact bicoloured with extensive dark grey base and pale tip; bare skin around eye reddish, iris red, feet grey. Juvenile with head and neck buff, large buff spots on wing, bill dark grey. Distinctive "Southern Cross" silhouette in flight; flies with slow and regular wingbeats. VOICE. Loud, raucous, repeated hoarse "gaak", also a rapidly repeated high nasal series, and a bubbling trumpeting.

Habitat. Canopy trees at edge of forest or along river, other open woodlands with tall trees and especially figs (*Ficus*), near coast inland from mangroves; occurs mainly in subhumid and semi-arid regions, also on coastal islands; scarce and patchy in arid zone. Lowlands.

Food and Feeding. Fruit, especially figs; also insects, including stick insects, beetles and locusts. Young in nest of currawongs (*Strepera*) are reared on fruit, young in nests of crows (*Corvus*) are often fed carrion.

Breeding. Breeds Feb-Jun in N Sulawesi, Oct-Nov in SE Australia, Nov-Jan in Kimberley Division, Oct-Jan in Queensland. Breeding male presents a large insect to female, then mates with her. Brood-parasitic, with all hosts large passerines, half size to same size as the cuckoo (mean size ranges 39-61 cm): Jungle Crow (*Corvus macrorhynchos*) and Flores Crow (*C. florensis*) in Flores; Slender-billed Crow (*C. enca*) in Sulawesi; Torresian Crow (*C. orru*) and other corvids, Pied Currawong (*Strepera graculina*), butcherbirds (*Cracticus*), Australian Magpie (*Gymnorhina tibicen*) and Magpie Lark (*Grallina cyanoleuca*) in Australia. Eggs dull white, blotched reddish or brown, 48 x 32 mm, 41 x 29 mm, similar to those of *Strepera graculina*; lays 1-5 eggs/nest (2+ in 52% of parasitized nests), often removes, cracks or dents host egg when laying; incubation period unknown. Hatchling naked, skin bronze, mouth pinkish red; unknown if eviction practised, host's chicks usually disappear from nest, cuckoo may outgrow and crowd out host's young; more than one cuckoo may fledge from a nest, sometimes young crows fledge also; fledges in 17-24 days. Fledgling's begging calls like those of host, but louder and more raucous. A captured crow-reared fledgling remained with its human "fosterer" for 30 days, flying free and returning to be fed.

Movements. Migratory and seasonal in Australia, where appears first on N coast; passage migrant through Torres Strait. Occurs in Northern Territory Oct-Apr. Rare in Queensland in Sept-Apr, though numbers winter in N Cape York Peninsula and Torres Strait region. Occurs in New Guinea in all months, but is not known to breed there; these involve mainly non-breeding birds from Australia. Vagrant New Zealand and New Caledonia.

Status and Conservation. Not globally threatened. Uncommon in much of its range in Australia, and scarce in Northern Territory. Abundant in New Britain in winter. Noisy and conspicuous in Dumoga Valley, N Sulawesi, Feb-Jun, but rare or absent at other times.

Bibliography. Barnes (1994), Beddard (1898), Beehler *et al.* (1986), Beruldsen (1980), Blakers *et al.* (1984), Brooker & Brooker (1989a), Coates (1985), Coates & Bishop (1997), Frauca (1967), Gilliard & LeCroy (1967a), Goddard & Marchant (1983), Hall (1974), Hansen (1976), Johnson (1983), Larkins (1994a, 1994b), McAllan (1995), Noske (1994), Ottow & Verheijen (1969), Rand & Gilliard (1967), Rose (1997a), Rozendaal & Dekker (1989), Rutgers & Norris (1972), Salter (1978), Schönwetter (1967), Storr (1977, 1980, 1984b), Strahan (1994), Stresemann (1940), Watling (1983), White & Bruce (1986), Wood & Wood (1991).

Subfamily PHAENICOPHAEINAE

Tribe PHAENICOPHAEINI

Genus *CEUTHMOCHARES*

Cabanis & Heine, 1863

51. Yellowbill

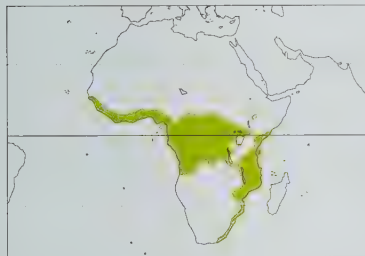

Ceuthmochares aereus

French: Malcoha à bec jaune **German:** Erzkuckuck **Spanish:** Malcoha Africano
Other common names: Green Malkoha/Coucal

Taxonomy. *Cuculus aereus* Vieillot, 1817, Malembo, Cabinda (Angola). Three subspecies recognized.

Subspecies and Distribution.

C. a. flavirostris (Swainson, 1837) - Gambia to Nigeria, W of R Niger.
C. a. aereus (Vieillot, 1817) - Nigeria and Bioko (Fernando Póo) to S Sudan and W Kenya, and S through Zaire to Angola and N Zambia.
C. a. australis Sharpe, 1873 - lowlands from Ethiopia and Kenya to Tanzania (including coastal islands), Malawi, Mozambique and coastal E South Africa.

Descriptive notes. 33 cm; 66 g. Adult of race *australis* green-glossed grey above, grey washed olive-buff below; bare skin around eye green to blue, iris red or brown, bill yellow (base of culmen black), feet black, soles white. Juvenile darker, less glossy, head grey, more grey below, iris brown, bill dark. Race *aereus* smaller, crown and nape dark grey, upperparts glossed blue, grey below; *flavirostris* glossed violet above. **Voice.** Song consists of a series of high notes descending in pitch and staccato, or increasing in tempo and run into a trill, first a series of squeaks, "tsik-tsik", then loud "teew, teew", with whinnying "wipwipwip" at end; call a mournful "kou-lee, kou-lee" like a curlew (*Numenius*); also a squirrel-like scolding "tsik-tsik".

Habitat. Forest, upper canopy of old secondary evergreen forest and riverine forest, and forest edge, where active 8-30 m above ground, in tall dense thickets, tangled creepers and lianas; in thorn bush along Omo R in Ethiopia, in uncharacteristically arid habitat. Lowlands, not a bird of montane forests, though occurs to 2000 m in E Africa; in S Africa mainly in coastal scrub.

Food and Feeding. Insects, including caterpillars, beetles, grasshoppers, crickets, leaf-hoppers, bees, spiders; tree frogs, slugs, fruit, seeds, leaves. Moves by short hops, balances with its long tail, searches through tangled creepers, turning and seizing an insect; sometimes accompanies mixed-species flocks of birds or squirrels, using them as beaters to flush insects, which it then seizes. Occurs singly, in pairs or in small groups of 3-5.

Breeding. Laying dates Mar and May in Ghana, Oct-Dec and Feb in Sierra Leone, Jun and Aug in Nigeria, Jul in Uelle, Nov and Dec in S Africa. Nest an open mass of sticks, sometimes domed, usually unlined, 2-5 m above ground in dense vegetation. Eggs 2 (3), white to creamy, stained, sometimes chalky; 30 x 23 mm. Both parents feed young.

Movements. Resident, though observed seasonally Nov-Jun in forest islands in Gambia, and locally a nocturnal migrant along coast in Nigeria and Kenya.

Status and Conservation. Not globally threatened. Nowhere very common, but secretive behaviour of this forest and thicket cuckoo limits frequency of observations. Formerly common in charcoal forests of coastal Ghana; locally common near Oussouye in Parc National de Basse-Casamance in S Senegal; common in all kinds of forest in Sierra Leone. Population density in NE Gabon c. 15-20 pairs/km². Fairly common in South Africa.

Bibliography. Ash & Miskell (1983), Bannerman (1933, 1953), Bates (1930), Benson & Benson (1977), Benson *et al.* (1971), Britton (1980a), Brosset & Énard (1986), Brown & Britton (1980), Cave & Macdonald (1955), Chapin (1939), Cheke & Walsh (1996), Christy & Clarke (1994), Clancey (1964b), Colston & Curry-Lindahl (1986), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fry *et al.* (1988), Ginn *et al.* (1989), Giraudeau *et al.* (1988), Gore (1990), Grimes (1987), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Praed & Grant (1957, 1962, 1970), Maclean (1993), Nikolaus (1987), Pakenham (1979), Pérez de Val (1996), Pinto (1983), Rowan (1983), Short *et al.* (1990), Snow (1978), van Someren (1949), Thomas (1991), Wachter *et al.* (1997), Zimmerman (1972), Zimmerman *et al.* (1996).

Genus *PHAENICOPHAEUS* Stephens, 1815

52. Black-bellied Malkoha

Phaenicophaeus diardi

French: Malcoha de Diard **German:** Diardkuckuck **Spanish:** Malcoha Ventrinegro
Other common names: Lesser Green-billed/Black-billed Malkoha

Taxonomy. *Melias Diardi*, Lesson, 1830, Java; error = Sumatra.

Sometimes combined with *P. sumatranus*, *P. tristis* and *P. viridirostris* in a separate genus *Rhopodytes*. Two subspecies recognized.

Subspecies and Distribution.

P. d. diardi (Lesson, 1830) - S Myanmar (Tenasserim), S Thailand, Peninsular Malaysia and Sumatra.
P. d. borneensis (Salvadori, 1874) - Borneo.

Descriptive notes. 38 cm; 57 g. Adult long-tailed, grey above, wings blue-green; grey below, belly blackish grey, undertail tipped white; rugous red skin around eye, edge of eyelids black, iris bluish white, bill green with blue-grey base, feet dark grey. Juvenile similar, iris dark brown. Race *borneensis* smaller, more greenish (less grey) below. **Voice.** Sharp "pwew-pwew" call, also a soft "taup".

Habitat. Forests and second growth, swampy jungle, bamboo, typically occurring in dense undergrowth and creepers. Lowlands and foothills, to 1200 m.

Food and Feeding. Insects, including beetles,

ants, mantids, grasshoppers and caterpillars.

Breeding. Breeds Jan and Mar in Malaysia, Apr in Myanmar. Nest a shallow saucer of fine twigs, 18 cm in diameter, 3-4 cm deep, lined with green leaves, in a bush. Eggs 2-3, chalky white; 30 x 24-5 mm.

Movements. Resident.

Status and Conservation. Not globally threatened. Vulnerable to deforestation throughout its range, including Thailand, where species is still considered common. It appears to be rather uncommon in Malaysia, but perhaps more numerous in Sumatra. Although no breeding records are known for Borneo, it is resident and common there in lowlands.

Bibliography. Andrew (1992), Chasen (1939), Duckworth & Kelsh (1988), Ford & Davison (1995), Inskipp *et al.* (1996), Lekagul & Round (1991), MacKinnon & Phillips (1993), Madoc (1976), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986), Meyer de Schauensee & Ripley (1940), Nash & Nash (1985), Robinson *et al.* (1924), Round (1988), Schönwetter (1967), Smythies (1981, 1986), Thompson (1966), Wilkinson, Dutton & Sheldon (1991).

53. Chestnut-bellied Malkoha

Phaenicophaeus sumatranus

French: Malcoha à ventre roux **German:** Rotbauchkuckuck **Spanish:** Malcoha Ventrirrufo
Other common names: Rufous-bellied Malkoha

Taxonomy. *Cuculus Sumatranus* Raffles, 1822, hills of Sumatra.

Sometimes combined with *P. diardi*, *P. tristis* and *P. viridirostris* in a separate genus *Rhopodytes*. Bornean population sometimes separated subspecifically as smaller *minor*, but overlaps with birds elsewhere in range. Monotypic.

Distribution. S Myanmar (S Tenasserim), S Thailand and Peninsular Malaysia to Sumatra and Borneo and several of their satellite islands.

Descriptive notes. 40-41 cm; 114 g. Adult dark metallic green above, head grey, wings metallic greenish blue, tail bluish grey; throat and breast grey, belly and undertail-coverts rufous-chestnut, undertail tipped white; rough red skin around eye, iris blue-grey, bill green, feet leaden to grey-green. Juvenile similar, but rectrices narrower, white tips shorter and narrower. **Voice.** "Tok-tok" or "chi-chi", also a thin high-pitched mew.

Habitat. Forest edge, second growth, mangroves, durian plantations, in dense crowns of trees. Lowlands to 1200 m.

Food and Feeding. Locusts, mantids, stick

insects, leaf insects, crickets, grasshoppers, large hairy caterpillars and occasionally frogs. Quiet, creeps through saplings and thickets.

Breeding. Breeding records in Jul in Borneo; copulation witnessed in late Aug, Sumatra. Nest comprises a flat platform of sticks, lined with leaves, situated in low shrub to high in tree. Eggs 2, white; 27-5 x 24 mm.

Movements. Resident.

Status and Conservation. Not globally threatened. Reported to be very common in S Tenasserim, but uncommon in neighbouring parts of S Thailand and only fairly common in Malaysia; in Singapore, likely to be seen only in the Water Catchment Forest. In Sumatra and Borneo, species seems to remain relatively common. Vulnerable to further deforestation throughout its range, although it does adapt to second growth and plantations.

Bibliography. Andrew (1992), Chasen (1931, 1939), Coomans de Ruiter (1947), Duckworth & Kelsh (1988), Ford & Davison (1995), Gibson-Hill (1949), Hails & Jarvis (1987), Holmes (1996), Inskipp *et al.* (1996), Lekagul & Round (1991), MacKinnon & Phillips (1993), Madoc (1976), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986), Meyer de Schauensee (1940), Nash & Nash (1988), Round (1988), Smythies (1981, 1986), Wells (1990), Wilkinson, Dutton & Sheldon (1991).

54. Green-billed Malkoha

Phaenicophaeus tristis

French: Malcoha sombre **German:** Großer Grünschnabelkuckuck **Spanish:** Malcoha Sombrio
Other common names: Greater Green-billed/Large Green-billed Malkoha

Taxonomy. *Melias tristis* Lesson, 1830, Sumatra; error = Bengal.

Sometimes combined with *P. diardi*, *P. sumatranus* and *P. viridirostris* in a separate genus *Rhopodytes*. Six subspecies recognized.

Subspecies and Distribution.

P. t. tristis (Lesson, 1830) - N India from outer Himalayas (to 1800 m) and Kumaon S to Madhya Pradesh, E through Nepal, Sikkim and Bhutan to Assam and Bangladesh.
P. t. saliens (Mayr, 1938) - N Myanmar, N Thailand, N Indochina and S China (Yunnan).
P. t. hainanus (Hartert, 1910) - Hainan.
P. t. longicaudatus Blyth, 1842 - S Myanmar, S Thailand and S Indochina to Malaysia.
P. t. elongatus S. Müller, 1835 - Sumatra.
P. t. kangeangensis (Vorderman, 1893) - Kangean Is.

Descriptive notes. 50 cm; 115 g. Adult *tristis* dark grey with green gloss above, oily green wings and tail, tail very long with broad white tips; lower belly grey to blackish; bare red skin around eye, iris brown (or inner ring claret, outer ring white), bill pale green, feet greenish grey. Juvenile shorter-tailed. Race *saliens* shorter-winged, longer-tailed; *longicaudatus* long-winged, long-tailed; *hainanus* shorter-winged than *saliens*, shorter white tail spots; *elongatus* darker green-grey, long white tail spots; *kangeangensis* paler grey, long white tail spots. **VOICE.** A clucking and croaking frog-like call, "ko, ko, ko, ko", sometimes ending

with a run, "co-co-co-co"; cat-like chuckle when flushed.

Habitat. Primary forest, second growth, dense thickets, scrub, cultivated areas, rubber plantations, hill forest, bamboo. Lowlands to hills at c. 1600 m, locally to 1800 m; mostly below 700 m in Nepal.

Food and Feeding. Insects, large caterpillars, Orthoptera, also lizards. Feeds in dense foliage in thickets and trees.

Breeding. Breeds Apr-Aug in India, May in Nepal, Mar-Sept in Myanmar, Jan-Mar in Peninsular Malaysia; young bird being fed by parents in early May, Sumatra. Nest a small platform of twigs, lined with green leaves, in middle of small tree (in Thailand, closed nest high in tree reported seen with naked eye only). Eggs 3 (2-4) in India, 2-3 in Myanmar, 2 in Thailand and Peninsular Malaysia, chalky white; 34 x 26 mm. Both sexes incubate.

Movements. Resident.

Status and Conservation. Not globally threatened. Common or very common resident throughout much of its expansive range. Said to be fairly common in Nepal up to 700 m, but uncommon at higher elevations; rare in Hainan. Adaptability to a number of man-modified habitats suggest species is probably not immediately at risk.

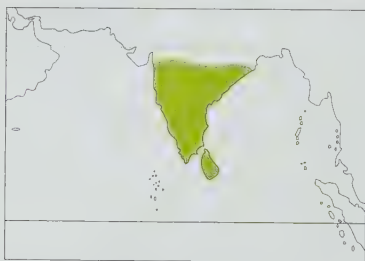

Bibliography. Abdulali (1971), Ali (1996), Ali & Ripley (1981), Ali *et al.* (1996), Biswas (1960), Chasen (1939), Deignan (1945), Échécopar & Hüe (1978), Harvey (1990), Holmes (1996), Inskipp & Inskipp (1991), Junge & Kooiman (1951), Lekagul & Round (1991), MacKinnon & Philipps (1993), Madoc (1976), Majumdar *et al.* (1992), van Marle & Voous (1988), Medway & Wells (1976), Ripley (1982), Robinson & Kloss (1931), Smythies (1986), Stepanyan (1995), Thewlis *et al.* (1996), Yang Lan *et al.* (1995).

55. Blue-faced Malkoha*Phaenicophaeus viridirostris*

French: Malcoha à bec vert **German:** Kleiner Grünschnabelkuckuck **Spanish:** Malcoha Cariatul
Other common names: Lesser Green-billed/Small Green-billed Malkoha

Taxonomy. *Zanclostomus viridirostris* Jerdon, 1840, bottom of the Coonoor Pass, India. Sometimes combined with *P. diardi*, *P. sumatranus* and *P. tristis* in a separate genus *Rhopodytes*. Monotypic.

Distribution. Peninsular India from about NW Maharashtra and C Orissa S to Sri Lanka.

Descriptive notes. 39 cm; 77 g. Adult greenish grey above, head slate-grey, wings glossy blue-green, tail long, graduated, black with white tips; throat and breast dark grey with light grey hackles forked at tip (appear wet), belly grey and buff, undertail-coverts dark grey; colourful bare pale blue skin around eye, iris with narrow white outer ring, dark red inner ring, bill pale green, feet slaty-blue. Juvenile less green-glossed above, paler below; outer primary softer and broader than in adult (where sickle-shaped), tail feathers narrower, central pair with narrow pale tip. Flight slow, direct, laboured, on short, rounded wings.

VOICE. Call a low croak, "kraa".

Habitat. Secondary woodland, thorn scrub and bush, especially with *Euphorbia antiquorum*. Low country to hills at 1000 m.

Food and Feeding. Insects, caterpillars, grasshoppers, mantids, cicadas, beetles; also lizards, fruit. Spends time in branches and thickets, peering at leaves for insects; usually singly or in pairs.

Breeding. Breeds nearly all year, mainly Mar-May in S India. Nest a bulky saucer of twigs lined with green leaves, near ground to 1-2 m above. Eggs 2 (3), chalky white; 29 x 25 mm. Hatchling with blackish skin, white hair-like down.

Movements. Resident.

Status and Conservation. Not globally threatened. Widespread though not abundant throughout most of its range, in a habitat that is not immediately at risk; common in dry zone of low country in Sri Lanka, e.g. in Uda Walawe, Bundala and Yala National Parks.

Bibliography. Abdulali (1971), Ali (1996), Ali & Ripley (1981), Ali & Whistler (1937), Chakravarthy & Purna Chandra Tejasvi (1992), Henry (1971), Inskipp *et al.* (1996), Kotagama & Fernando (1994), Legge (1880), Philipps (1978), Ripley (1982), Saha & Dasgupta (1992), Wait (1925), Wheatley (1996), Wijesinghe (1994).

56. Sirkeer Malkoha*Phaenicophaeus leschenaultii*

French: Malcoha sirkir **German:** Sirkarkuckuck **Spanish:** Malcoha Sirkir
Other common names: Sirkeer (Cuckoo), Southern Sirkeer

Taxonomy. *Taccocua leschenaultii* Lesson, 1830, Madras.

Sometimes retained in the monotypic genus *Taccocua*, in which it was originally named. Three subspecies recognized.

Subspecies and Distribution.

P. l. sirkee (J. E. Gray, 1831) - Pakistan (Sind, Punjab) and NW India.
P. l. infuscata (Blyth, 1845) - India in sub-Himalayan *terai* and *duars* from Kumaon through Nepal to W Assam and Bangladesh, and S to SC Maharashtra and N Andhra Pradesh.
P. l. leschenaultii (Lesson, 1830) - S India and Sri Lanka.

Descriptive notes. 43 cm; 174 g. Adult sandy-rufous above with black shaft streaks to head and breast, long tail blackish brown with broad white tips on outer feathers, inner rectrices unmarked sandy-rufous; throat and breast light brown, belly sandy-rufous; feathered around eye with narrow blue orbital skin, iris red to brown, bill red with yellow tip, feet dark grey. Juvenile, above feathers edged pale rufous, below streaked with black. Race *infuscata* paler, *sirkee* palest. **VOICE.** Silent; occasional shriek, "kek-kek-kek-kerek-kerek".

Habitat. Dry deciduous secondary forest, scrub and bush, with undergrowth of lantana

and thick grass, thorn and grass jungle, dry stony hillsides. Plains and foothills to 1000 m, in Nepal mainly to c. 360 m.

Food and Feeding. Large insects, grasshoppers, mantids, caterpillars, termites, also lizards, berries, fruits. Terrestrial, feeds mainly on ground, often runs; occasionally flies from one tree to another.

Breeding. Breeds mainly Jun-Sept in India, Jun-Jul in Sri Lanka. Nest a saucer of twigs lined with green leaves, near ground. Eggs 2-3, chalky white; 36 x 26 mm. Both sexes incubate.

Movements. Resident.

Status and Conservation. Not globally threatened. Generally a rather rare species; uncommon in S India. Its range extends from lowlands to foothills, to the level where tea and rubber plantations have replaced the previous vegetation of scrub and forest. In first half of 20th century, it expanded its range into drier areas of Sind, Pakistan, along irrigation canals. Uncommon and local in dry zone of low country in Sri Lanka, but frequent in parts of Uda Walawe National Park.

Bibliography. Ali (1996), Ali & Ripley (1981), Ali & Whistler (1937), Biswas (1960), Harvey (1990), Henry (1971), Inskipp, C. (1989), Inskipp, C. & Inskipp (1991), Inskipp, T. *et al.* (1996), Kotagama & Fernando (1994), Legge (1880), Mahabal & Lamba (1987), Majumdar *et al.* (1992), Mukherjee (1995), Philipps (1978), Ripley (1982), Roberts (1991), Wheatley (1996), Wijesinghe (1994), Zacharias & Gaston (1993).

57. Raffles's Malkoha*Phaenicophaeus chlorophaeus*

French: Malcoha de Raffles **German:** Bubukuckuck **Spanish:** Malcoha de Raffles

Taxonomy. *Cuculus chlorophaeus* Raffles, 1822, forests of Sumatra.

Sometimes placed in a monotypic genus *Rhinorhina*, the only malkoha to show marked sexual dimorphism. Two subspecies recognized.

Subspecies and Distribution.

P. c. chlorophaeus (Raffles, 1822) - S Myanmar (Tenasserim), S Thailand and Peninsular Malaysia to Sumatra and N, E & S Borneo.

P. c. fuscicularis (Stuart Baker, 1919) - NW Borneo (Sarawak, NW Kalimantan).

Descriptive notes. 32 cm; 52.5 g. Adult male rufous above, head rufous, tail black, finely barred grey and broadly tipped white; rufous throat and breast, dark grey belly, grey vent; bare skin around eye light blue-green, iris dark brown, bill light green, feet green-grey. Female with head and mantle light grey, back, wings and tail rufous, tail with subterminal black band and white tip, grey underparts, chestnut vent, iris yellow to dark brown. Juvenile resembles adult. Race *fuscicularis* smaller, female washed buffish. **VOICE.** A soft mournful "miaow", 3-6 notes on descending scale; also harsh croaks and a chirp.

Habitat. Primary forest, also second growth, forest edge, heath scrub, overgrown plantations, locally gardens. Lowlands to 900 m.

Food and Feeding. Mostly insects, mainly caterpillars, also butterflies, cicadas, crickets, beetles, locusts. Creeps through dense vegetation, searches for caterpillars on leaves of trees; feeds in middle storey, among creepers on tree trunks, peers under leaves for large insects; moves about looking like a squirrel.

Breeding. Breeds Jan and May in Peninsular Malaysia; oviduct egg Jan in Borneo. Nest undescribed. Eggs 2-3, white; 33 x 25 mm.

Movements. Resident.

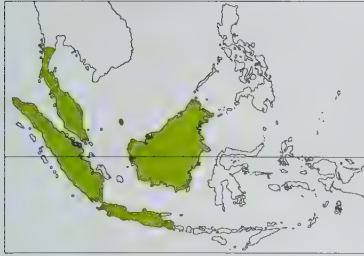

Status and Conservation. Not globally threatened. A common species throughout most of its sizeable range. Frequent observation in degraded, secondary and man-modified habitats suggests species may be relatively adaptable in face of the major habitat destruction affecting vast portions of its range.

Bibliography. Andrew (1992), Chasen (1939), Ford & Davison (1995), Gibson-Hill (1949), Inskipp *et al.* (1996), Lekagul & Round (1991), MacKinnon & Philipps (1993), Madoc (1976), van Marle & Voous (1988), Mayr (1938), Medway & Wells (1976), Mees (1986), Meyer de Schauensee & Ripley (1940), Nash, A.D. & Nash (1985), Nash, S.V. & Nash (1988), Ripley (1942), Robinson *et al.* (1924), Schönwetter (1967), Smythies (1981, 1986), Wilkinson, Dutson & Sheldon (1991).

58. Red-billed Malkoha*Phaenicophaeus javanicus*

French: Malcoha javanais **German:** Kastanienbauchkuckuck **Spanish:** Malcoha Piquirrojo

Taxonomy. *Phaenicophaeus* [sic] *Javanicus* Horsfield, 1821, Java. Sometimes placed in monospecific genus *Zanclostomus*. Monotypic.

1000 m, occasionally to 1500 m.

Distribution. S Myanmar (Tenasserim) and S Thailand through Peninsular Malaysia to Sumatra, Natuna Is, Borneo and Java.

Descriptive notes. 42 cm; 98 g. Adult grey above, glossed bluish green on back and wings, tail tipped white; rufous below with grey lower-breast bar; bare skin around eye grey or blue, iris brown, bill red with blackish culmen, legs slaty. Juvenile similar, but rectrices narrow, white tip of tail shorter (central feathers: 8 mm in juvenile, 18 mm in adult). **VOICE.** A striking whining call, a quiet and deep "kuk".

Habitat. High trees in drier forest, forest edge, secondary scrub. Lowlands and hilly areas to

Food and Feeding. Large insects, cicadas, stick insects (phasmids), grasshoppers (Acrididae, Tettigoniidae), mantids, beetles (Scarabaeidae), bugs, winged termites, caterpillars (Sphingidae), pupae (Pieridae); also spiders and crustaceans.

Breeding. Breeds Jun in Peninsular Malaysia, Apr in Kalimantan. Monogamous, lives in pairs. Nest a flimsy platform of twigs. Eggs chalky white; 29 x 23 mm.

Movements. Resident.

Status and Conservation. Not globally threatened. The least common malkoha species in Borneo, where it has, however, shown itself capable of adapting to cocoa plantations; also rather infrequent in Sumatra and Java. Rare in Myanmar and uncommon in Peninsular Malaysia, but reported to be common in intervening area in Thailand.

Bibliography. Andrew (1992), Chasen (1939), Duckworth & Kelsh (1988), Ford & Davison (1995), Gibson-Hill (1949), Hellebrekers & Hoogerwerf (1967), Holmes (1996), Holmes & Burton (1987), Inskipp *et al.* (1996), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Phillipps (1993), van Marle & Voous (1988), Medway & Wells (1976), Nash & Nash (1988), Schönwetter (1967), Smythies (1981, 1986), Sody (1989), Thompson (1966), Wilkinson, Dutson & Sheldon (1991).

59. Yellow-billed Malkoha

Phaenicophaeus calyrorhynchus

French: Malcoha à bec peint **German:** Buntschnabelkuckuck **Spanish:** Malcoha de Célebes
Other common names: Fiery-billed/Celebes Malkoha

Taxonomy. *Phaenicophaeus calyrorhynchus* Temminck, 1825, Sulawesi.
Forms a superspecies with *P. curvirostris*, the two sometimes placed in a separate genus *Rhamphococcyx*. Three subspecies recognized.
Subspecies and Distribution.
P. c. calyrorhynchus Temminck, 1825 - N, E & SE Sulawesi and Togian Is.
P. c. meridionalis (A. B. Meyer & Wigglesworth, 1896) - C & S Sulawesi.
P. c. rufiloris Hartert, 1903 - Butung.

Descriptive notes. 53 cm. Adult back rufous-maroon above, crown and face dark grey, wings dark purple, tail black; throat and breast rufous, belly dark grey; iris red; bill deep, curved, yellow above, tip black with white spot, below nostril and lower mandible red. Juvenile resembles adult, but iris brown, bill yellow. Race *calyrorhynchus* darker; *meridionalis* paler on crown and below; *rufiloris* has feathering above lores dark rufous, rather than grey. **VOICE.** Call a short winding-up rattle.
Habitat. Inhabits secondary forest and forest edge, also coconut plantations, riverine vegetation near villages. Occurs from sea-level up

to 1300 m.
Food and Feeding. Insects, including hairy caterpillars, locusts and mantids, and beetles. Hops and creeps around the canopy like a squirrel; follows macaque monkey groups and catches insects flushed by the monkeys; also follows *Centropus celebensis*.
Breeding. Breeds Nov-Dec. Nest undescribed. Eggs white; 36 x 31 mm; clutch size not recorded. Although apparently a nesting species, a juvenile was fed by a Crimson Sunbird (*Aethopyga siparaja*) in Sulawesi.
Movements. Resident.
Status and Conservation. Not globally threatened. Very little known about status, but occurrence at forest edge, in coconut groves and relatively near human habitation may suggest certain adaptability; biology also poorly known, research required. Common in suitable habitat in Dumoga-Bone National Park in mid-1980's.
Bibliography. Andrew (1992), Coates & Bishop (1997), Fooden (1969), Fraser & Henson (1996), Holmes & Phillips (1996), Inskipp *et al.* (1996), Jepson (1997), Rozendaal & Dekker (1989), Schönwetter (1967), Stresemann (1940), Watling (1983), Wheatley (1996), White & Bruce (1986), Whitten, Mustafa & Henderson (1987).

60. Chestnut-breasted Malkoha

Phaenicophaeus curvirostris

French: Malcoha rouverdin **German:** Schimmerkuckuck **Spanish:** Malcoha Pechicastaño
Other common names: Palawan Malkoha (*harringtoni*)

Taxonomy. *Cuculus curvirostris* Shaw, 1810, western Java.
Forms a superspecies with *P. calyrorhynchus*, the two sometimes placed in a separate genus *Rhamphococcyx*. Populations of Sumatra have on occasion been listed as race *erythrognathus*. Six subspecies recognized.
Subspecies and Distribution.
P. c. singularis (Parrot, 1907) - S Myanmar (Tenasserim) and S Thailand through Peninsular Malaysia to Sumatra.
P. c. oeneicaudus J. & E. Verreaux, 1855 - Mentawai Is (off W Sumatra).
P. c. curvirostris (Shaw, 1810) - W & C Java.
P. c. deningeri Stresemann, 1913 - E Java and Bali.
P. c. microrhinus Berlepsch, 1895 - Borneo and Bangka.
P. c. harringtoni (Sharpe, 1877) - SW Philippines (Balabac, Palawan, Calamianes).

Descriptive notes. 42-49 cm; 122 g. Adult dark glossy green above (blue in worn plumage), head grey, narrow white supercilium, tail broadly tipped vinaceous (no white); dark vinaceous below; rough bare skin around eye red, iris white to yellow to red; bill curved, light green to yellow to horn above, red to black below, feet dark grey. Juvenile more feathered on face, tail feathers narrower, bill yellow with mostly black lower mandible. Race *curvirostris* as above, nostril oval with long anterior groove in adult; *deningeri* paler, lower face light grey, throat light rufous; *singularis* has cheeks and chin grey, belly black, bill green with red below nostril and on lower mandible; *microrhinus* with head dark grey (chin rufous on some), dark reddish brown below, bill green with red below nostril and on lower mandible, nostril ungrooved; *oeneicaudus* generally darker with greenish flanks, central rectrices all green (outer rectrices with rufous tip); *harringtoni* often paler below, with head grey washed olive brown, narrow grey strip below eye, bill yellow to green with red below, nostril vertical, ungrooved. **VOICE.** A low "kuk-kuk", ticking or knocking calls like a clucking chicken, and a fast "kok-kok-kok" in flight.
Habitat. Thickets in primary forest, forest edge, second growth, creepers, vines, plantations, gardens, mangroves. On both mainland and islands from lowlands up to 1100 m.

Food and Feeding. Insects, including caterpillars (hairy and hairless) (Lasiocampidae), grasshoppers (Acrididae), crickets, beetles, cockroaches, stick insects, locusts; also small crabs, nestling birds, lizards, frogs, rats. Perches motionless in tree canopy, for several minutes, watching for prey; also moves around, hops and swings tail like a squirrel.

Breeding. Breeds Jan-Mar in Malaysia (eggs), Jan in Sumatra (eggs), Apr, Jul and Nov in Java (nestlings, recently fledged young). Nest a thick platform of dead twigs, lined with leaves, in fork of tree. Eggs 2-3, chalky white, stained by dirt; 39 x 28 mm.
Movements. Resident.
Status and Conservation. Not globally threatened. A common species in lowlands of S Thailand, Borneo and Philippines, and fairly common to common in Peninsular Malaysia, Sumatra, Java and Bali; in NW of range, locally even very common, in S Myanmar. Extensive use of secondary and marginal habitats suggests species relatively secure.
Bibliography. Andrew (1992), Büttikofer (1901), Chasen (1939), Deignan (1952), Dickinson *et al.* (1991), Duckworth & Kelsh (1988), Ford & Davison (1995), Hellebrekers & Hoogerwerf (1967), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Phillips (1993), Madoc (1976), van Marie & Voous (1988), Medway & Wells (1976), Mees (1986, 1996), Robinson *et al.* (1924), Smythies (1981, 1986), Sody (1989), Stresemann (1913a), Thompson (1966), Wilkinson, Dutton & Sheldon (1991).

61. Red-faced Malkoha

Phaenicophaeus pyrrhocephalus

French: Malcoha à face rouge **German:** Nackstirnckuckuck **Spanish:** Malcoha Carirrojo

Taxonomy. *Cuculus pyrrhocephalus* Pennant, 1769, Sri Lanka.
Monotypic.

Distribution. Sri Lanka.

Descriptive notes. 45-47 cm. Adult black above, glossed green and blue, crown and neck finely streaked white, tail black with broad white tips; chin and lower face whitish, throat and breast black, belly white; very prominent bare rugous red skin on face, iris brown in male, white in female; bill stout, curved, light yellowish green; feet slaty grey. Juvenile shorter-tailed, smaller red face patch, breast with white streaks. **VOICE.** Mostly silent; sometimes short single yelping whistles, also a "kok", and a low whining "kra".
Habitat. Dense forest in wet zone, also riverine forest in dry zone of N & E Sri Lanka, disap-

pearing in cultivated areas. Lowlands to 1700 m.
Food and Feeding. Fruits and berries of forest trees. Hops from branch to branch, flutters and sails from tree to tree. Usually forages in mixed feeding flocks, characteristically led by Orange-billed Babblers (*Turdoides rufescens*) and containing mostly medium-sized birds; normally 2-4 malkohas in a flock, although up to 6 have been recorded.
Breeding. Breeds Jan-May; also gonads enlarged to Aug-Sept. Nest a shallow saucer near ground, in dense undergrowth. Eggs 2-3, chalky white; 36 x 27 mm.
Movements. Resident.
Status and Conservation. **VULNERABLE.** Although not uncommon locally, this species is generally scarce and is mostly restricted to fragmented small local populations in wet zone of SW Sri Lanka. Its numbers have declined through shooting and through loss of habitat to cultivation. All specimen records are from Sri Lanka; several old, unconfirmed sight records have come from S India, in S Kerala and W Tamil Nadu, but these are now considered more likely to be misidentifications.
Bibliography. Ali & Ripley (1981), Biddulph (1956), Collar & Andrew (1988), Collar *et al.* (1994), Henry (1971), Hoffmann (1984, 1989a), Inskipp *et al.* (1996), Kotagama & Fernando (1994), Legge (1880), Phillips (1978), Ripley (1982), Tirimanna (1981), Wheatley (1996), Wijesinghe (1994).

62. Rough-crested Malkoha

Phaenicophaeus superciliosus

French: Malcoha à sourcils rouges **German:** Rotbrauenkuckuck **Spanish:** Malcoha Crestirrojo
Other common names: Red-crested Cuckoo

Taxonomy. *Phaenicophaeus* [sic] *superciliosus* Dumont, 1823, Philippines.
Sometimes placed in monotypic genus *Dasylophus*. Two subspecies recognized.

Subspecies and Distribution.
P. s. cagayanensis Rand & Rabor, 1967 - Cagayan Province, NE Luzon.
P. s. superciliosus Dumont, 1823 - Luzon (W & S of range of previous race).

Descriptive notes. 38 cm; male 115 g, female 120 g. Adult all glossy black, short red eye-brow crest, white tips to tail, bare skin around eye red to yellowish orange, iris yellow, bill pale green with orange base, legs and feet greenish at front, yellow behind. Juvenile all black or with brown forehead, no red crest at fledging (crest develops shortly afterwards, replaces brown forehead), shorter white tips to tail, bill brown to green. Race *cagayanensis* has crest shorter, the components of both sides meeting and merging on forehead, breast paler. **VOICE.** Short, ascending metallic whistles.
Habitat. Forests, also grassland with bushes;

recorded at altitudes of 100-800 m.
Food and Feeding. Large insects (katydids, beetles), also worms, lizards. Creeps and hops in tangles of vines, drops to ground to grab insects that fall from branches as it disturbs them.
Breeding. Breeds May-Jun. Nest undescribed. Young fledge by time they reach 60 g.
Movements. Resident.
Status and Conservation. Not globally threatened. Appears to be fairly common in forests, but these are being heavily depleted throughout the species' range. Present in degraded forest of Angat Watershed, N of Manila, where forest remains because it protects the catchment area of this impor-

tant water supply for Manila; also present in Quezon National Park, C Luzon, but habitat under immediate threat at this site, where deforestation is going on despite protected status. Populations should be monitored, in order to establish current status of species.

Bibliography. Danielsen *et al.* (1994), Delacour & Mayr (1946), Dickinson *et al.* (1991), DuPont (1971), Gonzales (1983), Goodman & Gonzales (1990), Inskipp *et al.* (1996), McGregor (1909-1910), Ogilvie-Grant (1895), Poulsen (1995).

63. Scale-feathered Malkoha

Phaenicophaeus cumingi

French: Malcoha fris  **German:** Schuppenhalskuckuck **Spanish:** Malcoha Frisado
Other common names: Scale-feathered/Scaly Cuckoo

Taxonomy. *Phoenicophaeus* [sic] *Cumingi* Fraser, 1839, Luzon. Sometimes placed in monotypic genus *Lepidogrammus*. Monotypic.
Distribution. Luzon, Marinduque and Catanduanes (N Philippines).

Descriptive notes. 42 cm; male 177 g, female 170 g. Adult dark brown above, head grey, forehead and throat whitish (head and throat with flat, scaly glossy blue-black feathers), wings and rump glossy dark green to blue, tail blacker with white tip; breast chestnut, belly dull black; bare skin around eye red, iris red, bill pale creamy-buff to brown, feet grey. Juvenile with most of head, wings and body dark reddish brown, neck rufous; scaly head feathers grow while bird still short-tailed. Voice. Metallic and higher-pitched compared with voice of *P. superciliosus*.

Habitat. Forest. Lowlands to 2000 m.

Food and Feeding. Insects, centipedes, worms, and small lizards. Forages mainly in lower layers of forest, climbs to 12 m in vines.

Breeding. Little information. Presumably breeds Mar-May (estimated from juveniles). Nest undescribed.

Movements. Resident.

Status and Conservation. Not globally threatened. Seems to be fairly common, but the continued destruction of its forest habitat must surely present a major threat; apparently somewhat less frequent than *P. superciliosus*. Present in degraded forest of Angat Watershed, N of Manila, where forest remains because it protects the catchment area of this important water supply for Manila; also present in Quezon National Park, C Luzon, but habitat under immediate threat at this site, where deforestation is going on despite protected status. Populations require monitoring.

Bibliography. Alonzo-Pasicolan (1992), Danielsen *et al.* (1994), Delacour & Mayr (1946), Dickinson *et al.* (1991), DuPont (1971), Gilliard (1950b), Gonzales (1983), Gonzales & Rees (1988), Goodman & Gonzales (1990), Hachisuka (1934), Inskipp *et al.* (1996), Manuel (1937), McGregor (1909-1910).

Genus CARPOCOCYX G. R. Gray, 1840

64. Sumatran Ground-cuckoo

Carpococcyx viridis

French: Calobate de Sumatra **German:** Sumatrakuckuck **Spanish:** Cuco Terrestre de Sumatra
Other common names: Sunda/Green-billed/Malay Ground-cuckoo (with *C. radiatus*)

Taxonomy. *Carpococcyx viridis* Salvadori, 1879, Mount Singgalang, Sumatra. Usually treated as conspecific with *C. radiatus*, but clearly smaller and shows distinct plumage differences from latter at all ages. Monotypic.

Distribution. SW Sumatra (foothills of Barisan Range).

Descriptive notes. 55 cm. Adult black on crown, shading to green on hindcrown; mantle, upper back, neck sides, wing-coverts and secondaries dull green, lower back brown with broad greenish brown bars, wings and tail glossy greenish black; lower throat and upper breast dull greyish green, rest of underparts cinnamon-buff, more rufous on flanks, finely barred brownish green on lower breast and brown on belly and flanks; bare skin above eye green, behind eye lilac and on cheek blue, iris dull reddish, bill green, paler below, tarsi green. Lacks dark-hooded appearance and purplish or coppery hues on upperparts of *C.*

radiatus. Juvenile rufous-chestnut above with indistinct brown barring, wings and tail variable greenish rufous, chin to breast mottled brownish, shading to rufous-buff on belly, belly and vent faintly barred, smaller area of bare skin around eye than in adult, iris dark grey, bill horn-black, feet dark grey. Voice. Unknown.

Habitat. Forest in hilly areas, where lives on the ground. Between 300 and 1400 m.

Food and Feeding. Insects.

Breeding. Unknown.

Movements. Resident.

Status and Conservation. **VULNERABLE.** True status of species has until recently been concealed by the fact that it was treated as conspecific with Bornean *C. radiatus*. Present species is in fact seriously in danger, and might even be extinct. Known only from 8 museum specimens, all from areas in which the Sumatran rhinoceros (*Dicerorhinus sumatrensis*) was also known. It has not been observed in the wild since 1916, but ground-cuckoos are unobtrusive and it may possibly still persist in some forest areas. At least a third of the montane forest and most lowland forest on Sumatra has been lost, however, and the continuing headlong destruction of this habitat is likely to

be the most serious threat to the survival of this species. Field research is required to determine the location and extent of any remaining populations.

Bibliography. Andrew (1992), Arbocco *et al.* (1978), Collar & Andrew (1988), Collar & Long (1996), Collar *et al.* (1994), Finsch (1898), Holmes (1996), Inskipp *et al.* (1996), Jepson (1997), MacKinnon & Philipps (1993), van Marle & Voous (1988), Robinson & Kloss (1918, 1923), Robinson *et al.* (1924), Wheatley (1996).

65. Bornean Ground-cuckoo

Carpococcyx radiatus

French: Calobate de Borneo **German:** Laufkuckuck **Spanish:** Cuco Terrestre de Borneo
Other common names: Sunda/Green-billed/Malay Ground-cuckoo (with *C. radiatus*), Radiated Fruit-cuckoo

Taxonomy. *Calobates radiatus* Temminck, 1832, Pontianak district, western Borneo. Usually treated as conspecific with *C. viridis*, but clearly larger and shows distinct plumage differences from latter at all ages. Often referred to as *C. radiceus*, but this name resulted from an error in the original description, subsequently (1838) emended by Temminck himself to *C. radiatus*. Monotypic.

Distribution. Borneo.

Descriptive notes. 60 cm. Adult with head purple-glossed black, neck sides grey, mantle and back dull green with purple gloss with coppery-red reflections, lower back and rump rufous with faint dark bars, wings and tail unbarred coppery-violet; chin and throat black, rest of underparts barred white and black; bare skin around eye green, iris brown or grey, bill green, tarsi green. Juvenile like adult, but crown greenish brown, and unbarred uniform pale rufous below, some with grey throat. Voice. A cough, "heh heh heh"; loud 2-note call, "tock-tor", first note rising and second falling, dove-like or barbet-like in quality; also

loud 2-note "koohoo" like that of *Eudynamis scolopacea*.

Habitat. Forest, particularly lowland and hill forest in Brunei, primary forest on limestone soils in Sabah. Terrestrial, but nests and roosts in trees. At 300-1700 m.

Food and Feeding. Mainly insects, including beetles and giant ants; also takes fruit. Lives on the ground, where runs and jumps; sometimes follows army-ant swarms.

Breeding. Nest undescribed, in trees. Eggs white, 47 x 35 mm.

Movements. Resident.

Status and Conservation. **VULNERABLE.** Rare and patchy in distribution, though it is widespread throughout Borneo, albeit with very few recent records. Vulnerable to continuing degradation and loss of forest through human activity. Research required.

Bibliography. Andrew (1992), Beddard (1901), B tikofer (1901), Collar & Andrew (1988), Collar & Long (1996), Collar *et al.* (1994), Davison (1979), Finsch (1898, 1901), Holmes & Burton (1987), Inskipp *et al.* (1996), Jepson (1997), MacKinnon & Philipps (1993), Mayr (1938), Robinson *et al.* (1924), Sch n wetter (1967), Smythies (1981), Wheatley (1996).

66. Coral-billed Ground-cuckoo

Carpococcyx renauldi

French: Calobate de l'Annam **German:** Renauldckuckuck **Spanish:** Cuco Terrestre de Indochina
Other common names: Renauld's Ground-cuckoo

Taxonomy. *Carpococcyx Renauldi* Oustalet, 1896, Province of Quang-tri, Annam. Monotypic.

Distribution. Thailand, Laos, Cambodia and Vietnam (absent from Tonkin).

Descriptive notes. 65 cm; 400 g (captive, 44 days after hatching, when nearly grown). Adult grey above, head, neck and throat black, rump unbarred dark grey to rufous, primaries and tail black, tail glossed violet; white below, lower breast and grey belly finely vermiculated blackish; bare skin around eye red and violet, iris dull orange to yellowish, bill dusky red, rectal area violaceous blue, feet red. Juvenile dark grey above, head brown with grey around eye, back barred rufous, rump brown, wing-coverts barred rufous, chin to upper breast grey to rufous-brown, iris light brown, bill and feet blackish brown. Voice. Low melancholy whistle, rolling whistle; also duet, with one bird giving 3-note "whup, whoo-up", the other a rolling gargle; male gives bill-clack as last sound of "coo-cuh-clack".

Habitat. Forests (lower and middle strata), second growth, scrub, dense cover on ground, rocky areas. Terrestrial, but nests and roosts in trees. Lowlands to 900 m.

Food and Feeding. Insects, small reptiles, small mammals, small birds; captives require a high-protein diet, maintained on pigeon grain, take newborn mice, adult mice, crickets, mealworms and earthworms. In natural habitat a shy ground-living species, runs from disturbances, but quick and agile, capable of strong rapid flight when disturbed from cover.

Breeding. Nest an open platform of leaves and branches, twigs of figs, lined with leaves, 36 cm wide and 8 cm deep, built by both sexes, in tree; in captivity, use an open basket placed 2m above ground. Eggs 2-4, laying interval 2-3 days, white; 44 x 34 mm; incubation by both sexes (in captivity) c. 28 days (18-19 days in incubator at 37-6 C and 60-70% humidity). Nestling skin brown, brownish black down on wings and body, feather sheaths dark grey, palate red with white markings, palate colours faded by independence; fed by both parents, fledging 18 days, feeds self from 28 days; independent at 50-60 days, when may be driven off by adult male when the parents nest again.

Movements. Resident.

Status and Conservation. Not globally threatened. Currently considered near-threatened. Uncommon in Thailand, where still fairly numerous in semi-evergreen forests in parts of NE & SE up to 800 m, in selectively logged forest. Caught in noose traps for food and for the cagebird trade.

Uncommon in Vietnam, where forests have been subject to heavy logging. Has bred and raised its young successfully in captivity in planted aviaries, although wild-caught birds are shy in captivity, and captive-raised young do not breed before 3 years of age.

Bibliography. Atkinson (1982), Collar *et al.* (1994), Delacour & Jabouille (1931), Eames (1996), Hughes (1997a), Inskipp *et al.* (1996), Lekagul & Round (1991), Robiller *et al.* (1992), Robson (1990c), Robson *et al.* (1993a), Round (1988), Schönwetter (1967), Stepanyan (1995), Walters (1996), Wheatley (1996), Wylie & Shelton (1982).

PLATE 65

inches 6
 cm 15

Tribe COUINI

Genus *COUA* Schinz, 1821

67. Snail-eating Coua

Coua delalandei

French: Coua de Delalande **German:** Delalande-Seidenkuckuck **Spanish:** Cúa de Delalande
Other common names: Delalande's Coua

Taxonomy. *Coccyzus* [sic] *Delalandei* Temminck, 1827, Madagascar. Monotypic.
Distribution. NE Madagascar, where only definitely known from Nosy Boraha (Île Sainte-Marie). Almost certainly extinct.

Descriptive notes. 56–57 cm. Large terrestrial coua. Adult black above with violet-blue sheen, long violet-blue tail tipped white; throat to breast white, belly rufous; bare skin of face blue, iris red, bill black, feet black. Juvenile unknown. **VOICE.** Unknown.
Habitat. Apparently restricted to primary rain forest, near sea-level.
Food and Feeding. Large forest snails. Obtained food by breaking snail shells against a stone anvil with its bill.
Breeding. Unknown.
Movements. Unknown. Presumably resident and sedentary.

Status and Conservation. Almost certainly EXTINCT. Last reported on Nosy Boraha in 1834, with all 14 known museum specimens being taken no later than 1850. There is no certain evidence that it occurred on the mainland of Madagascar at any time. The species disappeared with deforestation. Secondary causes of loss include snaring and hunting for its feathers and meat, its stone anvils perhaps becoming the focus for hunters and ultimately monuments to the coua's extinction; possibly also affected by the introduction of rats, which may have reduced the mollusc diversity and numbers.
Bibliography. Ackerman (1841), Appert (1980), Benson & Schüz (1971), Benson *et al.* (1976–1977), Berlioz (1948), Collar & Andrew (1988), Collar & Stuart (1985), Collar *et al.* (1994), Dee (1986), Delacour (1932a), Dowsett & Forbes-Watson (1993), Fisher (1981), Fuller (1987), Goodman (1993), Greenway, J.C. (1967), Keith *et al.* (1974), Langrand (1990), Lavauden (1932), Milne-Edwards & Grandidier (1879), Milon (1952), Milon *et al.* (1973), Morgan (1975), Petter (1963), Rand (1936), Schifter (1973), Schuurman (1996), Sganzin (1840), Voisin & Voisin (1991).

68. Giant Coua

Coua gigas

French: Coua géant **German:** Riesen-Seidenkuckuck **Spanish:** Cúa Gigante
Other common names: Giant Madagascar Coucal

Taxonomy. *Cuculus gigas* Boddaert, 1783, Madagascar. Monotypic.
Distribution. S & W Madagascar, in coastal lowlands N to Betsiboka R.

Descriptive notes. 58–62 cm; 415 g. Adult dull olive-grey above, face black, tail glossy blackish with white tips; throat and upper breast creamy white, lower breast tan, belly rufous to black; bare skin around eye blue, pink behind eye, iris brown to red-brown, bill black, feet black. Juvenile duller, bill pale, fawn spots on wing and scapulars. **VOICE.** Calls from ground or in low tree, a deep “wok wok wok...” and guttural “ayoo-ew”, also a resonant “koo-kookookoogogo” with last 2 syllables lower; also short grunts.
Habitat. Deciduous forest, thorn scrub in areas of calcium-rich soil, forest and brush on sand, gallery forest, large trees with sparse understorey. Terrestrial, but nests in trees. Sea-level to 800 m. Co-exists with *C. coquereli*, *C. ruficeps* and *C. cursor*.
Food and Feeding. Diet consists of insects, mainly Lepidoptera, occasionally seeds. Obtains food by walking among dead leaves on forest floor; usually observed in pairs, but also alone or in small family groups.
Breeding. Nest a bowl of twigs, bark and large leaves, lined with leaf petioles, 3–10 m above ground in tree. Eggs 3, dull white; 43.5 x 32 mm.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon in S of range, where it is subject to trapping and hunting, but very common at small (265 ha) Berenty Private Reserve, where well protected and very tame; this reserve is surrounded by completely deforested sisal plantations. Reported to be fairly common where good forest still exists, but such habitat is undergoing marked recession all over Madagascar.

Bibliography. Adamson *et al.* (1982), Appert (1968a, 1968b, 1970, 1972, 1996), Bangs (1918), Benson (1981), Benson *et al.* (1976–1977), Berlioz (1948), Bradt *et al.* (1996), Chouteau (1997), Dee (1986), Delacour (1930, 1932a), Dowsett & Forbes-Watson (1993), Goodman & Ravoavy (1993), Langrand (1985, 1990), Lavauden (1937), Milne-Edwards & Grandidier (1879), Milon *et al.* (1973), Pidgeon & O'Connor (1985), Rand (1936), Salván (1972b), Wilmé *et al.* (1997), Young, G. (1995).

69. Coquerel's Coua

Coua coquereli

French: Coua de Coquerel **German:** Coquerel-Seidenkuckuck **Spanish:** Cúa de Coquerel
Other common names: Coquerel's Madagascar Coucal

Taxonomy. *Coua Coquereli* Grandidier, 1867, Morondava, Madagascar. Monotypic.
Distribution. W Madagascar.

Descriptive notes. 42 cm; 135 g (juvenile). Appears like a small version of *C. gigas*. Adult olive-green above, face black, tail tipped white; tan throat and breast, lower breast rufous, belly dull brown to black; bare skin around eye blue, behind eye pink, bill black. Juvenile duller, face lacks black outline feathers, wing-coverts brown with buff edge, underparts grey-barred whitish, skin around eye slightly feathered, dull blue, iris dark brown, bill flesh, culmen sepia, legs and feet grey. **VOICE.** Loud, clear “kewkiw-kewkewkew”, also grunts, and a high-pitched “ayoo-ew”.

Habitat. Dry forest and humid forest with limited ground cover, to lesser extent second growth, and ranging into edge of SW subdesert. Sea-level to 800 m. Lives alongside *C. gigas* and *C. ruficeps*, and is replaced in S of its range by *C. cursor*.
Food and Feeding. Insects, spiders and berries; fruit form 20% of diet. Feeds mainly on forest floor, on trails, but also in middle layers 1–5 m above ground.

Breeding. Nest a bowl of twigs, small branches, petioles and bark, 2 m above ground in dense bush. Eggs 2, dull white; 33.5 x 25 mm.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common within its rather restricted range in W Madagascar, although it is subject to trapping and hunting. Occurs in several protected areas, e.g. Zombitsy Forest Reserve, and also Ankarafantsika Nature Reserve (62,520 ha) where it is common.

Bibliography. Andriamampianina (1981), Appert (1968a, 1970, 1972, 1980, 1996), Bangs (1918), Benson (1981), Benson *et al.* (1976–1977), Berlioz (1948), Bradt *et al.* (1996), Chouteau (1997), Dee (1986), Delacour (1930, 1932a), Dowsett & Forbes-Watson (1993), Kaudern (1922), Langrand (1985, 1990), Masuda & Ramanampamony (1996), Milne-Edwards & Grandidier (1879), Milon (1952), Milon *et al.* (1973), Rand (1936), Urano *et al.* (1994), Wilmé *et al.* (1997), Young, G. (1995).

70. Red-breasted Coua

Coua serriana

French: Coua de Serre **German:** Rotbrust-Seidenkuckuck **Spanish:** Cúa Pechirrojo
Other common names: Rufous-breasted Madagascar Coucal

Taxonomy. *Coua Serriana* Pucheran, 1845, Madagascar. Monotypic.
Distribution. NE Madagascar, from Zahamena to Sambava; Sambirano.

Descriptive notes. 42 cm; 298 g. Adult dark green-brown above, long blue-black tail, blackish brown below, chest dark rufous; bare skin around eye blue, iris brown, bill black. Juvenile with wing-coverts edged rufous, throat brown-olive (not black), belly olive, tail dull black without blue gloss, skin around eye feathered. **VOICE.** Noisy; repeated loud “koo ha”, a melodic “tee oooo”, also grunts.

Habitat. Undisturbed rain forest. Tends to occur in more open areas and at lower levels than *C. reynaudii*. Sea-level to 1000 m.

Food and Feeding. Berries and fruits; also seeds and insects. Mainly terrestrial, foraging

by walking on ground, or on horizontal branch; walks and runs, seldom flies; feeds beneath flocks of other frugivorous birds, on fruits fallen from trees.

Breeding. Nest a bowl of intertwined branches, 2–4 m above ground in a fern or pandanus. Eggs 2, white.
Movements. Resident.

Status and Conservation. Not globally threatened. Present in several protected areas, e.g. Mantadia National Park (10,000 ha), and recently established (1997) Masoala Peninsula National Park (over 200,000 ha) where large tract of lowland forest still persists. A fairly common species locally, but has a very restricted range and apparently fairly strict habitat requirements. For greater security, populations should be monitored.

Bibliography. Benson (1981), Benson *et al.* (1976–1977), Berlioz (1948), Bradt *et al.* (1996), Dee (1986), Delacour (1932a), Dowsett & Forbes-Watson (1993), Evans, M.I. *et al.* (1992), Langrand (1985, 1990), Milne-Edwards & Grandidier (1879), Milon (1952), Milon *et al.* (1973), Quansah (1988), Rand (1936), Safford & Duckworth (1990), Sganzin (1840), Thompson & Evans (1992), Thompson *et al.* (1987), Thorstrom & Watson (1997), Wilmé *et al.* (1997).

71. Red-fronted Coua

Coua reynaudii

French: Coua de Reynaud **German:** Rotstirn-Seidenkuckuck **Spanish:** Cúa Frentirrojo
Other common names: Reynaud's Coua, Red-fronted Madagascar Coucal

Taxonomy. *Coua Reynaudii* Pucheran, 1845, Madagascar. Monotypic.

Distribution. N & E Madagascar.

Descriptive notes. 38-40 cm; male 128 g, female 163 g. Adult olive-green above, crown rufous, face blackish, long tail green with blue gloss and dark tip; below, darker grey; bare skin around eye blue, iris brown, bill black. Juvenile with head and neck dull rufous-brown, wing-coverts and wing feathers tipped rufous, dull rufous below, bill yellow. Voice. Brief, raucous, plaintive "koo-ah", decreasing in volume, repeated several times.

Habitat. Dense vegetation in undisturbed rain forest and thick second growth, especially in tangles of fallen trees and branches, extends into brushy areas and clearings; also in dry forest in W of range. Terrestrial, but nests in trees. Sea-level to 2500 m.

Food and Feeding. Insects (beetles, grasshoppers, caterpillars), and sometimes lizards; also fruits and seeds. Moves slowly: walks on forest floor and low herbs, walks up sloping trunks, perches in trees.

Breeding. Breeds Aug-Jan. Nest a bowl of dry stalks, palm fibres and large leaves, c. 19 cm in diameter and 9 cm high, with wall 5 cm, inside bowl 10 x 6 cm; 5-7 m above ground in base of first leaves of pandanus or fern. Eggs 2, chalky, dull white; 36 x 28 mm.

Movements. Resident.

Status and Conservation. Not globally threatened. Relatively restricted range, but species apparently remains fairly common, and has been reported from more than 30 localities; more numerous at higher elevations.

Bibliography. Albiguac (1970), Benson *et al.* (1976-1977), Berlioz (1948), Bradt *et al.* (1996), Dee (1986), Delacour (1932a), Dowsett & Forbes-Watson (1993), Langrand (1985, 1990), Milne-Edwards & Grandidier (1879), Milon *et al.* (1973), Pidgeon & O'Connor (1985), Rand (1936), Salvan (1972a), Wilmé *et al.* (1997).

72. Running Coua

Coua cursor

French: Coua coureur **German:** Gelbkohl-Seidenkuckuck **Spanish:** Cúa Corredor
Other common names: Running Coual

Taxonomy. *Coua cursor* Grandidier, 1867, Cape Sainte-Marie and Machikora, Madagascar. Monotypic.

Distribution. SW & S coasts of Madagascar.

Descriptive notes. 34-40 cm; 118 g. Adult pale grey-green above, black line around face, tail grey (not bluish); throat tawny-buff, breast light purplish, belly whitish, flanks grey, undertail grey (not purplish); bare skin around eye blue with prominent pink patch to rear, iris brown, bill black, feet black. Juvenile duller, no black on face, back, rump and wing-coverts edged buff, bill pale. Voice. Loud, clear "kewkewkew-kookoor", also grunts, and ground call "ay-reeyoo".

Habitat. Subarid thorn scrub, spiny desert and dry woodlands with an absence of ground cover, in areas of subdesert brush and calcareous

plateau with low forest bush, but not in areas of *Euphorbia* bush alone. Sea-level to 200 m. Replaces *C. coquereli* in SW Madagascar.

Food and Feeding. Insects. Terrestrial; walks on ground.

Breeding. Breeds in rains; lays in Oct, young juveniles seen in Feb-Mar. Nest a bowl of twigs and bark, lined with leafstalks, 2 m above ground in a bush. Eggs 2, whitish; 34 x 23 mm.

Movements. Resident.

Status and Conservation. Not globally threatened. Appears to be generally uncommon within its small range, although locally fairly common, e.g. near Ifaty. Populations require monitoring.

Bibliography. Appert (1968a, 1970, 1980), Benson *et al.* (1976-1977), Berlioz (1948), Bradt *et al.* (1996), Chouteau (1997), Dee (1986), Dowsett & Forbes-Watson (1993), Langrand (1990), Milne-Edwards & Grandidier (1879), Milon *et al.* (1973), Pidgeon & O'Connor (1985), Rand (1936), Schuurman (1996), van Someren (1947), Wilmé *et al.* (1997).

73. Red-capped Coua

Coua ruficeps

French: Coua à tête rousse **German:** Weißkehl-Seidenkuckuck **Spanish:** Cúa Capirrojo
Other common names: Red-capped Madagascar Coual

Taxonomy. *Coua ruficeps* G. R. Gray, 1846, Madagascar.

Traditionally treated as two subspecies, but both *ruficeps* and *olivaceiceps* were collected at Mampikohy in Dec, in the breeding season, which, together with notable morphological differences, suggests that they may be distinct species. Two subspecies recognized.

Subspecies and Distribution.

C. r. ruficeps G. R. Gray, 1846 - W Madagascar, from Mahajanga W & S to near Morondava.

C. r. olivaceiceps (Sharpe, 1873) - SW Madagascar, from Morondava S to Anony L.

Descriptive notes. 42 cm; 190 g. Adult *ruficeps* light greenish brown above, front and top of head rufous, tail dark brown to purplish with white edge; throat white, lower throat tawny, chest light purplish, belly pale rufous to whitish; skin around eyes blue with black line below, iris dark brown, bill black, feet black. Juvenile dull, crown light brown. Race *olivaceiceps* paler above and below, crown light brown-green; juvenile with back barred, crown grey and slightly barred, wing-coverts tipped buff, breast barred grey on white. Voice. Loud "hug yew yew yew kuh kuh", last 2 notes lower, and loud call "coy coy coy"; also grunts.

Habitat. Dry deciduous forest, thorn scrub, second growth, gallery forest on edge of rivers, forested bottomlands. Sea-level to 850 m.

Food and Feeding. Insects (Orthoptera, beetles), also fruits. Feeds mainly on ground, in more open forest areas; walks on ground.

Breeding. Breeds Nov-Dec. Nest a shallow bowl of thin branches, bark and creepers, 20 cm x 5 cm thick, in a tree. Eggs 2 (1-3), white, tinged dull blue; 35 x 28 mm.

Langrand (1990), Masuda & Ramanampamonjy (1996), Milne-Edwards & Grandidier (1879), Milon (1952), Milon *et al.* (1973), Rand (1936), Salvan (1971), van Someren (1947), Steinbacher (1972), Urano *et al.* (1994), Wilmé *et al.* (1997), Young, G. (1995).

74. Crested Coua

Coua cristata

French: Coua huppé **German:** Spitzschopf-Seidenkuckuck **Spanish:** Cúa Crestado
Other common names: Crested Madagascar Coual

Taxonomy. *Cuculus cristatus* Linnaeus, 1766, Madagascar.

Four subspecies recognized.

Subspecies and Distribution.

C. c. cristata (Linnaeus, 1766) - N & E Madagascar, SW to Mahajanga.

C. c. dumonti Delacour, 1931 - W Madagascar from Mahajanga to Morondava.

C. c. pyropyga Grandidier, 1867 - SW Madagascar between Morondava and Toliara, also S to Amboasary.

C. c. maxima Milon, 1950 - SE Madagascar (near Tolagnaro).

Descriptive notes. 40-44 cm; 136 g. Adult green-grey above, head crested, grey, long tail purplish blue, tipped white; throat grey, breast purplish to rufous, belly white; bare skin around eye blue outlined in black, iris brown, bill black, feet black. Juvenile with grey crown, rufous-edged back and wing-coverts, breast unbarred, feathered skin around eye, bill pale. Race *dumonti* larger on average (but much overlap in size), paler, faint rufous on undertail-coverts, broader white tail tip, and longer crest; *pyropyga* larger, paler, bright rufous on undertail-coverts, broad white tail tip; *maxima* largest and darkest. Voice. Loud, clear

"coy coy coy...", notes separated and decreasing in volume, also grunts.

Habitat. Primary and secondary forest, savanna, brushland, calcareous hills of SW coast, palms, and mangroves. Sea-level to 900 m.

Food and Feeding. Large insects (caterpillars, grasshoppers, beetles, cicadas), also snails, chameleons, and berries, seeds, fruits; takes gum from trees. Arboreal, foraging at higher levels of forest, more than 5m above ground, in canopy of littoral forest.

Breeding. Half-grown chick being fed by adults in Isalo National Park in Nov. Nest a bulky shallow bowl of twigs and rootlets, built by both sexes, 4-15 m above ground in tree. Eggs 2, dull white; 35 x 26.5 mm.

Movements. Resident.

Status and Conservation. Not globally threatened. Widespread, and locally common, persisting in degraded forests. Race *maxima*, however, appears to be exceedingly rare, known from just a single specimen.

Bibliography. Adamson *et al.* (1982), Appert (1970, 1972, 1996), Bangs (1918), Benson *et al.* (1976-1977), Berlioz (1948), Bluntschli (1935, 1938), Bradt *et al.* (1996), Charles-Dominique (1976), Chouteau (1997), Dee (1986), Delacour (1930, 1932a), Dowsett & Forbes-Watson (1993), Langrand (1985, 1990), Lavauden (1937), Masuda & Ramanampamonjy (1996), Milne-Edwards & Grandidier (1879), Milon (1950, 1952), Milon *et al.* (1973), Pidgeon & O'Connor (1985), Rand (1936), Schuurman (1996), van Someren (1947), Steinbacher (1972), Urano *et al.* (1994), Wilmé *et al.* (1997), Young, G. (1995).

75. Verreaux's Coua

Coua verreauxi

French: Coua de Verreaux **German:** Breitschopf-Seidenkuckuck **Spanish:** Cúa de Verreaux
Other common names: Southern Crested Coua, Southern Crested Madagascar Coual

Taxonomy. *Coua Verreauxi* Grandidier, 1867, Cape Sainte-Marie, Madagascar.

Monotypic.

Distribution. SW Madagascar between R Onilahy and R Menarandra, E of Menarandra.

Descriptive notes. 34-38 cm. Adult green-grey above, head with light grey dark-tipped crest, tail glossy blue with white tip; white below; bare skin around eye blue with no black outline, iris yellow to brown, bill thin, black, feet black. Juvenile unknown. Voice. Call "coy coy coy", repeated, like that of *C. cristata* but briefer and more shrill; also loud "quark quark" followed by soft "coo coo", loud call at dusk "trew-ee trew-ee trew-ee" then soft "crow crow crow".

Habitat. Subarid thorn scrub, especially *Euphorbia* and *Didierea* brush, on sandy or calcareous soil. Sea-level to 100 m.

Food and Feeding. Insects, also fruit of *Cassia*. An arboreal forager.

Breeding. Males singing from tree tops in Nov. No further information.

Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered to be near-threatened. Range of present species is complementary to that of *C. cristata*, indicating a recent separation by speciation from it, or exclusion by interspecific competition, or both; the habitat occupied by present species is drier than that of *C. cristata*.
Bibliography. Adamson *et al.* (1982), Andriamampianina (1981), Bangs (1918), Benson (1981), Benson *et al.* (1976-1977), Berlioz (1948), Bradt *et al.* (1996), Dee (1986), Delacour (1932a), Dowsett & Forbes-Watson (1993), Langrand (1990), Lavauden (1937), Milon (1952), Milon *et al.* (1973), Rand (1936), Wilmé *et al.* (1997).

76. Blue Coua
Coua caerulea

French: Coua bleu **German:** Blau-Seidenkuckuck **Spanish:** Cúa Azul
Other common names: Blue Madagascar Coucal

Taxonomy. *Cuculus caeruleus* Linnaeus, 1766, Madagascar. Monotypic.
Distribution. Most of E & NW Madagascar.
Descriptive notes. 48-50 cm; 235 g. Adult dark blue above and below, wings and tail with violet sheen, no white tail tip; bare skin around eye blue, iris brown, bill black, feet black. Juvenile sooty-black on back and lower belly, wings dull blue, tail lacks violet; skin around eye feathered (not bare). **Voice.** Brief trilled "brrree-ee", increasing in volume; loud series of "coy coy coy coy", decreasing in intensity, low-pitched; also a grunt, "kroo kroo".

Habitat. Primary forest, also second growth and dense clove plantations, locally deciduous forest, mangroves. Sea-level to 1800 m.
Food and Feeding. Insects (cicadas, locusts, crickets, bees, beetles, caterpillars), small reptiles (chameleons), crabs, fruits; takes gum resins from trees, rich in polysaccharides. An arboreal coua, active from tree tops to undergrowth, mainly in middle stratum of forest; also runs on ground.
Breeding. Breeds Jul-Dec, mainly in rains. Nest domed, of interlaced dry plant material, 3-5-10 m above ground in dense foliage. Eggs 1, white; 37 x 28-5 mm.

Movements. Resident.
Status and Conservation. Not globally threatened. Common in suitable habitat throughout its range; not dependent on primary forest, as it survives in second growth. Taken for food by local inhabitants.
Bibliography. Albignac (1970), Benson *et al.* (1976-1977), Berger (1953a, 1953b), Berlioz (1948), Bradt *et al.* (1996), Charles-Dominique (1976), Dee (1986), Delacour (1930, 1932a, 1932b), Donnelly (1980), Dowsett & Forbes-Watson (1993), Goodman (1993), Langrand (1985, 1990), Lavauden (1937), Milne-Edwards & Grandidier (1879), Milon (1952), Milon *et al.* (1973), Pidgeon & O'Connor (1985), Rand (1936), Schönewetter (1967), Schuurman (1996), van Someren (1947), Wilmé *et al.* (1997).

Subfamily CENTROPODINAE

Genus *CENTROPUS* Illiger, 1811

77. Bay Coucal

Centropus celebensis

French: Coucal des Célèbes **German:** Celebeskuckuck **Spanish:** Cucal de Célebes
Other common names: Celebes/Celebean Coucal

Taxonomy. *Centropus celebensis* Quoy and Gaimard, 1830, Manado, Sulawesi. Forms a superspecies with *C. unirufus*. Two subspecies recognized.

Subspecies and Distribution.

C. c. celebensis Quoy & Gaimard, 1830 - N Sulawesi.

C. c. rufescens (A. B. Meyer & Wigglesworth, 1896) - C. E. S & SE Sulawesi, Labuan Blanda, Muna and Butung.

Descriptive notes. 44-50 cm. Adult mostly rufous, crown grey, back olive-grey, wings wine-rufous; iris red, bill black, horn at tip, feet black. Juvenile like adult, but paler throat and breast, iris light grey. Race *rufescens* has more rufous on head, back and breast. **Voice.** Call a hollow ranging "koo-ko-ko..." started by one bird and joined by others, and rapidly speeding up. Solitary birds give a repeated "wheeze". **Habitat.** Lowland and lower montane rain forest, in lianas and rattan thickets, ranging through forest edge into open woodland, scrub and dense secondary growth. Recorded from sea-level up to 1000 m.

Food and Feeding. Large insects, especially Orthoptera, locusts, beetles, spiders. Arboreal in behaviour, more like *Phaenicophaeus* than a typical *Centropus*, climbing through lianas and thick foliage, often in small groups; reported to associate frequently with malkohas and troops of macaques. **Breeding.** No information.

Movements. Resident.

Status and Conservation. Not globally threatened. Status and biology very poorly known; research required. Locally common, e.g. in Dumoga-Bone National Park in mid-1980's. Occurrence in wide range of habitats, including secondary growth, suggest species may be relatively adaptable. **Bibliography.** Andrew (1992), Coates & Bishop (1997), Fraser & Henson (1996), Hachisuka (1934), Holmes & Philipps (1996), Jepson (1997), Rozendaal & Dekker (1989), Stresemann (1940), Watling (1983), Wheatley (1996), White & Bruce (1986).

78. Rufous Coucal

Centropus unirufus

French: Coucal roux **German:** Bambuskuckuck **Spanish:** Cucal Rufo

Taxonomy. *Pyrrhocentor unirufus* Cabanis and Heine, 1863, Luzon.

Forms a superspecies with *C. celebensis*. Monotypic.

Distribution. Luzon, Polillo and Catanduanes (N Philippines).

Descriptive notes. 38-42 cm; 184 g. Adult rufous, bare skin around eye yellow, iris light brown, bill greenish with yellow tip, feet black. Juvenile as adult, but white hair-like down on head, bill black. **Voice.** Call a shrill, plaintive "kaow" when separated from its mate.

Habitat. Hill forest in matted undergrowth, tangled lowland forest with bamboo, usually on or near ground, also into trees.

Food and Feeding. Not known.

Breeding. No information.

Movements. Resident.

Status and Conservation. Not globally threatened. Currently considered near-threatened.

Situation may be somewhat precarious because of restricted range and the loss of forest habitat therein. The species is uncommon and local. Present in Angat forest near Manila.

Bibliography. Collar *et al.* (1994), Danielsen *et al.* (1994), Delacour & Mayr (1946), Dickinson *et al.* (1991), DuPont (1971), Gilliard (1950b), Gonzales (1983), Goodman & Gonzales (1990), Hachisuka (1934), Hornskov (1992), McGregor (1909-1910), Poulsen (1995).

79. Black-faced Coucal

Centropus melanops

French: Coucal à face noire **German:** Maskenkuckuck **Spanish:** Cucal Carinegro

Taxonomy. *Centropus melanops* Lesson, 1830, Java; error = Mindanao.

Race *banken* doubtfully valid. Two subspecies normally recognized.

Subspecies and Distribution.

C. m. Banken Hachisuka, 1934 - Bohol, Leyte, Biliran and Samar (EC Philippines).

C. m. melanops Lesson, 1830 - Nipah, Dinagat, Siargao, Mindanao and Basilan (SE Philippines).

Descriptive notes. 42-48 cm; male 213 g, female 214 g. Adult black above, head, neck and breast pale buff, face black, wings brown, tail glossy black, lower breast and belly black; iris red, bill black, feet black. Female larger. Juvenile as adult. Race *banken* has slightly more black on forehead. **Voice.** Not described.

Habitat. Forests, in tree tops and tangled undergrowth, second growth. Lowlands to 1200 m.

Food and Feeding. Not described.

Breeding. Nest undescribed. Eggs white; 37 x 29 mm.

Movements. Resident.

Status and Conservation. Not globally threatened. This was a common species in Mindanao 60 years ago, but the forests have now almost completely disappeared; still common at PICOP, near Bislig. It seems likely that further forest destruction will lead to this coucal's inclusion on the list of endangered species.

Bibliography. Delacour & Mayr (1946), Dickinson *et al.* (1991), DuPont (1971), DuPont & Rabor (1973b), Dutson *et al.* (1995), Hachisuka (1934), McGregor (1909-1910), Parkes (1971a), Rand & Rabor (1960), Schönwetter (1967).

80. Sunda Coucal

Centropus nigrorufus

French: Coucal noirou **German:** Sundakuckuck **Spanish:** Cucal de la Sonda
Other common names: Javan Coucal

Taxonomy. *Cuculus nigrorufus* Cuvier, 1817, Java. Monotypic.

Distribution. Java.

Descriptive notes. 46 cm. Adult glossy black above with stiff hackles, purplish gloss on mantle, wings rufous with blackish tips to flight-feathers and upperwing-coverts, long black tail; purplish-glossed black below; iris red, bill black, feet black. Female slightly larger. Juvenile as adult. **Voice.** Not described.

Habitat. Mangrove and other swamps, especially in estuaries, thickets and elephant grass in coastal lowlands, palm vegetation behind mangroves; possibly also inland grass swamps.

Food and Feeding. Insects (grasshoppers, beetles, hairy caterpillars), frogs.

Breeding. Nest undescribed. Eggs white; 39 x

31 mm.

Movements. Resident.

Status and Conservation. **VULNERABLE.** Confined to Java, where it occurs in fragmented small local populations, and remains locally common in remnant coastal wetlands. It is possibly threatened as its habitat is being converted to fish and shrimp ponds and agricultural land, as a result of which present species is replaced by *C. bengalensis*. An old record from inland teak forest and sightings in scrub away from coastal wetlands, together with its appearance in local bird markets, suggest, however, that it is likely to be more widespread and that it occurs in a greater variety of habitats than previously recognized. This coucal may possibly be present also in Sumatra, from where there is an old specimen of doubtful origin, as well as recent sight reports.

Bibliography. Andrew, P. (1988, 1990, 1992), Collar & Andrew (1988), Collar *et al.* (1994), Finsch (1902), Hellebrekers & Hoogerwerf (1967), Holmes & Nash (1989), Hoogerwerf (1948a, 1970), Jepson (1997), Kuroda (1933-1936), MacKinnon (1988), MacKinnon & Philipps (1993), Neumann (1902), Robson (1989, 1991b), Sody (1989), Sujatnika & Jepson (1995), Sujatnika *et al.* (1995), Wheatley (1996).

81. Buff-headed Coucal

Centropus milo

French: Coucal à tête fauve **German:** Bläkopfkuckuck **Spanish:** Cucal Milo

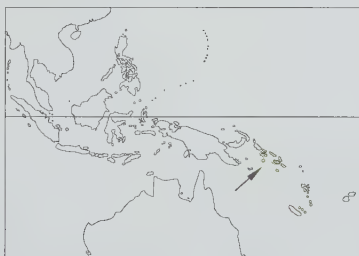

Taxonomy. *Centropus Milo* Gould, 1856, Guadalcanal, Solomon Islands.

Two subspecies recognized.

Subspecies and Distribution.

C. m. albidiventris Rothschild, 1904 - Vella Lavella, Kolombangara, Near Georgia, Gizo and Rendova (WC Solomons).

C. m. milo Gould, 1856 - Guadalcanal and Florida Is (S Solomons).

Descriptive notes. 60-68 cm. Adult black except for buff foreparts; iris red to red-brown, bill black, basal skin deep grey, feet blue-grey. Juvenile brown, mottled with black, wings and long tail rufous, barred blackish, iris grey to brown, bill brown, lower mandible pale horn to whitish. Race *albidiventris* wholly whitish below. **Voice.** A "sawing" or "snoring" noise; pair members alternate "urrrh" with "uh"; solitary birds give a guttural "kkkkow...kkkk...kk...kk", a throaty bark, and a deep churring "argh-a-argh", juveniles a stuttering cough.

Habitat. Lowland, hill and mist forest; primary and secondary forest and thickets in gardens.

Food and Feeding. Insects, including stick insects, grasshoppers, beetles, pupae; giant centipedes. Feeds mainly on the ground, but also occasionally ascends into trees.

Breeding. No information.
Movements. Resident.

Status and Conservation. Not globally threatened. Common on New Georgia, where can be found in secondary growth and near human habitation. Little known: research and survey work required.
Bibliography. Blaber (1990), Cain & Galbraith (1956), Dahl, (1986), Hartert (1925b), Sibley (1951).

82. Goliath Coucal

Centropus goliath

French: Coucal goliath **German:** Goliathkuckuck **Spanish:** Coucal Goliat
Other common names: Giant/Large Coucal

Taxonomy. *Centropus goliath* Bonaparte, 1850, Halmahera.
Forms a superspecies with *C. violaceus* and *C. menbeki*. Monotypic.

Distribution. N Moluccas, on Ternate, Morotai, Halmahera, Tidore, Bacan and Obi.

Descriptive notes. 62-70 cm. Adult black, with bluish wings and tail, white patch on greater wing-coverts; on Halmahera, also a whitish morph, with buffish on head, and occasional pied individuals; iris dark brown, bill black, feet black. Juvenile black above, wing-coverts with white patch, head, neck and underparts chestnut with whitish diamond-shaped streaks, belly blackish (no known pale morph juveniles). **VOICE.** No information available.

Habitat. Forested areas of all types, including larger patches of scrub at edge of agricultural land on Halmahera; primary and logged forest to 250 m on Bacan.

Food and Feeding. No information on diet. Feeds in lower forest subcanopy to 12 m, as well as in understorey.

Breeding. Little information. Nestling with long white hair-like down, especially on head.

Movements. Resident.

Status and Conservation. Not globally threatened. Common and conspicuous on Halmahera, but not recorded recently on smaller islands of Obi and Ternate.

Bibliography. Andrew (1992), van Bemmel (1948), Coates & Bishop (1997), Hartert (1903a), Jepson (1997), Lambert (1994b), Lambert & Young (1989), Sujatnika *et al.* (1995), Wheatley (1996), White & Bruce (1986).

83. Violaceous Coucal

Centropus violaceus

French: Coucal violet **German:** Purpukuckuck **Spanish:** Cocal Violáceo
Other common names: Giant Forest Coucal

Taxonomy. *Centropus violaceus* Quoy and Gaimard, 1830, Carteret Harbor, New Ireland.
Forms a superspecies with *C. goliath* and *C. menbeki*. Monotypic.

Distribution. New Britain and New Ireland.

Descriptive notes. 64 cm; 500 g. Adult black with violet sheen, tail broad, bare skin around eye greyish, eye-ring black, iris red, bill black, feet pale slaty-horn. Juvenile dull black above, wings and tail glossed purple, underparts downy, sooty-grey, iris light grey. **VOICE.** Deep, hollow booming notes and loud booming duets.

Habitat. Occurs in primary forest from lowlands up to 950 m.

Food and Feeding. Large insects, including stick insects almost 18 cm long; also frogs and tiny snails. Active in limbs of trees and vines.

Breeding. Nest a loose structure of twigs, built in top of a tall tree. Eggs 3, white; 42.5 x 34

mm. Nestling has black skin, long white feather sheaths on head and back, mouth purplish pink with white Y-shaped ridge on palate, white edge of tongue, feet bluish grey.

Movements. Resident.

Status and Conservation. Not globally threatened. Virtually no information available on status, as range comprises zone of extremely limited ornithological exploration; species considered to be widely but thinly distributed in suitable habitat throughout range in mid-1980's.

Bibliography. Coates (1985), Dahl (1986), Diamond (1972b), Eastwood (1995c), Gilliard (1961), Gilliard & LeCroy (1967a), Hariert (1925b), Orenstein (1976), Schönwetter (1967).

84. Greater Black Coucal

Centropus menbeki

French: Coucal menébeki **German:** Mohrenkuckuck **Spanish:** Cocal Menebiki
Other common names: Greater Coucal(!)

Taxonomy. *Centropus Menbeki* Garnot, 1828, New Guinea = Manokwari.

Forms a superspecies with *C. goliath* and *C. violaceus*. Original spelling is *menbeki*, although listed by Lesson and Garnot in 1829 as "*menebiki*", based on a local Papuan word. Three subspecies recognized.

Subspecies and Distribution.

C. m. menbeki Garnot, 1828 - New Guinea, W Papuan islands and Numfor I.

C. m. jobiensis Stresemann & Paludan, 1932 - Yapen I.

C. m. aruensis (Salvadori, 1878) - Aru Is.

Descriptive notes. 60-67 cm; race *jobiensis* male 480 g and female 553 g, race *menbeki* male 293 g. Adult huge, glossy black, with long tail, iris red, bill whitish with black base, legs black. Juvenile dull, blackish, with narrow rufous bars at base of tail, iris tan or orange. Race *menbeki* darker above, smaller; *aruensis* dark purplish black above; *jobiensis* less purplish, more greenish. **VOICE.** Low-pitched, resonant booming hoots in staccato; single-note "oodle", also pairs of "hoo hoo", and descending series of "Uh-oo-oo-oo-oo-oh"; a grunt followed by a dry rattle. Calls at night.

Habitat. Forest, forest edge, shrub and lower middle storeys. Sea-level to 800 m.

Food and Feeding. Small vertebrates (snakes, frogs, small birds), arthropods, large insects (grasshoppers, cicadas, caterpillars). Feeds on ground, where movements clumsy, and in vines; hops up tree trunks, switching tail from side to side.

Breeding. Oviduct egg in Apr; recently fledged young Jan, Oct. Nest a large mass of leaves, in pandanus, in wet season. Oviduct egg white; 37 x 30 mm.

Movements. Resident.

Status and Conservation. Not globally threatened. A widely distributed species in New Guinea, but apparently uncommon throughout. Approximate density estimated at 1 bird/10 ha.

Bibliography. Andrew (1992), Beehler (1978b), Beehler, Burg *et al.* (1994), Beehler, Pratt & Zimmerman (1986), Bell (1982), Burrows (1993), Coates (1985), Diamond (1972a), Eastwood (1995b), Gilliard & LeCroy (1966), Gregory (1995a, 1995b), Hartert (1930), Hiaso *et al.* (1994), Mayr & Meyer de Schauensee (1939b), Mayr & Rand (1937), Rand (1942a, 1942b), Rand & Gilliard (1967), Ripley (1964), Stoner (1937).

85. Pied Coucal

Centropus ateralbus

French: Coucal atralbin **German:** Weißkopfkuckuck **Spanish:** Cocal Blanquinegro
Other common names: White-necked Coucal

Taxonomy. *Centropus ateralbus* Lesson, 1826, New Ireland.
Monotypic.

Distribution. New Britain and New Ireland.

Descriptive notes. 44-48 cm; male 330 g, female 342 g. Adult black, face and flight quills glossy purplish blue, with neck and upper breast and patch on wing white (or brownish white or pearly-grey instead of white). Also several colour morphs, including: all white with black forehead and lores; all white on head and mantle; black only on crown; all black but for white wing patch. Iris red, bill black, legs slaty-blue to black. Immature blackish, with white feathers on neck and wing. Juvenile with anterior half of body striped buff or rufous, iris grey, legs blue-grey. **VOICE.** Alarm a short "chit"; song a duet by two birds sounding like two hollow metal drums, "soo-hoo", rising in pitch and lasting up to 17 sec; also a nasal "k-k-k-naahh".

Habitat. Forest, forest edge, secondary forest, strand vegetation by shore cultivations, near forest floor. Sea-level to 1200 m.

Food and Feeding. Insects, including large stick insects, also other small animals. Active, clumsy.

Breeding. Nest a hollow or chamber, lined with green vegetation. Eggs 2, whitish; 41 x 33 mm.

Movements. Resident.

Status and Conservation. Not globally threatened. True status very poorly known, but species appears to be uncommon in uplands of New Britain. Research and survey work required.

Bibliography. Beehler (1978a), Coates (1985), Dahl (1986), Diamond (1972b), Eastwood (1995c), Gilliard & LeCroy (1967a), Halliday (1992), Meyer (1936), Orenstein (1976), Schönwetter (1967).

86. Pheasant Coucal

Centropus phasianinus

French: Coucal faisán **German:** Fasanspornkuckuck **Spanish:** Cocal Faisán

Taxonomy. *Cuculus phasianinus* Latham, 1801, New South Wales. Forms a superspecies with *C. spilopterus*, *C. bernsteini* and *C. chalybeus*. Form *mui* of Timor may possibly represent a separate species, but to date known only from a single specimen. Six subspecies recognized.

Subspecies and Distribution.

C. p. mui Mason & McKean, 1984 - Timor.

C. p. propinquus Mayr, 1937 - N New Guinea.

C. p. nigricans (Salvadori, 1876) - SE New Guinea and Yule I.

C. p. thierfelderi Stresemann, 1927 - S New Guinea and NW Torres Strait islands.

C. p. melanurus Gould, 1847 - N & NW Australia.

C. p. phasianinus (Latham, 1801) - E Australia.

Descriptive notes. 53-80 cm; in N New Guinea male 205 g and female 300 g, in Australia male 337 g and female 495 g. Long-tailed pheasant-like bird. Adult male all black, streaked and barred brown above, wing with inner webs rufous, outer webs barred buff, black and rufous-brown; iris red, bill black, feet blackish. Female larger, iris orange to yellow. Non-breeding plumage (Australia) rufous above with straw-coloured streaks, head and underparts buff; iris pale brown (female whitish), bill pale horn. Juvenile more fawn, paler below, iris brown, bill brown to pale below. Race *nigricans* has yellowish underwing bars narrower than black bars;

propinquus similar, but smaller; *thierfelderi* has rufous bars on underwing as wide as or wider than black bars; *melanurus* larger than *phasianinus*, wider black bars on rectrices; *mui* extensively white. **VOICE.** Dull booming series of "hoo" notes, falling and then rising in pitch, "coo-coo-coo-coo-coo-coo-coo-coo", accelerates in tempo; often duets; also harsh scolding calls, and a hiss in alarm.

Habitat. Dense riverine vegetation, long grass, rank herbage, coastal heathlands, margins of swamps, canefields, lantana and pandanus thickets, mangroves, secondary forests, spinifex in sandstone country. Lowlands, not in New Guinea highlands.

Food and Feeding. Arthropods, especially insects (grasshoppers, stink-bugs, mantids, stick insects, caterpillars), *Sesarma* mangrove mud crabs, snails; frogs, lizards, nestling birds, small mammals including rodents and bandicoots. Skulking, spends much time on ground, clammers in thick vegetation; searches for food by walking in low dense vegetation and ground cover, then runs down its prey.

Breeding. In Australia, breeds Sept-May in Queensland, Nov-Mar in Kimberley Division, Dec-Apr in Northern Territory. Nest a covered mass of grass, lined with leaves, open at either end; begun as platform, then blades and stems drawn together to form a cover, then nest-lining added, sometimes with an extension tube; in tussock near ground. Eggs 3-5 (2-7), white, stained brown; 38 x 29 mm; incubation 15 days, by both sexes, starts with first egg, green leafy twigs added through period. Nestling black with long white hair-like down, mouth red, tongue red with black tip; fed by both sexes, eyes open at 7 days, may then leave nest if disturbed, short-tailed young seen carried by feet of parent in flight; fledging normally 17 days (hand-reared bird), young do not return to nest, hair-like down disappears within a week of fledging; independent at 40 days. Female may lay several clutches in a season.

Movements. Resident.

Status and Conservation. Not globally threatened. Common near the coast, uncommon in semi-arid areas, scarce in arid zone. This species has become uncommon in Pilbara Region, Western Australia, where earlier it was moderately common. Population density in woodland of S New Guinea calculated at c. 0.1 bird/ha.

Bibliography. Beehler *et al.* (1986), Bell (1969b, 1970a, 1982, 1984a), Beruldsen (1980), Blakers *et al.* (1984), Coates (1985), Coates & Bishop (1997), Ford (1987b), Frauca (1967, 1974), Hall (1974), Hartert (1930), Hicks & Restall (1992), Hindwood (1942, 1957), Mackness (1979), Mason & McKean (1984), Mayr (1937), Mayr & Rand (1937), Mees (1982a), Mills (1987b), Pratt (1972), Rand & Gilliard (1967), Rose (1997a), Rutgers & Norris (1972), Serventy & Whittell (1976), Storr (1977, 1980, 1984a, 1984b), Strahan (1994), Taplin & Beurteaux (1992), White & Bruce (1986).

87. Kai Coucal
Centropus spilopterus

French: Coucal des Kai **German:** Kaikuckuck **Spanish:** Cucal de las Kai

Taxonomy. *Centropus spilopterus* G. R. Gray, 1858, Kai Islands.
Forms a superspecies with *C. phasianinus*, *C. bernsteini* and *C. chalybeus*. Monotypic.

Distribution. Kai Is (SE Moluccas).

Descriptive notes. 60 cm. Adult black, feather shafts glossy black, long tail glossed green, iris red, bill black, feet black. Female larger. Juvenile barred dark brown and buff, bill reddish brown, iris reddish brown. Voice. Not known.

Habitat. Insufficient information.

Food and Feeding. Unknown.

Breeding. Breeding season: nestling in Jul. Nest not described. Eggs white; 36 x 27 mm. Nestling similar to juvenile, often barred whitish, iris brown, bill black.

Movements. Resident.

Status and Conservation. Not globally threatened. Currently considered near-threatened. Very

restricted range, with no details available about relative densities. Very little is known about this coucal, and even basic habitat preferences remain to be established. Considerable field research is required.

Bibliography. Andrew (1992), Coates & Bishop (1997), Collar *et al.* (1994), Hartert (1903b), Jepson (1997), Sujatnika *et al.* (1995), Wheatley (1996), White & Bruce (1986).

88. Lesser Black Coucal
Centropus bernsteini

French: Coucal de Bernstein **German:** Bernsteinkuckuck **Spanish:** Cucal de Bernstein
Other common names: Black Scrub/Bernstein's Coucal

Taxonomy. *Centropus Bernsteini* Schlegel, 1866, New Guinea.
Forms a superspecies with *C. phasianinus*, *C. spilopterus* and *C. chalybeus*. Two subspecies recognized.

Subspecies and Distribution.

C. b. bernsteini Schlegel, 1866 - W & C New Guinea E to Simbang and the Sattelberg.

C. b. manam Mayr, 1937 - Manam I (NE New Guinea).

Descriptive notes. 46-52 cm; male 140 g, female 180 g. Adult black, glossed green above, iris dark brown, bill black. Juvenile barred rufous above, wings and tail narrowly barred buff to pale chestnut, throat whitish, neck marked with chestnut-brown, central belly grey with dark bars, rest of underparts blackish brown with narrow pale barring. Race *manam* larger. Voice. Three hoots, "woop woop woop", on descending scale, sometimes in longer series; pairs often duet.

Habitat. Scrub, tall cane grass, rank vegetation. Sea-level to 500 m, rarely to 900 m.

Food and Feeding. Unknown.

Breeding. Nest a domed mass of cane grass, with side opening, placed in grass. Eggs 2, white; 32 x 26 mm.

Movements. Resident.

Status and Conservation. Not globally threatened. This coucal is not uncommon in second growth and cane grass, but is shy and difficult to observe. Poorly known in all aspects; research required.

Bibliography. Andrew (1992), Anon. (1994b), Bailey (1992a), Beehler (1978b), Beehler *et al.* (1986), Burrows (1993), Coates (1985), Gilliard & LeCroy (1966), Gregory (1995a, 1995b), Hartert (1930), Jepson (1997), Maxwell (1938), Mayr (1937), Rand (1942b), Rand & Gilliard (1967), Ripley (1964), Rothschild & Hartert (1915), Rutgers & Norris (1972).

89. Biak Coucal
Centropus chalybeus

French: Coucal de Biak **German:** Biakuckuck **Spanish:** Cucal de Biak

Taxonomy. *Nesocentor chalybeus* Salvadori, 1875, Biak.
Forms a superspecies with *C. phasianinus*, *C. spilopterus* and *C. bernsteini*. Monotypic.

Distribution. Biak I in Geelvink Bay, N New Guinea.

Descriptive notes. 44-46 cm. Adult black, glossed purple above, spiny feathers on foreparts, iris yellow, bill black (straighter than that of *C. menbeki*). Juvenile washed rufous, unbarred. Voice. Loud: a hollow note, repeated, a descending series of upslurred hoots going up and down in waves, a harsh rasp, and a repeated "bup".

Habitat. Primarily lowland forest, also second growth.

Food and Feeding. Diet unknown. Feeds on ground, also in vines and in trees; noisy on ground, where hops; flies awkwardly, like other coucals.

Breeding. No information.

Movements. Resident.

Status and Conservation. Not globally threatened. Currently considered near-threatened. According to one report, hunting and habitat destruction have severely reduced numbers in S of island, so main stronghold of species would appear to be forests of Supiori. Very poorly known; research required.

Bibliography. Andrew (1992), Beehler *et al.* (1986), Bishop (1982), Collar *et al.* (1994), Jepson (1997), Mayr & Meyer de Schauensee (1939a), Rand & Gilliard (1967), Sujatnika *et al.* (1995).

90. Short-toed Coucal
Centropus rectunguis

French: Coucal de Strickland **German:** Kurzspornkuckuck **Spanish:** Cucal de Strickland

Taxonomy. *Centropus rectunguis* Strickland, 1847, Malacca.
Monotypic.

Distribution. Peninsular Malaysia, Sumatra and Borneo.

Descriptive notes. 43 cm; male 160 g, female 167 g. Similar to *C. sinensis*, but smaller and shorter-tailed. Adult black, glossed purplish blue, with chestnut wings, black tail, iris red, bill black, feet black. Female slightly larger. Juvenile barred blackish and rufous-buff above, upper head brown-streaked chestnut, wings chestnut, coverts with black bars, tail black with fine white bars, chin to belly dark brown with dull white barring (some are nearly black below, others brown), iris red, bill brown, paler below, feet blackish. Voice. Four to five resonant booming notes, "buup", on descending scale, like those of *C. sinensis* but deeper and

slower, more hoarse and resonant; also rapid series of resonant, rising notes at dusk.

Habitat. Lowland closed-canopy forest (alluvial forest, peat swamp forest, riverine forest); also reported in coastal scrub, casuarinas, long grass, dense jungle. Lowlands to 1700 m.

Food and Feeding. Presumably mainly insects, as in other coucals.

Breeding. Nest undescribed. Eggs white; 37 x 30 mm; no information on clutch size.

Movements. Resident.

Status and Conservation. Not globally threatened. Currently considered near-threatened. May be at risk owing to habitat specialization, low colonizing ability, and possible competition from other species of coucal. In Sumatra, survives in undisturbed primary and selectively logged forest and at forest edge; reported as occurring in tall grass in Borneo, from where only 4 specimens are known.

Bibliography. Andrew (1992), Chasen (1939), Collar & Andrew (1988), Duckworth & Kelsh (1988), Gibson-Hill (1949), Holmes (1995a, 1996), Holmes & Burton (1987), Jepson (1997), MacKinnon & Phillippis (1993), van Marle & Voous (1988), Medway & Wells (1970, 1976), Mees (1986), Robson (1991a), Schönwetter (1967), Smythies (1981), Wells (1972b), Wheatley (1996).

91. Black-hooded Coucal
Centropus steerii

French: Coucal de Steere **German:** Mindorokuckuck **Spanish:** Cucal de Mindoro
Other common names: Steere's Coucal

Taxonomy. *Centropus steerii* Bourns and Worcester, 1894, Mindoro.
Monotypic.

Distribution. Mindoro (NC Philippines).

Descriptive notes. 46 cm. Adult head black, glossed blue green, neck, back and wings brownish black, breast and belly dark brown, iris brown, bill black. Female larger. Juvenile as adult, but lacks hackles, back feathers soft-webbed, chin and throat brown (not black), bill pale and not so deep as adult's. Voice. Not known.

Habitat. Primary forest. Lowlands to 750 m.

Food and Feeding. Unknown.

Breeding. Unknown.

Movements. Resident.

Status and Conservation. CRITICALLY ENDANGERED. This coucal is close to extinction in its highly restricted range, where it is threatened by the widespread loss of primary forest in the lowlands. It is likely to become extinct within 10-20 years. Where its forest habitat has been degraded, it has been replaced by *C. viridis*. In 1990's, present species has been observed only at Malpalon and Sablayan, with only *C. viridis* noted at all other forest sites.

92. Greater Coucal

Centropus sinensis

French: Grand Coucal **German:** Heckenkuckuck **Spanish:** Cucal Chino
Other common names: Common/Large Coucal, Common Crow-pheasant, Lark-heeled Cuckoo

Taxonomy. *Polophilus sinensis* Stephens, 1815, Ning Po, China. Forms a superspecies with *C. andamanensis*, the two sometimes being treated as conspecific. Birds from Malaysia, Sumatra, Borneo and Palawan are sometimes placed together in a separate race *eurycerus*. Race *anonymus* sometimes misspelt “*anonymous*”. Six subspecies recognized.

Subspecies and Distribution.
C. s. sinensis (Stephens, 1815) - Pakistan (Sind, Punjab) and Kashmir through N India (Himalayas and Gangetic Plain) to Bengal, Sikkim and N Assam and foothills in Bhutan, and on to S China (Guanxi, Zhejiang, Fujian).
C. s. parroti Stresemann, 1913 - peninsular India and Sri Lanka.
C. s. intermedius (Hume, 1873) - Bangladesh and S Assam E through Myanmar to SC China (S Yunnan and Hainan), and S to Thailand, Indochina and Peninsular Malaysia.
C. s. bubutus Horsfield, 1821 - Sumatra, Nias and Mentawai Is to Borneo and W Philippines (Balabac, Cagayan Sulu, Palawan), and S to Java and Bali.
C. s. anonymus Stresemann, 1913 - SW Philippines (Basilan, Sulu Is).
C. s. kangeanensis Vorderman, 1893 - Kangean Is.

with throat grey, breast mottled grey). Voice. Song a series of deep “hoop” notes, full song running down and up the scale, followed by more “hoop” notes: a “tok”, also a harsh scold, “skaaah”.
Habitat. Secondary forest, tall grassland, thickets, bamboo, scrub near cultivation, paddyfields, cover near streams and swamps, mangroves, gardens; widespread, except in dense primary forest. Lowlands, in hills to 1200 m, occasionally to 2100 m.
Food and Feeding. Small mammals (mice, hedgehog), lizards, snakes, frogs; insects (caterpillars, grasshoppers, katydids, beetles, larvae of rhinoceros beetles); also centipedes, scorpions, spiders, crabs, snails, slugs, eggs and nestlings of small birds, fruits and seeds. Terrestrial and skulking, stalks, walks, hops and runs in pursuit of prey; creeps through shrubs and robs birds’ nests; prowls on mud banks of rivers near water’s edge.
Breeding. Breeds in rains: mainly Jun-Sept in N India, practically all year in peninsular India and Sri Lanka (peak Mar-Apr, Sri Lanka), from Apr in Myanmar, nests with eggs Jan-May in Peninsular Malaysia. Monogamous, occurs in pairs. Nest a large globular ball of twigs and leaves, or coarse grass, with lateral entrance, concealed in thick bush or low in thorny tree or in rice fields. Eggs 2-4 (India), 2-3 (Sri Lanka), 2 (Malaysia), chalky white, stained by nest dirt; 36 x 28 mm (India), 34 x 29 mm (Sri Lanka), 38 x 30 mm (Java), 29 x 24 mm (N Borneo). Both sexes raise the young.
Movements. Resident. Occasionally disperses; one heard once on Serfung, Krakatau, in 1919, years after volcanic activity exterminated all landbirds. Flight slow and laboured, alternates flaps and glides.
Status and Conservation. Not globally threatened. Common almost everywhere throughout its expansive range, and very common in some areas, notably in much of India and Thailand. In Borneo, nestling coucals are taken by man for purported medicinal purposes.

93. Brown Coucal

Centropus andamanensis

French: Coucal des Andaman **German:** Andamanenkuckuck **Spanish:** Cucal de Andamán
Other common names: Andaman Coucal

Taxonomy. *Centropus andamanensis* Beavan, 1867, Andaman Islands. Forms superspecies with *C. sinensis*, with which sometimes treated as conspecific. Species name sometimes erroneously given as *andamenensis*. Monotypic.
Distribution. Andaman Is, and neighbouring Table I, Great Coco I, Little Coco I (Myanmar).
Descriptive notes. 45-48 cm; 234 g. Adult grey-buff on head, mantle and underparts, back rufous-purple, wings rufous-purple with tip darker bronze, wing-linings grey-buff, tail bronzy-purple; iris red to red-brown to yellow, bill black, feet black. Female larger. Plumage

like pale morph of *C. sinensis kangeanensis*, but darker, belly more dusky or sooty. Juvenile finely barred above and below. Voice. A deep “boom, boom, boom”.
Habitat. Forests, cultivations, especially sugarcane, paddyfields, mangrove swamps.
Food and Feeding. Grasshoppers, presumably also other insects and small arthropods.
Breeding. Breeds Feb-Jul. Nest a dome of twigs, grass and leaves. Eggs 2-3, chalky white; 35 x 28 mm.
Movements. Resident.
Status and Conservation. Not globally threatened. Currently considered near-threatened. Restricted distribution, but within this area species is common, and is the most readily seen endemic bird in the Andaman Is.
Bibliography. Ali & Ripley (1981), Collar *et al.* (1994), Ripley (1982), Ripley & Beehler (1989), Tikader (1984).

94. Philippine Coucal

Centropus viridis

French: Coucal vert **German:** Grünkuckuck **Spanish:** Cucal Filipino
Other common names: Green Coucal

Taxonomy. *Cuculus viridis* Scopoli, 1786, Antigua, Panay. Four subspecies recognized.
Subspecies and Distribution.
C. v. major Parkes & Niles, 1988 - Babuyan Is (N Philippines).
C. v. viridis (Scopoli, 1786) - Luzon, Mindanao, Masbate, Bohol, Negros, Cebu, Leyte, Samar and Catanduanes (N & E Philippines).
C. v. mindoroensis (Steere, 1890) - Mindoro and Semirara Is (NC Philippines).
C. v. carpenteri Mearns, 1907 - Batan group (E Philippines).

Descriptive notes. 41-43 cm; male 113 g, female 150 g (*viridis*), male 149 g, female 209 g (*carpenteri*), male 162 g, female 218 g (*major*). Adult *viridis* black above and below, glossed blue to green, wings chestnut; bare skin around eye grey, iris red, bill grey to black; also an uncommon white morph in Luzon, with dull yellowish bill. Female larger. Juvenile black or blackish above, streaked buff, wings chestnut, barred blackish, long tail unbarred bronze-green (tip sometimes barred), rectrices narrow, underparts black with narrow buff bars. 1st-winter plumage with head rufous-grey with light buff shaft streaks, wings rufous to vinaceous, underparts grey, upper breast streaked, and (especially) throat pale with buff shaft streaks, tail bronze-green, below mottled grey. Race *major* larger; *mindoroensis* and larger *carpenteri* melanistic, with blackish wings. Voice. “cuc, cuc, ...” or “Cha-gook-chook”.
Habitat. Tall grass, mixed cultivation, disturbed second growth, thickets, from lowlands up to 2000 m.
Food and Feeding. Insects, including beetles and caterpillars. Usually feeds on or near the ground.
Breeding. Breeding records Apr-Jul. Nest a bulky globe of grass, entrance on one side, in bed of giant grass, c. 1-1.5 m above ground. Eggs 3, dull white and chalky; 31-24 x 25-21 mm; incubation c. 2 weeks; chick has dark skin.
Movements. Resident.
Status and Conservation. Not globally threatened. Common within its range, and evidently adaptable; its ability to accept man-altered habitats is clearly an advantage in terms of its continued survival.
Bibliography. Alcalá & Alviola (1970), Alcalá & Sanguila (1969), Brooks, Dutson *et al.* (1995), Danielsen *et al.* (1994), Delacour & Mayr (1946), Dickinson *et al.* (1991), DuPont (1971), DuPont & Rabor (1973b), Gilliard (1950b), Goodman & Gonzales (1990), Goodman *et al.* (1995), Hachisuka (1934), Mees (1971), Parkes (1957b, 1965b, 1973), Parkes & Niles (1988), Potter (1953), Rabor (1977), Rand & Rabor (1960), Ross & Ramos (1992), Wolfe (1938).

95. Madagascar Coucal

Centropus toulou

French: Coucal toulou **German:** Tulukuckuck **Spanish:** Cucal Malgache
Other common names: Malagasy Coucal, Black Coucal

Taxonomy. *Cuculus Toulou* P. L. S. Müller, 1776, Madagascar. Sometimes regarded as conspecific with *C. grillii*, but voices of the two differ; also occasionally considered to include *C. bengalensis*. Extinct population of Assumption I sometimes awarded separate race, *assumptionis*. Two subspecies normally recognized.
Subspecies and Distribution.
C. t. toulou (P. L. S. Müller, 1776) - Madagascar.
C. t. insularis Ridgway, 1894 - Aldabra; formerly also Assumption I.

call, also a sudden guttural “coogoo”.

Descriptive notes. 40-46 cm; male 139 g, female 189 g (*toulou*), male 117 g, female 131 g (*insularis*). Adult black, but for unbarred rufous-chestnut middle and lower back and wings, tail glossy black, iris red, bill black, feet grey. Non-breeding plumage striped tan above, black areas with buffy shaft streaks, wings unbarred, bill rose-brown. Juvenile similar to non-breeding adult, more barred above and with short shaft streaks, wings and tail barred, belly slightly barred and with shaft streaks. Race *insularis* paler below in non-breeding plumage. Voice. Muffled “toogoo toogoo toogoo...”, decreasing in volume, duets; a “water-bottle”

Habitat. Dense vegetation or underbrush in forest, primary forest, recent clearings, second growth, eucalyptus woodlands, littoral forest, palms, mangroves, marshy reedbeds and grass, gardens. Sea-level to 1800 m.

Food and Feeding. Invertebrates, large insects (beetles, grasshoppers, caterpillars), spiders, lizards, rats, chicks and eggs. Feeds on ground, in thick scrub, chases grasshoppers and lizards in a tactic of "flush and rush"; rips bark from trees to get at lizards concealed behind; often feeds in pairs, one bird defending against theft of food by Crested Drongos (*Dicrurus forficatus*).

Breeding. Adults in breeding plumage Jul-Sept; nesting records Sept-Mar. Nest a large domed sphere, woven from dry grass, 1-4 m above ground in dense bush. Eggs 2-3 (Madagascar), 2 (Aldabra), smooth, white; 33 x 26 mm; highly variable in size and shape. Male attends nest. Older nestling, when feathered, has short pale shaft streaks.

Movements. Resident.

Status and Conservation. Not globally threatened. Widespread and fairly common in Madagascar, except on the denuded central plateau; estimated population of several hundred birds in Aldabra Is, where rather tame. Now extinct on Assumption I, a consequence of the mining of bird guano and the consequent destruction of soil and vegetation.

Bibliography. Bangs (1918), Benson (1967, 1981), Benson & Penny (1971), Benson *et al.* (1976-1977), Dee (1986), Delacour (1930, 1932a, 1932c), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Frith (1975), Kaudern (1922), Langrand (1990), Lippens & Wille (1976), Milon *et al.* (1973), Parkes (1957a), Pidgeon & O'Connor (1985), Pringle (1985), Prys-Jones & Diamond (1984), Rand (1936), Salvan (1972b), Snow (1978), van Someren (1947), Steinbacher (1972), Stoddart (1984), Werding (1972), Wilmé *et al.* (1997), Woodell (1976a, 1976b), Young, G. (1995).

96. African Black Coucal

Centropus grillii

French: Coucal noir

German: Grillkuckuck

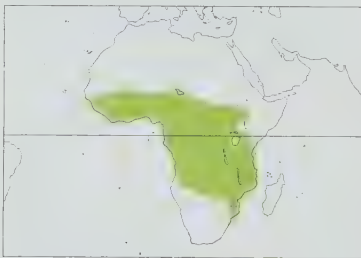

Spanish: Cucal Negro

Other common names: Black/Black-chested Coucal

Taxonomy. *Centropus Grillii* Hartlaub, 1861, Gabon.

Sometimes regarded as conspecific with *C. toulou*, but voices of the two differ; has also been considered possibly conspecific with *C. bengalensis*, but their ranges are highly disjunct and, again, vocalizations apparently differ. Monotypic.

Distribution. Senegal, Gambia and Ivory Coast through N Cameroon and Gabon to Ethiopia and Kenya, and S through S & E Zaire to Angola, Zambia, Malawi, N Zimbabwe, Mozambique and NE South Africa (NE Natal).

Descriptive notes. Male 30 cm, 100 g; female 34 cm, 151 g. Adult black with rufous wings, tail glossy black, iris dark brown, bill black, feet black. Non-breeding plumage dark brown above, barred rufous, streaked tawny and black from forehead to scapulars, buff below, bill brown above, pale blue-grey below, feet blackish. Female larger. Subadult, both plumages, wings and tail partly barred. Juvenile similar to non-breeding adult, but fully barred above, on tail and on belly, rump and uppertail-coverts black with narrow buff bars, iris pale grey, bill dark brown above, pale horn below, feet blue grey. **VOICE.** A double note repeated at 2-sec intervals, "kuk kuk"

or "ko-kop", also "hoo - hoo" at 1-sec intervals; song a descending "water-bottle" series of hoots, higher-pitched than in other coucals and not rising at end; alarm a clucking "tuk tuk".

Habitat. Tall rank grass and reedbeds, grassland near freshwater swamps, especially in wide grassy river valleys and marshes, and in seasonally flooded grasslands; not present in estuarine or tidal marshes.

Food and Feeding. Insects, especially grasshoppers, also beetles; spiders, mantids, small reptiles, seeds.

Breeding. Breeds during rains when grass is high, Apr-Jul in coastal Ghana, Jul-Aug in N Ghana and N Nigeria, Dec-Feb in N Tanzania (Serengeti, Mkomazi), Dec-Mar in Zimbabwe, Jan-May in Malawi. Female may be polyandrous (1 female observed with 3 males, each male tended a nest). Male feeds the female at copulation. Nest, built by male, an oval ball of dry grass and sedge, lined with leaves, concealed in grass or sedge 20-40 cm above ground. Eggs 3-6, white, laid at irregular intervals up to 9 days; 31 x 24 mm. Male incubates, and provides all the care of the young. Incubation from first egg; hatchling black, with long white hair-like down above, bill black with white egg tooth; fledges at 18-20 days, flies at 28 days. Female may lay several clutches in a season.

Movements. Resident in areas with permanent fresh water; other populations migrate into low-rainfall grasslands in rainy season. Uncommon sporadic and seasonal migrant in summer in S Africa in Kruger National Park and NE Natal. Seasonal with the rains in Aug-Oct in Middle River region in Gambia and at Prufu Swamp in Upper River region, and occurs in both wet and dry seasons on upper R Niger in Mali. Seasonal migrant in Ghana, where occurs in S May-Aug and in wetlands in N in the wet season Jul-Sept, though considered resident at Mole National Park; and in Togo, where present in the more humid S in dry season (Nov-Jul), and in N only in wet season (Jul-Aug), when in breeding plumage; no evidence of migration in Sierra Leone. Resident in S Nigeria; seasonal Apr-Oct during the rains in N Nigeria, and in the dry months Jan-Feb in Gabon.

Status and Conservation. Not globally threatened. Patchily distributed and generally scarce over its entire range, but can be common in suitable habitat locally, e.g. not uncommon in suitable habitat virtually throughout Sierra Leone. Seasonal disappearance of waters after rains and during the dry season is an important factor in its local population status.

Bibliography. Andersson (1995), Bannerman (1933, 1953), Benson & Benson (1977), Benson *et al.* (1971), Britton (1980a), Brooke (1984a), Brosset & Erard (1986), Cave & Macdonald (1955), Chapin (1939), Cheke & Walsh (1996), Clancey (1985), Dowsett & Dowsett-Lemaire (1980, 1993), Dowsett & Forbes-Watson (1993), Elgood, Fry & Dowsett (1973), Elgood, Heigham *et al.* (1994), Evans & Balmford (1992), Fry *et al.* (1988), Ginn *et al.* (1989), Giraudoux *et al.* (1988), Gore (1990), Greig-Smith (1976), Grimes (1987), Holman (1947), Irwin (1962), Lamiarche (1980), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Praed & Grant (1957, 1962, 1970), Maclean (1993), Nikolaus (1987), Parkes (1957a), Penny (1994), Pinto (1983), Rand *et al.* (1959), Rowan (1983), Rutgers & Norris (1972), Short *et al.* (1990), Snow (1978), Symmes (1960), Vernon (1971a, 1975), Vincent (1946), Wachter *et al.* (1997), Zimmerman *et al.* (1996).

97. Lesser Coucal

Centropus bengalensis

French: Coucal rufin

German: Bengalenkuckuck

Spanish: Cucal Bengali

Other common names: Small Coucal

Taxonomy. *Cuculus bengalensis* J. F. Gmelin, 1788, Bengal.

Has been considered possibly conspecific with *C. grillii*, but the ranges of the two forms are highly disjunct and their vocalizations appear to differ; also lumped with *C. toulou* in past. Five subspecies recognized.

Subspecies and Distribution.

C. b. bengalensis (J. F. Gmelin, 1788) - India and Nepal through Bangladesh, Myanmar and Thailand to Indochina.

C. b. lignator Swinhoe, 1861 - S & SE China, Hainan and Taiwan.

C. b. javanensis (Dumont, 1818) - Malay Peninsula through Sumatra, Riau and Lingga archipelago, Bangka and Belitung to Java, Bali, Borneo and Philippines.

C. b. sarasinorum Stresemann, 1912 - Sulawesi and Lesser Sundas.

C. b. medius Bonaparte, 1850 - Moluccas.

Descriptive notes. Male 31 cm (India), 34 cm and 88 g (Philippines); female 34 cm (India), 38 cm and 152 g (Philippines). Adult black above and below, often with pale streaking, wings pale rufous brown, tail glossy black narrowly tipped whitish, iris red to brown, bill black, legs black. Non-breeding plumage barred brown above, rufous-white with dusky bars below. Female larger. Juvenile dark brown above, all barred light rufous, streaked rufous on head and back, shaft streaks buffy-white, whitish buff below with paler shaft streaks, belly barred, undertail buff-barred black, iris brown. Races differ mostly in size; *sarasinorum* larger and darker than *bengalensis*, *medius* larger still. **VOICE.** In India, double series of notes, "whoot, whoot", repeated, then series of "kurook, kurook, kurook", increasing in tempo and descending in pitch. In Greater Sundas, deep hollow "hoop" notes, accelerating and descending, more rapid than in *C. sinensis*. In Java, 3-4 hollow notes breaking into staccato, "boob, boob, boob, kok-ok-oo, kok-ok-oo, kok-ok-oo", also 4 or 5 "whoop" notes that increase in tempo and fall in pitch. In Sulawesi, series of hollow "booh-booh..." breaking into a tinkling cadence.

Habitat. Tall grass, reedbeds, swamps and marshlands, bamboo thickets, second-growth forest, open-country scrub and cultivation. Generally in more open habitats than those preferred by *C. sinensis*. Lowland floodplains and lower valleys, to 1800 m.

Food and Feeding. Insects, including grasshoppers (Acrididae), locusts, crickets, mantids, beetles, Hemiptera, hairy caterpillars, also spiders, lizards (*Calotes*); fruit. Forages mostly on ground.

Breeding. Breeds in India after onset of rains in Jun, nests May-Sept; in Myanmar nests in the rains, in Malay Peninsula nests Dec-Jul, in Philippines in Jul. Nest, built by both sexes, domed and oval-shaped, with lateral entrance hole, of twigs, grass and leaves, lined with green leaves, near ground in dense vegetation. Eggs 2-4, chalky white; 28 x 24 mm (India), 30 x 24 mm (Java). Both sexes incubate and tend the young.

Movements. Resident. Perhaps only a summer visitor locally, e.g. in Nepal.

Status and Conservation. Not globally threatened. A common resident of open country, if somewhat local in some areas. Rapidly colonizes new habitat where forests are cleared, appearing up to 8 km from nearest suitable habitat within 3-5 years. On Krakatau, after the eruption and devastation of all animal life in 1883, this species colonized the island by 1908, after a flight of at least 15 km over open water. The larger potential competitor *C. sinensis* was heard once on Krakatau (on Sertung), in 1919, by which time present species had already established itself in open country.

Bibliography. 98. Green-billed Coucal

Centropus chlororhynchus

French: Coucal de Ceylan

German: Ceylonkuckuck

Spanish: Cucal de Ceilán

Other common names: Sri Lanka Green-billed/Ceylon Coucal

Taxonomy. *Centropus chlororhynchus* Blyth, 1849, Sri Lanka.

Monotypic.

Distribution. Sri Lanka.

Descriptive notes. 43-46 cm. Adult dull black on head, body and tail, neck and tail glossed purple, wings chestnut (darker than in sympatric *C. sinensis*), wing-linings black, iris red to reddish brown; bill ivory to pale green, feet black. Female larger. Juvenile as adult, but iris grey, bill greenish with dark grey base and culmen, feet dusky flesh colour. **VOICE.** Resonant deep "hoop-poop-poop", the last note lower in pitch; also a short 2-syllable "hu, hu", and a single-note "chewkk".

Habitat. Humid high evergreen forest with dense undergrowth, especially bamboo and rattan cane rushes in disturbed areas; occurs

in wet-zone forests W, SW & S of the C mountain massif. Low country to 800 m.

Food and Feeding. Omnivorous; takes termites. Feeds on ground and in trees and creepers.

Breeding. Breeds mainly May-Jul. Nest globe-shaped or domed, of twigs, roots and grass, lined with green leaves, built near ground. Eggs 2-3, chalky white; 35 x 27 mm.

Movements. Resident.

Status and Conservation. **ENDANGERED.** A rare, local and declining species, endangered by the continued loss of its forest habitat to agriculture. Its total population is estimated at no more than a few hundred pairs, and it appears to be most secure on the lower edge of Peak Wilderness Sanctuary in Sinharaja National Heritage Wilderness Area, Ratnapura District.

Bibliography. Ali & Ripley (1981), Collar & Andrew (1988), Collar *et al.* (1994), Henry (1971), Hoffmann (1984, 1989a, 1989b), Kotagama & Fernando (1994), Legge (1880), Phillips (1978), Ripley (1982), Wheatley (1996), Wijesinghe (1994).

99. Black-throated Coucal

Centropus leucogaster

French: Coucal à ventre blanc **German:** Weißbauchkuckuck **Spanish:** Cucal Ventri blanco
Other common names: Great Coucal(!)

Taxonomy. *Polophilus leucogaster* Leach, 1814, New Holland; error = Ghana. Range complementary to that of *C. anelli*, suggesting that the two may be allopecies. Race *neumanni* of Zaire has been considered to be more closely related to *C. anelli*, and perhaps even a distinct species, based mainly on size; size overlap occurs, but evidence unclear as sexes of specimens were not indicated. Three subspecies recognized.

Subspecies and Distribution.

C. l. leucogaster (Leach, 1814) - S Senegal and Guinea-Bissau E to SE Nigeria.

C. l. efulensis Sharpe, 1904 - SW Cameroon and Gabon.

C. l. neumanni Alexander, 1908 - NE Zaire.

Descriptive notes. 46-58 cm; male 293 g, female 336 g. One of largest of African coucals. Adult black above and from head to breast; back barred buff, tail glossed blue, wings rufous-chestnut darker at tips; belly white with creamy wash on flanks; iris red, bill black, feet black to blue-grey. Juvenile like adult, but lacks gloss on head and breast, head, throat and breast with short buff shaft streaks, wings barred brown, belly buffy, tail more barred. Iris grey or reddish brown, lower mandible horn. Race *leucogaster* glossed violet-blue; *efulensis* with blackish inner secondaries; *neumanni* as *efulensis* but smaller. **Voice.** Song deep, bub-

bling, 10-20 notes slowing in tempo and falling in pitch, middle notes well spaced, final ones rising and speeding, in a "water-bottle" phrase; calls at night.

Habitat. Dense undergrowth in forest edge, forest remnants, secondary forest, thickets, dense grass, especially along streams and at margins of raphia swamps, etc.; more numerous in heavy gallery forest and thick second growth than in primary forest. Lowland forest zone.

Food and Feeding. Insects, including caterpillars, spiders, beetles, grasshoppers; also snails and frogs. Feeds on or near ground.

Breeding. Breeds Dec in Sierra Leone, Nov in Liberia, Aug in Ghana, Jun-Nov in Cameroon, Mar-Dec in Uelle region of N Zaire. Nest a large ball of leaves and grass, lined with green leaves, up to 30 cm above ground in bush, in forest or in long grass. Eggs 2, white, elliptical; 38 x 28 mm. Nestling with dense white hair-like down above.

Movements. Resident.

Status and Conservation. Not globally threatened. Fairly common in forests of lower Casamance in S Senegal; common in forest habitat in Nigeria, though rarely seen because of its skulking habits; in Sierra Leone, not uncommon in lowland forests and in suitable habitat in areas formerly covered by forest. Has been observed in Monts Mandingues in SW Mali; uncommon in Ghana, rare in Togo. **Bibliography.** Bannerman (1933, 1953), Chapin (1939), Cheke & Walsh (1996), Colston & Curry-Lindahl (1986), Demey & Fishpool (1994), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), Fry *et al.* (1988), Grimes (1987), Helsens (1996), Lamarche (1980), Lippens & Wille (1976), Louette (1981, 1986), Mackworth-Præd & Grant (1970), Morel & Morel (1990), Rutgers & Norris (1972), Serle (1957), Snow (1978), Thiollay (1985), White (1965).

100. Gabon Coucal

Centropus anelli

French: Coucal de Gabon **German:** Anellkuckuck **Spanish:** Cucal de Gabón

Taxonomy. *Centropus anelli* Sharpe, 1874, Danger River, Gabon. Range complementary to that of *C. leucogaster*, suggesting that the two may be allopecies. Form *C. leucogaster neumanni* of NE Zaire has been considered more closely related to present species, and may even be a distinct species. Monotypic.

Distribution. S Cameroon and Gabon to NW Angola and C Zaire.

Descriptive notes. 46-58 cm; male 210 g. Adult purplish-glossed black above and on head; lower back buff, barred black; tail blackish bronze, wings rufous with darker tips; below rich tawny; iris red, bill black, feet black. Female larger; iris reddish brown. Juvenile dark brown above, head with pale shaft streaks, forehead buff (not black), wing black-barred rufous, tail black, barred buff, underparts rufous-buff, finely barred black, centre of belly unbarred buffy; iris grey-brown, bill dark grey above, greenish grey below, feet slate. **Voice.** Song 9-12 descending loud, deep notes delivered with head lowered and throat puffed out; another call a melancholy bass "ouh ouh ouh ouh..."; pairs call in duet.

Habitat. Primary forests, undergrowth in swampy forests, second growth, old cultivations, grassy swamps.

Food and Feeding. Omnivorous; diet includes insects (grasshoppers, katydids, beetles), molluscs, frogs, small snakes, small birds. Feeds mainly on or near ground; scavenges around camps and villages.

Breeding. Breeding begins with rains or in little dry season in wettest forest region: lays Dec-Feb in NE Gabon, young in Nov in Uelle, Mar in Angola. No information on nest, eggs or young.

Movements. Resident.

Status and Conservation. Not globally threatened. Fairly common to common, but difficult to observe. Population density 3-5 pairs/100 ha in Gabon, where its territories are mutually exclusive with those of *C. monachus*, the most closely related species at the same locality.

Bibliography. Bannerman (1933, 1953), Brosset & Énard (1986), Chapin (1939), Christy & Clarke (1994), Dowsett (1989), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Green & Carroll (1991), Irwin (1985), Lippens & Wille (1976), Louette (1981, 1986), Mackworth-Præd & Grant (1962, 1970), Pinto (1983), Snow (1978).

101. Blue-headed Coucal

Centropus monachus

French: Coucal à nuque bleu **German:** Mönchskuckuck **Spanish:** Cucal Monje

Taxonomy. *Centropus monachus* Rüppell, 1837, Kulla, northern Ethiopia. Possible intermediates occur between present species and *C. cupreicaudus*, and their vocalizations are similar; on occasion treated as conspecific. Several additional races described appear invalid: form "heuglini" with a blue (not violet) head, found along large permanent swamps in Sudan, appears to represent an immature plumage of *fischeri*; a separate race, *occidentalis*, sometimes recognized for birds of Gabon, but probably indistinct from *fischeri*; birds from Shaba in SW Zaire, described as smaller race *verheyeni*, in fact overlap in size with *fischeri*. Two subspecies recognized.

Subspecies and Distribution.

C. m. fischeri Reichenow, 1887 - Ivory Coast and Ghana through S Nigeria, S Cameroon, Gabon, N Angola and Zaire to S Sudan, NW Tanzania and highlands of Ethiopia and W Kenya.

C. m. monachus Rüppell, 1837 - Ethiopia to C Kenya.

Descriptive notes. 45-52 cm; male 171 g, female 237 g. Adult blue-glossed black from forehead to upper back; lower back and wings reddish brown; rump, uppertail-coverts and tail unbarred black, tail with greenish or bronze gloss; whitish to pale buff below, darker on flanks; iris red, bill black, feet black. Female larger. Juvenile has crown and neck blackish with buff shaft streaks, wings barred blackish, tail (except central rectrices) barred, throat darker buff, belly pale buff. Race *fischeri* slightly smaller, back and wings slightly duller (more olive); juvenile darker above. **Voice.** Deep and resonant, "water-bottle" and "coo"

phrases slower and deeper than those of other coucals. Songs begin with 2 "coo" phrases, pairs often duet; also a barking note and a raucous cackle.

Habitat. Swamps, marshes, papyrus and river banks, forest edge, mesic savannas near water or forest, dense cover, secondary growth, edges of villages and along trails; occurs in wetter habitats than *C. senegalensis*. Lowlands to 2000 m and 2500 m in Kivu volcanos, and to 2000 m in Kenya, where within the 1000+ mm rainfall region.

Food and Feeding. A generalist carnivore, diet including insects (mainly grasshoppers and beetles), also snails, nesting birds, bird eggs, lizards, snakes, frogs, mice and rats. Skulks within cover; shy.

Breeding. Breeds Jun-Jul in Togo, Mar-Jun in Nigeria, Jan and Apr-Sept in Cameroon, Aug-Mar in NE Gabon, May-Nov in Uelle (N Zaire), Sept and Feb-Jun around L Victoria. Nest an oval mass of dry grass and sedge (or sticks and dry leaves), lined with green leaves, with side entrance, concealed in bushes or tall grass or a dense tree, placed c. 30 cm to 3 m above ground. Eggs 3, white, light gloss; 34.5 x 27 mm. Hatchling has black skin with long white down.

Movements. Resident.

Status and Conservation. Not globally threatened. Generally common within its range; common in village areas in NE Gabon, and very common around L Victoria and L Kyoga. Nominated *monachus* seems to be less numerous, at least in Kenya.

Bibliography. Bannerman (1933, 1953), Britton (1980a), Brosset & Énard (1986), Brown & Britton (1980), Cave & Macdonald (1955), Chapin (1939), Cheke & Walsh (1996), Christy & Clarke (1994), Dowsett & Forbes-Watson (1993), Elgood *et al.* (1994), van den Elzen & König (1983), Friedmann (1930a, 1966), Fry *et al.* (1988), Grimes (1987), Irwin (1985), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1986), Mackworth-Præd & Grant (1957, 1962, 1970), Millet-Horsin (1921), Nikolaus (1987), Pinto (1983), Ripley & Heinrich (1966a), Rutgers & Norris (1972), Short *et al.* (1990), Snow (1978), van Someren (1949), Traylor (1960), Zimmerman *et al.* (1996).

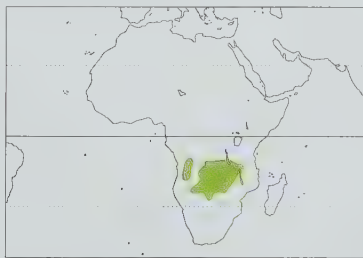

102. Coppery-tailed Coucal

Centropus cupreicaudus

French: Coucal des papyrus **German:** Kupferschwanzkuckuck **Spanish:** Cucal Colicobrizo

Taxonomy. *Centropus cupreicaudus* Reichenow, 1896, Okavangoland and south Angola. Has been treated as conspecific with the very similar *C. monachus*. Smaller and darker birds in N Malawi and S Tanzania have been described as separate race *songweensis*, but there is overlap in these traits with other populations. Monotypic.

Distribution. Angola through S Zaire and Zambia, by R Okavango and Caprivi Strip, E past Victoria Falls in Zimbabwe then N to Malawi and SW Tanzania.

Descriptive notes. 42-50 cm; male 272 g, female 299 g. Adult violet-glossed black from forehead to mantle; back and wings reddish brown; uppertail-coverts faintly barred, tail blackish brown with coppery gloss, underparts creamy white; iris red, deep bill black, feet black. Female larger. Juvenile less glossed, head with buff shaft streaks, tail barred, buff on breast. **Voice.** Series of 10-20 low-pitched, descending notes, in "water-bottle" pattern, similar to song of *C. monachus*, also low "cou...cou..." calls; pairs often duet.

Habitat. Swamps, marshes, river-bank vegetation, thickets, long grass. Lowlands to 1250 m.

Food and Feeding. Large insects, including grasshoppers, also snails, crabs, fish, frogs, snakes, lizards, small birds. Scavenges for dead fish; tears open bird nests to get at the young.

Breeding. Breeds Sept and Nov-Feb in Zambia, during rains. Nest a coarsely built dome of fresh grass and twigs, lined with leaves, with side entrance, low in reedbed. Eggs 2-4, white, little gloss; 38 x 26 mm. Hatchling has black skin with long white down.

Movements. Resident.

Status and Conservation. Not globally threatened. In general, a rather sparsely distributed bird; however, it is locally common, for instance in marshes along streams and rivers near upper R Zambezi.

Bibliography. Benson (1948), Benson & Benson (1977), Benson & Pitman (1964), Benson *et al.* (1971), Britton (1980a), Clancey (1985), Dowsett & Forbes-Watson (1993), Fry *et al.* (1988), Ginn *et al.* (1989), Irwin (1985), Lippens & Wille (1976), Louette (1986), Mackworth-Praed & Grant (1962, 1970), Maclean (1993), Penry (1994), Pinto (1983), Rowan (1983), Short *et al.* (1990), Snow (1978), Traylor (1960).

103. Senegal Coucal

Centropus senegalensis

French: Coucal du Sénégal **German:** Spornkuckuck **Spanish:** Cucal Senegalés
Other common names: Rufous-bellied Coucal ("epomidis")

Taxonomy. *Cuculus senegalensis* Linnaeus, 1766. Senegal.

Darker rufous form "epomidis" of coastal Nigeria and also Ghana has sometimes been treated as a valid race, or even as a separate species, but interbreeds freely with white-bellied form of nominate *senegalensis*. Three subspecies recognized.

Subspecies and Distribution.

C. s. aegyptius (J. F. Gmelin, 1788) - Egypt, from R Nile S to El Minya.

C. s. senegalensis Linnaeus, 1766 - Senegal and Gambia E to Uganda, W Kenya, Eritrea and Somalia, and S to NW Angola, SC Zaire and L Victoria.

C. s. flecki Reichenow, 1893 - E Angola, NE Namibia and N Botswana E through S Zaire (Shaba), Zambia and Malawi to Zimbabwe and SW Tanzania.

Descriptive notes. 36-42 cm; male 169 g, female 171 g. Black glossed green above, from forehead to mantle; back and wings rusty-brown, rump unbarred black, tail blackish with green gloss; white below; iris red, bill black. Female slightly larger. Also occurs as dark rufous morph "epomidis" with chin, throat and breast dark brown to black, belly, flanks and undertail-coverts rufous. May have subadult plumage, lacking gloss on head and with black tail. Juvenile barred brown and blackish above, crown brown or grey, wings barred rusty and dark brown, primaries unbarred but dark at tips, tail blackish with faint buff barring at tip.

underparts buffy, barred blackish on flanks. Race *flecki* has blue gloss on head; *aegyptius* larger, sootier, less rufous above. **Voice.** Deep tooting notes, falling in pitch then rising at end, in "water-bottle" call like that of other coucals; pairs often duet; also a series of deep "coo" notes, a short hoot, and sharp "guk, guk" alarm call.

Habitat. Coarse grass, thickets in woodland, edge of reedbeds, dense riverine bush, scrub, sugarcane plantations, gardens, palm groves; less associated with wet areas than other African coucals. In SW Tanzania (near Mbeya), lives along borders of dry-forest belt and flies into crowns of tall trees, whereas *C. superciliosus* lives in scattered dense low scrub and cane on flats and on the shores of small rivers and occasionally visits low acacias.

Food and Feeding. Insects (grasshoppers, caterpillars, termites, beetles, bugs), frogs, small rodents, reptiles, birds, bird eggs and nestlings, snails. Forages mainly on ground, moving by slow stalking walk, changing to hop and run; feeds on escaping insects by edge of grass fires.

Breeding. Breeds during rains, while grass is pliant and high enough to provide nest material and cover: Mar-Aug in Egypt, May-Oct in N Senegal, Jul-Nov in Gambia, Mar-Aug in Nigeria, Apr-Aug in Ethiopia, Nov-May in Malawi; Sept-May in Sierra Leone, chiefly before and after main rains. Nest a ball of coarse dry grass, lined with green leaves, to 4 m above ground in bush. Eggs 2-5, white; 34 x 26 mm; incubation 18-19 days. Hatchling has skin black above, dark pink below, with long white hair-like down, gape pink, tongue red; cared for by both sexes, fledging 18-20 days, before capable of flight.

Movements. Resident in most of its range; locally migratory in more arid areas, as in N Mali and C Sudan (W Kordofan), where a wet-season visitor.

Status and Conservation. Not globally threatened. Common in much of its sizeable range, e.g. abundant throughout Sierra Leone except in high forest. Has expanded its range from beginning of 20th century in Egypt, where formerly more restricted to El Faiyum region, but now quite common in Cairo and Rosetta Nile, and more recently also in the Nile Delta and lower valley.

Bibliography. Anon. (1985a), Ash & Miskell (1983), Bannerman (1933, 1953), Benson & Benson (1977), Benson *et al.* (1971), Britton (1980a), Brosset & Éard (1986), Brotherton (1965), Cave & Macdonald (1955), Chapin (1939), Cheke & Walsh (1996), Colston & Curry-Lindahl (1986), Cramp (1985), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Elgood (1955, 1973), Elgood *et al.* (1994), Échécopar & Hùe (1964), Fry *et al.* (1988), Ginn *et al.* (1989), Giraudeau *et al.* (1988), Goodman *et al.* (1989), Gore (1990), Granvik (1923), Greaves (1937), Greig-Smith (1977), Grimes (1987), Irwin (1985), Jensen & Kirkeby (1980), Lamarche (1980), Lewis & Pomeroy (1989), Lippens & Wille (1976), Lorber (1984a), Louette (1986), Mackworth-Praed & Grant (1957, 1962, 1970), MacLaren (1950), Maclean (1993), Marquard & Bryan (1983), Moynihan (1978), Nikolaus (1987), Penry (1994), Pinto (1983), Ripley & Heinrich (1966b), Rowan (1983), Rutgers & Norris (1972), Serle (1950a), Short *et al.* (1990), Snow (1978), Steyn (1972), Zimmerman *et al.* (1996).

104. White-browed Coucal

Centropus superciliosus

French: Coucal à sourcils blancs **German:** Weißbrauenkuckuck **Spanish:** Cucal Cejiblanco
Other common names: Lark-heeled Cuckoo; Burchell's Coucal (*burchelli*)

Taxonomy. *Centropus superciliosus* Hemprich and Ehrenberg, 1833, Arabia and Ethiopia.

The form *burchelli* might be recognized as a full species, although intermediates, apparent hybrids between forms with a supercilium and forms without, are known in Zimbabwe, Zambia, Mozambique and N Malawi. The difference in plumage suggests that adults of N forms have retained a juvenile-like plumage (with white supercilium and brown crown and hindneck), while adults of S form *burchelli* have a glossy black head and neck derived from an additional terminal plumage following the streaked plumage in which some birds breed. Birds from E Zimbabwe and Mozambique to E Tanzania, named as race *fasciopygialis*, are probably a variant of *burchelli*. Four subspecies recognized.

Subspecies and Distribution.

C. s. sokotrae C. H. B. Grant, 1915 - Socotra and SW Arabia (Tihama).

C. s. superciliosus Hemprich & Ehrenberg, 1833 - E Sudan, Ethiopia and W Somalia through Kenya and NE Uganda to NE Tanzania.

C. s. loandae C. H. B. Grant, 1915 - Uganda, SW Kenya and Tanzania through SE Zaire, N Malawi and Zambia to Angola, Botswana and N Zimbabwe.

C. s. burchelli Swainson, 1838 - E Botswana through S & E Zimbabwe and S Malawi to Mozambique and E Tanzania, and S to South Africa.

Descriptive notes. 36-42 cm; male 160 g, female 180 g. Adult has head dark brownish with broad white supercilium, mantle blackish, streaked whitish, back rufous-brown, rump finely barred black and buff, long heavy tail green-glossed black, wings chestnut; whitish below, breast with creamy yellowish to whitish hackles; iris red, bill black, feet black or bluish grey. Female larger. Juvenile streaked buff and brown on head and neck, buff supercilium, wings and tail barred rufous and blackish, underparts buff; iris red by time tail grown. Race *loandae* larger, crown blackish, upperparts darker and more reddish chestnut,

juvenile paler; *sokotrae* slightly paler and greyer, but not very distinct from nominate; *burchelli* has crown to mantle black, unstreaked and without supercilium, juvenile more rufous (also an immature plumage stage with pale buff supercilium, brown crown, blackish neck with straw-coloured streaks). **Voice.** Song a series of 10-20 notes, descending in pitch and increasing in tempo, like water gurgling from a narrow-necked bottle; pairs perform overlapping duet of "water-bottle" calls, one starting as the other completes its call. Also song of deep "coo" notes, falling and then rising in pitch, voice not so low as *C. anselli*; alarm a hiss and a "chuck".

Habitat. Riverside, dense bush, moist vegetation, tall rank grass, marshes, thickets, shrubby once-cultivated weedfields. Mostly lowland, also montane areas to 2200 m in bracken briar, even to 2800 m, and arid country.

Food and Feeding. Insects (mainly grasshoppers, crickets and locusts, beetles), spiders, snails, crabs, lizards, snakes, frogs, mice, small birds, including nestlings and eggs. Spends much time skulking in grass, bushes and other cover; forages at grass fires.

Breeding. Breeds Mar-Jun (mainly Apr-May) in Ethiopia, all months but mainly in wet seasons in Kenya (Apr-Jul and Aug in Ngong area), Dec-Feb in Zambia, Oct-Mar in Malawi, Sept-Feb in S Africa, Aug-Jan in SW Cape. Pairs are monogamous and territorial. Male feeds female a large insect at copulation. Nest a large untidy dome with side entrance, of grass and twigs, lined with leaves, at 0-10 m in reeds or bush. Eggs 3-5 (3-6), white; 34.5 x 26 mm; laying interval 24-48 h, sometimes a few days; incubation 14-15 days, from first egg, mainly by male; hatching asynchronous on different days. Hatchling has black skin with long white hair-like down, "like a spiny hedgehog"; young fed by both sexes, hiss and emit foul-smelling black cloacal liquid when disturbed. Fledging 18-20 days (14 days if disturbed); older young stay near nest until all are ready to leave, young barely able to fly at this stage, creep about quietly until parents arrive with food.

Movements. Resident.

Status and Conservation. Not globally threatened. Common in much of its range, and the commonest coucal in E Africa. Density of 1 pair every 0.5 km in marshy habitat in Transvaal. Generally avoided for human food, but coucals are sometimes eaten, and an observation of a chimpanzee (*Pan troglodytes*) eating this coucal suggests that the birds are probably not noxious in taste.

Bibliography. Ash & Miskell (1983), Bannerman (1953), Benson & Benson (1977), Benson *et al.* (1971), Britton (1980a), Brooke *et al.* (1990), Brown & Britton (1980), Cave & Macdonald (1955), Chapin (1939), Christy & Clarke (1994), Clancey (1964b, 1989a), Dowsett & Dowsett-Lemaire (1993), Dowsett & Forbes-Watson (1993), Evans, M.I. (1994), Evans, M.I. & Balmford (1992), Forsyth (1983), Frere (1984), Friedmann (1930a), Fry *et al.* (1988), Ginn *et al.* (1989), Hockey *et al.* (1989), Irwin (1985), Jennings (1981a, 1995), Lawson (1962), Lewis & Pomeroy (1989), Lippens & Wille (1976), Louette (1986), Mackworth-Praed & Grant (1957, 1962, 1970), Maclean (1993), McGill (1992), Nikolaus (1987), Pakenham (1979), Penry (1994), Pinto (1983), Porter *et al.* (1996), Rowan (1983), Rutgers & Norris (1972), Shak (1983), Short *et al.* (1990), Snow (1978), van Someren (1956), Zimmerman *et al.* (1996).

Subfamily COCCYZINAE

Genus *COCCYZUS* Vieillot, 1816

105. Dwarf Cuckoo

Coccyzus pumilus

French: Coulicou nain

German: Zwergkuckuck

Spanish: Cuclillo Enano

Taxonomy. *Coccyzus pumilus* Strickland, 1852, Trinidad; error = Venezuela.Forms a superspecies with *C. cinereus*. Monotypic.**Distribution.** Colombia (mainly on E slopes of Andes) through upper Orinoco Valley to NE Venezuela; recorded once in N Brazil (Roraima).**Descriptive notes.** 21 cm; 36 g. Adult brownish grey above, tail short, brownish grey with subterminal band black, white tip; throat and breast rufous merging to buff on flanks, abdomen white or buff; eye-ring red, iris red, bill black. Juvenile browner above, throat pearly-grey, eye-ring yellow, iris olive-brown. VOICE. Calls "churr", grating "trrr trrr trrr..."; dawn song "kööa kööa".**Habitat.** Tropical deciduous forest, gallery forest, secondary forest; open woodland, pastures with scattered trees, dry lowland scrub. Sea-level to 1000 m, occasionally to 2600 m near Bogotá, Colombia.**Food and Feeding.** Insects, especially caterpillars and treehopper nymphs, taken from trees, shrubs and ground.**Breeding.** Pair may nest all year. Monogamous, some polyandry (female mated with two males, both males helped rear young). Courtship feeding observed at all stages of nesting cycle. Nest a flimsy platform of twigs and vines in canopy of short tree. Eggs 2-3, dull white; 25 x 20 mm; two females may lay in a nest; incubation from first egg, by both sexes. Nestlings cared for by both sexes, fledge in 12 days. Nest success 56%; predation accounts for most of the nest losses.**Movements.** Resident, marked birds remaining on territory all year in Colombia; appearance is seasonal with the rains in Venezuelan savanna.**Status and Conservation.** Not globally threatened. Fairly common, and apparently secure for present. Has recently expanded its range into humid and wet regions where forests have been cleared for pasture.**Bibliography.** Dunning (1982), Fjeldså & Krabbe (1990), Friedmann (1948b), Hilty & Brown (1986), Kirwan (1996), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Naranjo (1982), Olrog (1968), Phelps & Phelps (1958), Ralph (1975), Short (1975), Sick (1985, 1993), Stotz *et al.* (1996), Thomas (1978, 1979), Whittaker (1995), Williams, R. (1995).

106. Ash-coloured Cuckoo

Coccyzus cinereus

French: Coulicou cendré

German: Grauehlnkuckuck

Spanish: Cuclillo Ceniciento

Taxonomy. *Coccyzus cinereus* Vieillot, 1817, Paraguay.Forms a superspecies with *C. pumilus*. Monotypic.**Distribution.** N & E Bolivia, Paraguay, Uruguay and N Argentina; also locally in C & S Brazil (Mato Grosso, Mato Grosso do Sul, Goiás, Bahia).**Descriptive notes.** 25 cm; 45 g. Adult brownish grey above, tail brown, ungraduated; white below, throat and breast buffy-grey, abdomen tinged buff, wing-linings pale buff, rectrices with narrow white tips below; eye-ring red, iris red, bill black, feet grey. Juvenile washed rufous above, tail brown with fine black bars near tip, no white tip, throat and breast greyish white. VOICE. A sonorous "cow-w cow-w cow", like *C. americanus* but without clucking at end.**Habitat.** Occupies variety of habitats including scrubby woodland, chaco scrub, tropical deciduous forest, gallery forest, riverine forest.

est. Lowlands to 900 m.

Food and Feeding. Insects.**Breeding.** Nest a flat oval platform of sticks and leaves, lined with leaves, in bush or tree. Eggs 2-4, white; 25.5 x 19 mm. Nestling mouth with white papillae, 5 on palate and 2 pairs around pharynx.**Movements.** Unknown; suspected seasonal austral migrant, perhaps migratory in extreme S. Records from E Peru, and possibly also from Colombia, indicate possible migratory movements or perhaps vagrancy.**Status and Conservation.** Not globally threatened. Little known about overall status, but species is considered generally uncommon throughout its variety of habitats in the lower tropical zone. Research required.**Bibliography.** Belton (1984), Canevari *et al.* (1991), Contreras (1979a), Contreras *et al.* (1990), Hayes (1995), Klimaitis & Moschione (1987), Narosky & di Giacomo (1993), Nellar (1993), Olrog (1968, 1984), de la Peña(1988), Pinto (1964), Remsen & Traylor (1989), do Rosário (1996), Schönwetter (1967), Short (1975), Sick (1985, 1993), Stotz *et al.* (1996), Straube & Bornschein (1995), Wetmore (1926).

107. Black-billed Cuckoo

Coccyzus erythrophthalmus

French: Coulicou à bec noir German: Schwarzschnabelkuckuck Spanish: Cuclillo Piquinegro

Taxonomy. *Cuculus erythrophthalmus* Wilson, 1811, near Philadelphia, Pennsylvania.Emendation of scientific name to "*erythrophthalmus*" is unjustified. Monotypic.**Distribution.** SC & SE Canada to SC & SE USA. Winters in NW & WC South America.**Descriptive notes.** 30 cm; male 47 g, female 54 g, heavier at migration. Adult brownish olive above, primaries brown, white below, long tail grey with narrow white tips below; eye-ring red, iris dark brown, bill black, feet dark grey. Juvenile with upperwing-coverts edged whitish or buff, buff wash on throat, sometimes rufous inner web of flight-feathers with dark leading edge, eye-ring grey (becoming buff to yellow in autumn), bill black above, grey below. VOICE. Rhythmic "cucucu, cucucu, cucucu" call begins with c. 5 notes, each on a lower pitch, then continued on same pitch, calls often grouped in staccato 2s and 3s. Silent on winter grounds.**Habitat.** High-ground forest, open woodland, thickets, willow (*Salix*), alder (*Alnus*), aspen (*Populus*), vines. On migration, occurs from tropical evergreen forest to arid subtropical scrub. Generally found from lowlands up to 2000 m.**Food and Feeding.** Insects, mainly caterpillars, also saw-flies, grasshoppers, crickets, beetles, spiders, phalangids; rarely frogs, small fish, eggs of other birds; berries especially in autumn. Feeds mainly in trees, and often on ground. Forages in tree foliage, cocks head, waits until insect moves, then grabs it. In winter joins mixed-species feeding flocks.**Breeding.** Breeds May-Sept; in Maryland May-Jul, in Oklahoma May-Jun. Courtship feeding occurs. Nest a shallow cup of sticks. Occasionally lays in nests of other individuals, also of *C. americanus* and other bird species. Eggs 2-5, light blue (darker than *C. americanus* eggs); 27 x 21 mm; incubation 10-11 days, from first egg, by both sexes, hatching asynchronous. Nestling has blackish skin with white sheathed down, mouth-lining reddish, ring of 5 white papillae on palate, 2 pairs elongate white papillae around pharynx, white papilla on tongue, feet blue; cared for by both parents, grow to 26 g at 6 days, fledging 8-14 days (first may fledge before last egg hatched in large clutches), fly at 21-24 days. Long nest attendance by adults, to 90 minutes.**Movements.** Migratory, moving at night through Mexico and Central America as late as Dec. Spring migration records at TV towers, where nocturnal migrants are killed, in Florida, Apr-May; autumn migrants late Aug to late Oct. Winters in W South America from Venezuela, Colombia, Ecuador and N Peru to Bolivia, from lowlands to 2800 m near Quito, Ecuador; accidental in N Argentina, Paraguay and Trinidad. Also transatlantic vagrant in autumn to W Europe.**Status and Conservation.** Not globally threatened. Breeding densities vary considerably across years, in apparent response to caterpillar outbreaks. Populations considered stable overall, and continent-wide numbers show no significant changes in period 1966-1993, with regional trends averaging insignificant annual variations of 1-1 % in W, 0-5 % in C, and 0-9 % in E.**Bibliography.** Agro (1994), Bent (1940), Berger (1952, 1954), Binford (1989), Canevari *et al.* (1991), Cramp (1985), Cyr (1995b), DeGraaf & Rappole (1995), Dod (1981), Dunning (1987), Fischer (1979), Fitzgerald (1995), Fjeldså & Krabbe (1990), Forbush (1927), Grocki & Johnston (1974), Harrison (1978), Herrick (1910), Hilty & Brown (1986), Howell & Webb (1995a), Johnsgard (1979), Kaufman (1996), Monroe (1968), Nolan (1975), Nolan & Thompson (1975), Parkes (1984), de la Peña (1988), Peterjohn *et al.* (1995), Peterson (1980), Price *et al.* (1995), Ridgely & Gwynne (1989), Roberts (1936), Robinson *et al.* (1995), Sealy (1978, 1985), Slud (1964), Spencer (1943), Stevenson & Anderson (1994), Stewart & Robbins (1958), Stiles & Skutch (1989), Stokes & Stokes (1996), Stotz *et al.* (1996), Sutton (1982), Terborgh *et al.* (1984), Thomas (1995), Trautman (1940), Wetmore (1968), Witter & Kulman (1972).

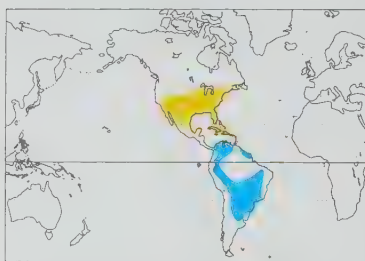

108. Yellow-billed Cuckoo

Coccyzus americanus

French: Coulicou à bec jaune German: Gelbschnabelkuckuck Spanish: Cuclillo Piquigualdo

Taxonomy. *Cuculus americanus* Linnaeus, 1758, South Carolina.Forms a superspecies with *C. euleri*. Birds in W North America average longer-winged and have been described as race *occidentalis*, but much overlap in size exists and most birds cannot be distinguished; "subspecies" records in non-breeding range are questionable. A claimed record of hybridization with *C. erythrophthalmus* refers to a juvenile *C. americanus*. Monotypic.**Distribution.** SE Canada and USA to Mexico (inland N Pacific slope, Baja California and Caribbean lowlands in Tamaulipas and Yucatán Peninsula) and N West Indies. Winters in South America.**Descriptive notes.** 30 cm; male 58 g, female 68 g, up to 110 g fat before migration, to 31 g after over-water migration. Adult brownish olive above, primaries rufous on inner webs, white below, long tail blackish with large white oval tips; eye-ring yellow to grey, iris dark brown, bill black above, yellow below, feet grey. Juvenile rectrices narrow, whitish tail spots large but indistinct, eye-ring grey, bill black above and grey below. VOICE. Rapid throaty "ka-ka-ka-ka-ka-ka-kow-kow-kow-kowlip", first notes loud and guttural, later ones slower and lower-pitched towards end; also a shorter knocking call, "ka-ka-ka", and soft repeated "coo"; call a single "kowlip".**Habitat.** High-ground forest with clear dark understorey, open woodland, shrubby pastures, riparian woodland, cottonwoods, willows (*Salix*), mesquite, thickets, tangles, and swamps. On migration, occurs from tropical evergreen forest and deciduous forest to arid scrub. In winter in Neotropics, occurs in gallery forest, tropical deciduous forest, secondary forest, occupying mainly woodland, scrub and bushy savanna in the lowlands; common on passage to 2800 m in Andes in Colombia and Ecuador, and migrants to 4200 m in Venezuela.

On following pages: 109. Pearly-breasted Cuckoo (*Coccyzus euleri*); 110. Mangrove Cuckoo (*Coccyzus minor*); 111. Cocos Cuckoo (*Coccyzus ferrugineus*); 112. Dark-billed Cuckoo (*Coccyzus melacoryphus*); 113. Grey-capped Cuckoo (*Coccyzus lansbergi*); 114. Cuban Lizard-cuckoo (*Saurothera merlini*); 115. Puerto Rican Lizard-cuckoo (*Saurothera vieillotii*); 116. Hispaniolan Lizard-cuckoo (*Saurothera longirostris*); 117. Jamaican Lizard-cuckoo (*Saurothera vetula*); 118. Chestnut-bellied Cuckoo (*Hyetornis pluvialis*); 119. Rufous-breasted Cuckoo (*Hyetornis rufigularis*).

Food and Feeding. Diet includes insects, mainly caterpillars, but also grasshoppers, katydids, crickets, cicadas and beetles; small lizards, especially *Anolis* in Caribbean, occasionally frogs; species takes eggs from bird nests; berries and fruit in summer and autumn. Forages in tree foliage, canopy and subcanopy; perches motionless, cocks head and waits until insect moves, then hops to grab it. Wintering birds join mixed-species flocks.

Breeding. Breeds May–Sept in E North America; Apr–Aug in Florida, May–Jul in Maryland, May–Sept in Ohio, May–Aug in Oklahoma, Mar–Sept in Texas; breeds May–Jul in Puerto Rico. Nest a platform of sticks, lined or not, near ground level to 30 m up in tree. Present species and *C. erythrophthalmus* sometimes lay in each other's nests and in nests of other birds. Occasionally more than one female lays in a nest. Eggs 3–5 (2–3 in Florida and Hispaniola), light blue; 30 x 23 mm; incubation 11 days (one report of 14 days), from first egg, by both sexes, hatching often asynchronous. Nestling has blackish skin with dusky grey sheathed down, mouth-lining reddish, ring of 5 white papillae on palate, 2 pairs elongate white papillae around pharynx, white papilla on tongue, feet blue-green; cared for by both sexes, fledging 8–9 days (total 18–21 days from incubation to fledging).

Movements. Migratory, at night. Over-water flight in autumn of 2000–3000 km to West Indies, from where it moves further S, or 4000-km direct flight from breeding range to mainland of South America; also migrates overland, where records in Panama Sept–Nov and Apr, rare in S Florida in winter; seasonal in Greater Antilles, where not seen Dec–Feb. Northbound migrants appear in Florida through May and into Jun, and possible southbound migrants begin to appear in kills at TV towers by Jul. On non-breeding islands southbound migrants appear by early Sept; in Netherlands Antilles, main autumn passage mid Oct to early Nov. Winters in South America E of Andes, from Colombia and Venezuela to Brazil (Mato Grosso), Uruguay and N Argentina; rare in Central America, and in the Guianas occurs mainly during passage periods (Oct, Nov, April). Remains in spring as late as early Jun in Surinam. Transatlantic vagrant in autumn to Greenland, W Europe, Morocco, Azores.

Status and Conservation. Not globally threatened. Breeding densities vary regionally across years, in apparent response to caterpillar outbreaks. Common in North America from the Great Plains eastward, with centres of density in S Great Plains (Oklahoma, E Texas, Louisiana). Scarce in W; has disappeared from riverine woodlands in California, Arizona and S Oregon with the loss of riparian woodland habitat. Results of linear transects reveal that numbers throughout North America have declined significantly in recent years (31% in period 1966–1993, 12% in 1984–1993). Broadly sympatric with *C. minor* in Hispaniola, Puerto Rico and Jamaica, and present all year round; occasional on S Bahama Is, with no breeding records.

Bibliography. 109. Pearly-breasted Cuckoo

Coccyzus euleri

French: Coulicou d'Euler **German:** Perlbrustkuckuck **Spanish:** Cuclillo Ventriblanco

Taxonomy. *Coccyzus Euleri* Cabanis, 1873, Cantagallo, Rio de Janeiro, Brazil.

Forms a superspecies with *C. americanus*. Formerly known as *Coccyzus julieni* but this name officially suppressed. Monotypic.

Distribution. NE Colombia and the Guianas through Amazonia to E Brazil (Mato Grosso, Paraná, Rio de Janeiro, São Paulo) S to N Argentina (Misiones). Distribution patterns and movements unclear, but may only be winter visitor to E Colombia, Venezuela (R Orinoco) and the Guianas.

Descriptive notes. 28 cm; 61 g. Adult uniform earth-brown above, light pearly-grey below, centre of belly whitish, long tail blackish with white tips, no rufous on wing, inner webs of primaries white (brown in *C. americanus*); eye-ring grey to black, iris brown to black, bill black above, mostly yellow or orange below, feet grey to bluish grey. Juvenile has wings rufous. VOICE. Slow series of “kuouup” notes, 1/sec; also short rattle followed by 4–9 accented notes as in *C. americanus*, “tuctuctuctuctuct towlp, towlp, towlp towlp”.

Habitat. Tropical lowland evergreen forest, gallery forest, secondary forest; sandy wood-

land, scrub. Sea-level to 900 m.

Food and Feeding. Insects, mainly caterpillars.

Breeding. Very little known. Breeding record in Oct in Roraima (N Brazil). Nest undescribed. Eggs 2 (post-ovulatory follicles).

Movements. An austral migrant. Known to be present on breeding grounds during the austral summer, and in the Guianas and Venezuela during the austral winter; however, limits of breeding and non-breeding distributions have not been ascertained, patterns of movement are unclear, and paucity of records in N of range means that firm conclusions can not yet be made. Recorded once in Leeward Is (Sombbrero I).

Status and Conservation. Not globally threatened. Generally rare; only 3 records in Surinam, where it is thought to be a migrant, and uncommon in Brazil, where it breeds S of the Amazon. Distribution of species is poorly known, and confusion with *C. americanus* makes reported observations difficult to assess. Further research is required.

Bibliography. Banks (1988b), Banks & Bock (1991), Canevari *et al.* (1991), Contreras *et al.* (1990), Dubs (1992), Haverschmidt & Mees (1994), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Olog (1968), Partridge (1961), de la Peña (1988), Phelps & Phelps (1958), Remsen & T aylor (1989), Remsen *et al.* (1986), Sick (1985, 1993), Snyder (1966), Stotz *et al.* (1996), Straube & Bornschein (1995), Tostain *et al.* (1992), Tubbs (1992), Willis & Oniki (1990, 1991).

110. Mangrove Cuckoo

Coccyzus minor

French: Coulicou manioc **German:** Mangrovekuckuck **Spanish:** Cuclillo de Manglar
Other common names: Maynard's Cuckoo

Taxonomy. *Cuculus minor* J. F. Gmelin, 1788, Cayenne.

Forms a superspecies with *C. ferrugineus*, with which has been considered conspecific. Up to 13 races have been described, but these were all based on small samples; larger series now available show no constant differences in colour or size among island populations in West Indies, or between island and continental populations. Monotypic.

Distribution. Caribbean parts of Florida through Bahamas to Greater and Lesser Antilles, and S Mexico (Sinaloa and Tamaulipas to Yucatán and Oaxaca) through Central America to Colombia, then E to estuary of Amazon; Trinidad.

Descriptive notes. 34 cm; 64 g. Adult greyish brown above, crown greyish, broad black eye-line, flight-feathers brown, tail dark with white oval tips; polymorphic, with dark morph rich cinnamon below, and pale morph whitish to buff below; eye-ring inconspicuous grey to yellow, iris brown, bill black above, yellow or orange below, feet grey. Juvenile with wing-coverts and flight-feathers edged rufous, eye-line and tail spots indistinct, breast buffy-white, bill dark above and pale below. Variation in coloration of upperparts and intensity of buff below appears not to be strictly geographic. VOICE. Low, guttural “gawk gawk

gawk gawk gaawk gaawk”, also a single “whit!”.

Habitat. *Avicennia* mangroves, estuaries, thickets near water, secondary forest, dry scrub and lightly wooded tropical deciduous forest, mainly in understorey, also montane (280–500 m) rain forest in Lesser Antilles. Coastal, mainly lowlands near sea-level, occurs locally to 1100 m, and sometimes breeds in semi-arid habitat as high as 1300 m.

Food and Feeding. Insects, mainly caterpillars and grasshoppers (Acrididae), also crickets, mantids, stick insects, roaches, earwigs, cicadas, stink bugs, beetles, spiders; snails, lizards, fruit. Perches and scans vegetation, then pursues its prey by hops and runs.

Breeding. Breeds May–Jul in S Florida, Apr–May in Cayman Is, Mar–Oct in Puerto Rico, Jul in Hispaniola, Mar–Jul in Lesser Antilles (St Vincent, Grenadines), Jul in S Mexico (Oaxaca). Nest a flat platform of sticks and leaves, 2–3 m above water in mangroves or in fork of tree above ground. Eggs 2 (2–4), white to bluish; 31 x 23 mm. Both parents carry food.

Movements. Migratory in S Florida and Florida keys, though a few winter records, mainly in inland hardwood hammocks; arrives in late Mar and departs in late Sept. Observations seasonal from Jan to Sept in Hispaniola. Permanent resident in Pacific region of Oaxaca. Hurricanes may be responsible for some episodic movements, and the different appearance of samples of cuckoos taken in the same place in different years may reflect natural reintroductions and local extinctions of small founding populations.

Status and Conservation. Not globally threatened. Generally uncommon to fairly common throughout range. Rare to uncommon in Florida (mainly on Gulf coast and keys), where jeopardized by human development of mangrove habitat. Common in West Indies, especially Jamaica and Puerto Rico, but uncommon in Cuba, and not known on Barbados E of the main chain of Lesser Antilles. Common in Caribbean Mexico and Central America to Pacific slope of W Panama, and from the Guianas (breeding unknown in French Guiana and Surinam) to Trinidad, but only a few records are known from Venezuela and Colombia; uncommon in Oaxaca, S Mexico.

Bibliography. Anon. (1983), Banks & Hole (1991), Benito-Espinal & Hautcastel (1988), Bent (1940), Biaggi (1983), Binford (1989), Bradley (1985), Brudnell-Bruce (1975), Buden (1987), DeGraaf & Rappole (1995), Dod (1981), Faaborg (1985), Faaborg & Winters (1979), ffrench (1991), Griscom & Greenway (1941), Harrison (1978), Haverschmidt & Mees (1994), Hilty & Brown (1986), Howell & Webb (1995a), Hughes (1997b), Kaufman (1996), Keith (1997), Langridge (1990), McNair (1991), Meyer de Schauensee & Phelps (1978), Monroe (1968), Paynter (1955), Peterson (1980), Phelps & Phelps (1958), Price *et al.* (1995), Ridgely & Gwynne (1989), Ridgway (1916), Robertson (1978a), Rowley (1984), Selander & Gillier (1959), Sick (1985, 1993), Slud (1964), Snyder (1966), Stevenson & Anderson (1994), Stiles & Skutch (1989), Stokes & Stokes (1996), Stotz *et al.* (1996), Terborgh *et al.* (1978), Thurber *et al.* (1987), Tostain *et al.* (1992), Wallace *et al.* (1996), Wetmore (1916, 1968), Wetmore & Swales (1931).

111. Cocos Cuckoo

Coccyzus ferrugineus

French: Coulicou de Cocos **German:** Cocoskuckuck **Spanish:** Cuclillo de Isla del Coco

Taxonomy. *Coccyzus ferrugineus* Gould, 1843, Cocos Island.

Forms a superspecies with *C. minor*, with which has been considered conspecific. Monotypic.

Distribution. Cocos I, off Costa Rica.

Descriptive notes. 32 cm; 70 g. Adult greyish brown above, forehead and crown slate, narrow blackish facial mask, remiges rufous (brown in *C. minor*), tail broadly white-tipped, underparts uniform rich buff; eye-ring yellow, bill black above, yellow below with black tip. Juvenile with tail pattern indistinct. VOICE. Utters a deep, coughing “kcha”, repeated 5–8 times; also makes a resonant guttural “k’k’k’k’ru’ho”.

Habitat. Tropical lowland evergreen forest; *Hibiscus* thickets, tangles, hanging vines along streams, second-growth forest.

Food and Feeding. Insects, including large ones (sphingid caterpillars, cicadas), also lizards. Forages in dense vegetation; hops and runs in vegetation.

Collar *et al.* (1994), Slud (1967), Stiles & Skutch (1989), Stotz *et al.* (1996).

Breeding. Not described.

Movements. Resident.

Status and Conservation. **VULNERABLE.** Uncommon, and vulnerable owing to its small range. It is confined to the forests of Cocos I., which has a total area of just 47 km², and is the least common of the native landbirds of that island. This is a poorly known cuckoo, and it is possibly under-recorded in the interior forests of Cocos I. Threats to the species' survival are rats, cats and overgrazing by introduced deer, pigs and goats. Populations should be closely monitored.

Bibliography. Anon. (1983), Collar & Andrew (1988),

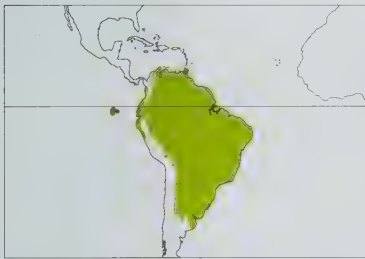

112. Dark-billed Cuckoo

Coccyzus melacoryphus

French: Coulicou de Vieillot **German:** Kleiner Mangrovekuckuck **Spanish:** Cuculillo Canela
Other common names: Azara's Cuckoo

Taxonomy. *Coccyzus melacoryphus* Vieillot, 1817, Paraguay. Monotypic.

Distribution. W Colombia, Ecuador and NW Peru; lowlands E of the Andes, from NE Colombia and Venezuela, Guianas and Brazil S to Uruguay and C Argentina, with one record N Chile; also Trinidad and Galapagos Is.

Descriptive notes. 27 cm; 50 g. Adult greyish brown above, buff below, crown and nape grey, black mask through eye and ear-coverts, narrow grey band down side of neck, tail long, bronzy above, blackish below, with broad white tips; eye-ring grey or olive-yellow, iris black, bill black, feet slate-grey. Juvenile duller, crown and nape brown, wings sometimes rufous, wing-coverts with indistinct buff tips, wing-linings buff (paler than in *C. americanus*), tail without distinct white tips. Voice. Song "cu-cu-cu-cu-kolp, kolp, kulop", of which last notes may be omitted; also utters a dry rattle, "dddddrr".

Habitat. Inhabits tropical deciduous forest, gallery forest, secondary forest, river-edge forest, shade trees of coffee plantations, tropical lowland evergreen forest; humid woodland edges, thickets and mangroves, drier ranchland shrubbery, forest openings, transitional forests with seasonal flooding, lake and river margins, thick viny growth, coastal plains. Mainly lowlands from sea-level to 1200 m, but to 1800 m in NW Argentina, to 2100-2400 m in Colombia, and to 2800 m in semi-arid montane valleys of Ecuador and E Andean slopes of Peru; high-altitude observations have been made up to 3600 m.

Food and Feeding. Diet known to include insects, mainly caterpillars, also grasshoppers, beetles and ants.

Breeding. Breeds Oct in Colombia, Oct-Dec in Argentina. Nest a flat platform of sticks, built in trees and bushes. Eggs 2-3, 3-4 (5) in Argentina, green to pale blue; 30 x 23 mm.

Movements. Partly migratory. Present throughout year W of Andes in Colombia; seasonal in non-breeding period (May-Sept) in the llanos of Venezuela, in Surinam and in Guianas, and in the breeding season (Oct-Dec) in S Brazil and Argentina. Accidental Falkland Is (Malvinas).

Status and Conservation. Not globally threatened. Generally reckoned to be fairly common throughout its expansive range, although no quantitative data available.

Bibliography. Belton (1984), Bennett (1937), Canevari *et al.* (1991), Contreras & Contreras (1990), Contreras *et al.* (1990), Dabbene (1926), Dunning (1987), Ervin (1989), Fjeldsá & Krabbe (1990), Friedmann (1927, 1948b), Harris (1973), Haverschmidt & Mees (1994), Herklots (1961), Hilty & Brown (1986), Johnson (1972), Klimaitis & Moschione (1987), Lévêque (1964), Meyer de Schauensee & Phelps (1978), Mitchell (1957), Nellar (1993), de la Peña (1988, 1996), Phelps & Phelps (1958), do Rosário (1996), Short (1975), Sick (1985, 1993), Sneath (1928), Snyder (1966), Stotz *et al.* (1996), Terborgh *et al.* (1984), Thomas (1978, 1979), Tostain *et al.* (1992), Wetmore (1926).

113. Grey-capped Cuckoo

Coccyzus lansbergi

French: Coulicou à tête grise **German:** Lansbergkuckuck **Spanish:** Cuculillo Cabecigrís

Taxonomy. *Coccyzus lansbergi* Bonaparte, 1850, Santa Fé de Bogotá, Colombia. Monotypic.

Distribution. N Colombia and N Venezuela. Migrates to SW Ecuador and W Peru.

Descriptive notes. 26 cm; 47 g. Adult rufous brown above with grey cap, dark rufous buff below, long black tail with white tips, central rectrices all dark; eye-ring dull yellowish grey, iris brown, bill black with grey or yellow basal spot below, feet blackish. No information available on juvenile plumage. Voice. Fast series of 6-8 hollow "cu" notes, "cucucucucucu-cu".

Habitat. Tropical deciduous forest, arid forest, bushy fields, gallery forest, in middle storey and canopy; low thickets and dense shrubs near water. Sea-level to 800 m, to 600 m in Colombia, occasionally to 1400 m in Venezuela.

Food and Feeding. Insects, mainly caterpillars.

Breeding. Nest a flat platform of twigs and lichens, 1-2 m above ground in horizontal branches. Eggs 2-3, greenish white; 26 x 20 mm.

Movements. Not well known. Wholly or partly migratory; seasonal in SW Ecuador; observed in Bosque Ampay in Apurímac, C Peru, suggesting an Andean crossing. A record from Bonaire in

Lesser Antilles may also indicate dispersal or seasonal movements, but otherwise no records in S Caribbean islands or West Indies.

Status and Conservation. Not globally threatened. Distribution is incompletely known, and species appears to be generally rare within limited known range. Further research required, primarily to define limits of range.

Bibliography. Anon. (1983), Bloch *et al.* (1991), Butler (1979), Dunning (1982, 1987), Fjeldsá & Krabbe (1990), Griscom & Greenway (1941), Hilty & Brown (1986), Koepcke (1970), Marchant (1960), Meyer de Schauensee (1982), Meyer de Schauensee & Phelps (1978), Parker *et al.* (1982), Phelps & Phelps (1958), Ridgely & Gwynne (1989), Schönwetter (1967), Stotz *et al.* (1996), Voous (1983).

Genus SAUROTHERA Vieillot, 1816

114. Cuban Lizard-cuckoo

Saurothera merlini

French: Tacco de Cuba **German:** Eidechsenkuckuck **Spanish:** Cuco-lagartero Cubano
Other common names: Great Lizard Cuckoo

Taxonomy. *Saurothera merlini* d'Orbigny, 1839, Cuba.

Population of Andros has sometimes been separated as race *andrina*. Four subspecies recognized.

Subspecies and Distribution.

S. m. bahamensis Bryant, 1864 - Bahama Is of Andros, New Providence and Eleuthera.

S. m. santamariae Garrido, 1971 - islands off NC Cuba.

S. m. merlini d'Orbigny, 1839 - Cuba.

S. m. decolor Bangs & Zappey, 1905 - I of Pines.

Descriptive notes. 54 cm; 154 g. Adult olive-brown above, primaries rufous, breast light grey, belly rufous, long tail grey with black subterminal band and broad white tips, central rectrices all grey; bare skin around eye red, iris grey to brown, bill long and straight, blackish above, paler below. Juvenile rectrices narrow, more pointed and without distinct terminal spots, iris brown. Race *decolor* greyish brown above; *santamariae* longer-billed; *bahamensis* smaller, grey above, belly washed buff, central rectrices with subterminal black band. Voice. A throaty "ka-ka-ka-ka-ka-kau-kau-ko-ko", also a guttural "tuc-wuh-h".

Habitat. Tropical lowland evergreen forest, tropical deciduous forest, secondary forest, pine forest; seen in woodland and thickets, vines and creepers, abandoned coffee plantations, overgrown pastures, and rough limestone hills. Lowlands to 1200 m.

Food and Feeding. Lizards, locusts. Forages in middle storey and canopy. No further information available.

Breeding. Nest a shallow saucer of twigs, in tree. Eggs 2-3, white; 40 x 30 mm.

Movements. Resident.

Status and Conservation. Not globally threatened. Rather limited range, but species is common to fairly common, widespread and rather tame. Used in traditional medicine for claimed effectiveness in convalescence and restoration of sexual powers.

Bibliography. Anon. (1983), Barbour (1943), Bond (1985), Brudenell-Bruce (1975), Garrido (1971), Garrido & García (1975), Miller (1894), Ridgway (1916), Schönwetter (1967), Stotz *et al.* (1996), Sulley & Sulley (1992), Todd & Worthington (1911), Vaurie (1957), Wallace *et al.* (1996), Wauer (1996).

115. Puerto Rican Lizard-cuckoo

Saurothera vieilloti

French: Tacco de Porto Rico **Spanish:** Cuco-lagartero Portorriqueño
German: Puerto-Rico-Kuckuck

Taxonomy. *Saurothera vieilloti* Bonaparte, 1850, Antilles.

Has been considered conspecific with *S. longirostris* and *S. vetula*, and these three form a superspecies. Monotypic.

Distribution. Puerto Rico.

Descriptive notes. 42 cm; 80 g. Adult washed rufous above, primaries same colour as back, tail long with broad white tips, throat white, breast grey, belly rufous; bare skin around eye red, white crescent below eye, iris brown, bill long and straight, black above, pale below. Juvenile brown above with rufous feather edges, chin and throat light grey, belly paler rufous than adult, tail narrower and paler with broad black bands, tips more pointed, bill dark above, pale below. Voice. As congeners, an emphatic "ka-ka-ka-ka..." gradually accelerating and becoming louder, also soft call "caw".

Habitat. Tropical deciduous forest, tropical lowland evergreen forest; woodland, coffee plantations, brush-covered limestone hills. Lowlands and in mountains to 800 m.

Food and Feeding. Small lizards, large spiders, large insects (stick insects). Forages in middle storey and canopy. Often lifts bits of loose bark off trees and dead pieces of cacti, in order to reveal prey beneath.

Breeding. Breeding records in Apr, May, Sept, Nov and Dec. Nest a loose platform of sticks and leaves. Eggs 2-3, pale blue with a thin white layer; 34 x 25 mm.

Movements. Resident.

Status and Conservation. Not globally threatened. Very limited range, within which species appears to be generally common to fairly common, but locally rare, in wooded areas.

Bibliography. Anon. (1983), Biaggi (1983), Bond (1985), Faaborg (1985), Faaborg & Winters (1979), Raffaele (1989), Schönwetter (1967), Stotz *et al.* (1996), Wauer (1996), Wunderle (1995).

116. Hispaniolan Lizard-cuckoo

Saurothera longirostris

French: Tacco d'Hispaniola **German:** Haitikuckuck **Spanish:** Cuco-lagartero de la Española

Taxonomy. *Cuculus longirostris* Hermann, 1783, Hispaniola.

Has been considered conspecific with *S. vieilloti* and *S. vetula*. Population of Saona I has sometimes been separated in race *saonae*. Two subspecies recognized.

Subspecies and Distribution.

S. l. longirostris (Hermann, 1783) - Hispaniola and Saona I.

S. l. petersi Richmond & Swales, 1924 - La Mahotiére and Gonâve I.

Sea-level to 2000 m.

Food and Feeding. Insects (especially grasshoppers, mantids, also caterpillars, cockroach, cicadas), small snakes and lizards. Forages in middle storey and canopy, moving with long strides through branches, also creeps and crawls through dense branches near ground; rests quietly for minutes; inquisitive and fearless.

Breeding. Breeding records in May (eggs), Jun (fledgling) and Dec (grown juvenile). Nest a flat platform of leaves, placed on stump of a tree. Eggs 2-3, pale blue with a thin white layer; 37 x 25 mm.

Movements. Resident.

Status and Conservation. Not globally threatened. Common to fairly common within rather restricted range. Rural people eat the flesh of this cuckoo in the traditional belief that it will promote appetite and cure indigestion.

Bibliography. Anon. (1983), Bond (1985), Dod (1981, 1987, 1992), Faaborg (1985), Kaempfer (1924), Latta & Wunderle (1996), Stotz *et al.* (1996), Wauer (1996), Wetmore & Swales (1931), Wunderle & Latta (1996).

117. Jamaican Lizard-cuckoo

Saurothera vetula

French: Tacco de la Jamaïque **German:** Jamaikakuckuck **Spanish:** Cuco-lagartero Jamaicano
Other common names: Old Woman Bird

Taxonomy. *Cuculus Vetula* Linnaeus, 1758, Jamaica.

Both *S. vieilloti* and *S. longirostris* have been considered races of present species. Monotypic.

Distribution. Jamaica.

Descriptive notes. 40 cm; 95 g. Adult greyish above, forehead to nape dark brown, wings with rufous patch formed by primaries, throat whitish, below rufous, paler on undertail-coverts; tail long, central rectrices grey with black subterminal band and broad white tip, others black with broad white tips; orbital skin red, iris brown, bill long, straight, black above, paler below. No information available on juvenile plumage. **VOICE.** Rapid, low "cak-cak-ka-ka-ka-k-k".

Habitat. Tropical lowland evergreen forests, possibly also tropical deciduous ones; wooded areas and semi-arid country with trees and

shrubs, in wet mountain areas and brush-covered limestone hills. Lowlands to 1200 m.

Food and Feeding. Lizards, caterpillars, locusts, nestling birds. Forages in middle storey and canopy.

Breeding. Courtship feeding and copulation observed in Oct. Nest a flat platform of twigs, lined with leaves, in a tangle of branches, twigs and bromeliads in a tree. Eggs pale blue; 32.5 x 24 mm.

Movements. Resident.

Status and Conservation. Not globally threatened. Widespread within limited range of Jamaica, but generally uncommon. Compared with its congeners, relatively little is known about this species, and further research is required to determine various aspects of its breeding.

Bibliography. Anon. (1983), Bond (1985), Cruz (1975), Curio (1970), Danforth (1928), Downer & Sutton (1990), Gosse (1847), Levy (1984), Schönwetter (1967), Stotz *et al.* (1996), Wauer (1996).

Genus *HYETORNIS* P. L. Sclater, 1862

118. Chestnut-bellied Cuckoo

Hyetornis pluvialis

French: Piaye de pluie **German:** Regenkuckuck **Spanish:** Cuco Picogordo de Jamaica
Other common names: Old Man Bird, Hunter

Taxonomy. *Cuculus pluvialis* J. F. Gmelin, 1788, Jamaica.

Sometimes included within genus *Piaya*. Monotypic.

Distribution. Jamaica.

Descriptive notes. 50 cm; 130 g. Adult large, dull brown above, face and breast light grey, throat paler, belly dark rufous, tail purple-glossed black with broad white tips; orbital skin black, iris red to brown, bill rather heavy, thick and decurved, blackish, feet dark grey. Juvenile with tail unglossed dark brown, but also showing the broad white tips that are present in the adult. **VOICE.** Hoarse "quak-quak-ak-ak-ak", slow, then accelerating towards end.

Habitat. Tropical lowland evergreen forest, secondary forest, in thickets in open areas, woodland; in wet mountain areas and brush-covered

limestone hills. Lowlands to 1500+ m.

Food and Feeding. Lizards, mice, insects, caterpillars, nestlings and eggs. Forages in middle storey and canopy of forest; runs along branches, glides on outstretched wings from tree to tree.

Breeding. Nest a shallow saucer of twigs, placed in tree. Eggs 2-4, white.

Movements. Resident. Moves to lower elevations in winter.

Status and Conservation. Not globally threatened. An uncommon and rather poorly known cuckoo with restricted range; further research and a proper survey of this species' population and status are needed.

Bibliography. Anon. (1983), Bond (1985), Cruz (1973), Danforth (1928), Downer & Sutton (1990), Faaborg (1985), Gosse (1847), Levy (1996), Stotz *et al.* (1996), Wauer (1996).

119. Rufous-breasted Cuckoo

Hyetornis ruficularis

French: Piaye cabrite **German:** Dominikanerkuckuck **Spanish:** Cuco Picogordo de la Española
Other common names: Bay-breasted Cuckoo

Taxonomy. *Coccyzus ruficularis* Hartlaub, 1852, mountain forests of Dominican Republic. Sometimes included within the genus *Piaya*. Monotypic.

Distribution. Hispaniola and Gonâve I.

Descriptive notes. 48 cm; 128 g. Adult grey above, chestnut on primaries, chin to breast dark chestnut, belly pale rufous, tail long with broad white tips; eyelids yellow, iris brown, decurved bill black with yellow lower mandible, feet grey. No information available on juvenile plumage. **VOICE.** Guttural crow-like call, "û-wack-û-wack-û-wack-"; also bleats like a lamb.

Habitat. Tropical deciduous forest in arid lowlands to mountain rain forest. Lowlands to 900+ m.

Food and Feeding. Insects, including grasshoppers, mantids, grubs and caterpillars, pentatomids and beetles; also lizards, mice. Forages in middle storey and canopy; leaps from branch to branch in trees.

Breeding. Virtually unknown. One bird in May had an egg in the oviduct, ready to be laid. Nests in trees, on a platform of sticks. Eggs 2, white.

Movements. Resident.

Status and Conservation. **VULNERABLE.** A shy species which remains in cover, this cuckoo is apparently rare to uncommon within its restricted range. It is considered vulnerable because of an evident decline in its numbers in 20th century. It occurs in four protected areas in W Dominican Republic, where it is rare; most recent records come from lower portions of Sierra de Bahoruco National Park, in the centre of the island, where good forest persists. It is at best exceedingly rare in Haiti, whence it may already have disappeared; there are no recent records from Gonâve I. A thorough survey of the species is needed throughout its range.

Bibliography. Anon. (1983), Bond (1928a, 1985), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory (1895), Danforth (1929), Dod (1981, 1987, 1992), Moltoni (1932), Schwartz & Klinikowski (1965), Stotz *et al.* (1996), Verrill & Verrill (1909), Wauer (1996), Wetmore & Swales (1931).

120

ssp. gracilis

ssp. minuta

126

Genus *PIAYA* Lesson, 1830

120. Squirrel Cuckoo

Piaya cayana

French: Piaye écreuil

German: Eichhornkuckuck

Spanish: Cuco-ardilla Común

Taxonomy. *Cuculus cayanus* Linnaeus, 1766, Cayenne.

The abruptness and rarity of intergradation between the forms *mexicana* and *thermophila* in Oaxaca, S Mexico, suggest that these forms may belong to distinct species, though a few intermediates are known. Fourteen subspecies recognized.

Subspecies and Distribution.

P. c. mexicana (Swainson, 1827) - Mexico, on Pacific slope and inland S to Isthmus of Tehuantepec.
P. c. thermophila P. L. Sclater, 1860 - E Mexico (E San Luis Potosí and S Tamaulipas S to Veracruz, Yucatán and Isthmus of Tehuantepec on Gulf coast S to near Tehuantepec City) through Central America to Panama and NW Colombia.

P. c. nigricrissa (Cabanis, 1862) - W Colombia (occurring E to slopes of C Andes), W Ecuador, NW & EC Peru.

P. c. mehleri Bonaparte, 1850 - NE Colombia E of Gulf of Urabá to Magdalena Valley and along W slope of E Andes, E in coastal Venezuela to Paria Peninsula.

P. c. mesura (Cabanis & Heine, 1863) - Colombia E of Andes, and E Ecuador.

P. c. circe Bonaparte, 1850 - Venezuela S of L Maracaibo.

P. c. cayana (Linnaeus, 1766) - E & S Venezuela through the Guianas and S to N bank of lower Amazon.

P. c. insulana Hellmayr, 1906 - Trinidad.

P. c. obscura Sneath, 1908 - C Brazil S of Amazon, from R Jurua E to R Tapajós and S to upper Gy-Paraná.

P. c. hellmayri Pinto, 1938 - Brazil S of Amazon, from Santarem to mouth of Amazon, and coast of N Maranhão.

P. c. pallescens (Cabanis & Heine, 1863) - E Brazil.

P. c. cabanisi J. A. Allen, 1893 - S Brazil, in C Mato Grosso and Goiás to N São Paulo.

P. c. macroura Gambel, 1849 - SE Brazil to Paraguay, NE Argentina and Uruguay.

P. c. mogenseni J. L. Peters, 1926 - S Bolivia to NW Argentina.

Descriptive notes. 46 cm; 98 g (Mexico and Central America). Race *mexicana* rich chestnut above, long graduated tail rufous above with black subterminal band and white tip; throat rufous, breast and abdomen grey, undertail-coverts black, undertail dark chestnut with broad white tips; bare skin around eye yellowish green (red E of Andes), iris red, feet light bluish grey. Juvenile similar, tail without black band, skin around eye grey, iris brown, bill grey-horn, feet grey. Race *thermophila* darker rufous, belly and undertail-coverts dark grey to black; *nigricrissa* darker still, belly and undertail-coverts blackish; *mehleri* more rufous, lighter throat and breast grading to light grey on belly, undertail blackish; *mesura* as *nigricrissa*, averages smaller (overlap); *circe* slightly more rufous than *mehleri*; *cayana* as *thermophila*, belly ashy-grey, undertail-coverts darker grey; *insulana* similar, but undertail-coverts black; *obscura* darker (less rufous); *hellmayri* more tan (less rufous); *pallescens* paler, more tan and less red or grey; *cabanisi* more rufous, rusty throat, pale below; *macroura* dark above, belly and undertail-coverts blackish, long purple tail; *mogenseni* lighter rufous above, dark grey (not blackish) below, rusty throat. VOICE. A 3-note dry rolling "hic-a-ro" or "geep-kareer", a "chick-kaw", a repeated "wheep-wheep-wheep...", a dry rattle or churr, and a sharp "kipi".

Habitat. Tropical lowland evergreen forest, tropical deciduous forest, old secondary forest, gallery forest, mangroves, flooded tropical evergreen forest; occurs in canopy in open forest, tangles of vine, coffee plantations, shrubbery, pastures with scattered trees, watercourses in dry regions, high-ground forest, transitional forest with seasonal inundations, also residential areas (Brazil), avoids dense lowland forests. Lowlands at sea-level to 2700 m.

Food and Feeding. Insects, mainly caterpillars (green or hairy), grasshoppers, stick insects, moths, beetles, ants. An arboreal gleaning insectivore in canopy and subcanopy, usually in pairs, or in mixed flocks, sometimes solitary; occasional at army-ant swarms. Hops along limbs or through vines in bounding leaps; leaps from branch to branch, runs along branch like a squirrel, glides across open spaces with bursts of shallow wingbeats. Forages by concealment in foliage, scans surfaces of leaves, then pounces; also catches flying ants with short fluttering flights, and capable of sustained flight.

Breeding. Breeds in Mexico in Jul (Jalisco), May (Oaxaca); in Costa Rica in both dry and wet seasons, Jan-Aug; in French Guiana Apr-Sept, in Surinam Mar-Jul and Sept. Adult feeds its mate. Nest a shallow platform of leaves, or sticks and green leaves, in thick shrubbery or in tree (resembles deciduous litter hanging in lianas of thick understory). Eggs 2-3, chalky white; 35 x 26 mm; incubation 18 days, by both parents, in spells of 6-8 hours each. Nestling (*mexicana*) has black skin covered with hair-like down, mouth-lining red (black in adults); cared for by both parents, fed large insects (c. 1 per hour); young leave nest before they can fly, by 8+ days. Nests repeatedly in a season.

Movements. Resident.

Status and Conservation. Not globally threatened. Generally common to very common throughout most of its extensive range, e.g. common in many parts of Guatemala, Costa Rica, Colombia, Ecuador, Brazil and Bolivia; density of 4 pairs/100 ha recorded in area of floodplain forest in Amazonian Peru.

Bibliography. Belton (1984), Binford (1989), Canevari *et al.* (1991), Chebez (1993), Contreras *et al.* (1990), Cory (1918), Fjeldså & Krabbe (1990), Friedmann (1948b), Griscom & Greenway (1941), Gyldenstolpe (1945), Haffer (1975), Haverschmidt & Mees (1994), Hellmayr (1929), Herklots (1961), Hilty & Brown (1986), Howell & Webb (1995a), Junge (1937b), Klimaitis & Moschione (1987), Meyer de Schauensee & Phelps (1978), Miller (1963),

Mitchell (1957), Monroe (1968), Naumburg (1930), de la Peña (1988), Phelps & Phelps (1958), Pinto (1938), Ridgely & Gwynne (1989), do Rosário (1996), Rowley (1984), Schaldach (1963), Schubart *et al.* (1965), Selander & Giller (1959), Short (1975), Sick (1985, 1993), Skutch (1966, 1983), Slud (1964), Snyder (1966), Stiles & Skutch (1989), Stotz *et al.* (1996), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Tostain *et al.* (1992), Waldrigues *et al.* (1983), Wetmore (1939, 1968), Willis & Eisenmann (1979), Zimmer (1930).

121. Black-bellied Cuckoo

Piaya melanogaster

French: Piaye à ventre noir

German: Schwarzbauchkuckuck

Spanish: Cuco-ardilla Ventrinegro

Taxonomy. *Cuculus melanogaster* Vieillot, 1817, Java; error = Cayenne.

Monotypic.

Distribution. SE Colombia, E Venezuela and the Guianas S to E Ecuador, E Peru, N Bolivia and Brazil (Amazonia S to Mato Grosso).

Descriptive notes. 38 cm; 102 g. Adult rufous-chestnut above with light grey cap, throat and breast orange-buff, becoming black on abdomen and undertail-coverts, tail rufous with subterminal black band and broad white tip; bare orbital skin pale blue, large yellow loreal spot, iris dark brown to red, bill red, feet lead-grey to black. Juvenile similar. VOICE. Song a loud "jjit, jjit-jjit-jjit"; scratchy descending "yaaaaa", also a dry rattle.

Habitat. Tropical lowland evergreen forest, absent from coastal region; also occurs in shrubby growth away from forest, and occasionally in savanna woodland. Lowlands to 800 m.

Food and Feeding. Insects, including grasshoppers, katydids, caterpillars, beetles and ants. Feeds in canopy.

Breeding. One record of young being fed in Jul, French Guiana. Nest undescribed. Eggs white; 30 x 23 mm.

Movements. Resident.

Status and Conservation. Not globally threatened. Generally uncommon and relatively little known. Despite occurrence in shrubby vegetation, species is reckoned to be sensitive to habitat disturbance.

Bibliography. Dunning (1987), Friedmann (1948b), Griscom & Greenway (1941), Haverschmidt & Mees (1994), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Naumburg (1930), Olog (1968), Parker & Remsen (1987), Phelps & Phelps (1958), Remsen & Traylor (1989), Schönwetter (1967), Schubart *et al.* (1965), Sick (1985, 1993), da Silva (1996), Snyder (1966), Stotz *et al.* (1996), Tostain *et al.* (1992).

122. Little Cuckoo

Piaya minuta

French: Petit Piaye

German: Rötelkuckuck

Spanish: Cuco-ardilla Menor

Taxonomy. *Coccyzus minutus* Vieillot, 1817, Cayenne.

Four subspecies recognized.

Subspecies and Distribution.

P. m. panamensis Todd, 1912 - E Panama and N Colombia W of Gulf of Urabá.

P. m. gracilis (Heine, 1863) - Colombia W of Andes, and W Ecuador.

P. m. minuta (Vieillot, 1817) - Colombia E of Andes, Venezuela and Guianas S to Amazonian Peru, SC Brazil (Goiás, Mato Grosso) and Bolivia; Trinidad.

P. m. chaparensis Cherrie, 1916 - N Bolivia.

Descriptive notes. 25 cm; 40 g. Adult chestnut above, throat and breast rufous-chestnut, belly dark buffy-grey, tail with white terminal spots; eye-ring red, iris red, bill greyish yellow with dusky tip, feet dull blue to greyish black. Juvenile grey-brown above, darker grey below, wings rufous or blackish, no white on tail, iris brown, bill dark to black, feet black. Race *gracilis* paler on throat and breast with particularly pale area around base of bill. VOICE. Harsh clucks, "tchek", like a tree frog; sharp "quienk", a nasal chattering "aannh anhh-anhy-anhh", a low whistled "tyoooooo", a weak, hoarse "geep, were".

Habitat. Inhabits tropical lowland evergreen forest edge, secondary forest, clearings, mature mangroves, river-edge forest, typically in dense, low vegetation; thickets, dense canebrakes, vines, shrubby second growth, pastures, often near water or in marshy areas; mainly coastal and on major rivers in Guianas. Sea-level to 900+ m, occasionally to 1600 m in Colombia, to 2000 m in Venezuela.

Food and Feeding. Insects, including caterpillars, wasps, beetles, bugs, flies, also spiders. Forages in understory to mid-storey.

Breeding. Eggs Jun-Sept in Surinam; in French Guiana, fledgling recently out of nest in early Mar. Nest an open, deep twig cup in thick shrubs. Eggs 2, white; 24 x 19.5 mm, weight 4.6 g.

Movements. Not known. Considered resident.

Status and Conservation. Not globally threatened. Rather limited information available about relative abundance: species is uncommon to fairly common throughout much of range; local in Colombia.

Bibliography. Dubs (1992), French (1991), Haffer (1975), Haverschmidt & Mees (1994), Herklots (1961), Hilty & Brown (1986), Hostos & Chincilla (1994), Meyer de Schauensee & Phelps (1978), O'Neill (1974), Olog (1968), Phelps & Phelps (1958), Pinto (1938), Ridgely & Gwynne (1989), Schönwetter (1967), Sick (1985, 1993), Snyder (1966), Stotz *et al.* (1996), Terborgh *et al.* (1984), Tostain *et al.* (1992), Wetmore (1968), Zimmer (1930).

Subfamily CROTOPHAGINAE

Genus *CROTOPHAGA* Linnaeus, 1758

123. Greater Ani

Crotophaga major

French: Ani des palétuviers

German: Riesenani

Spanish: Garrapatero Mayor

Taxonomy. *Crotophaga major* J. F. Gmelin, 1788, Cayenne. Monotypic.**Distribution.** E Panama through tropical South America mainly E of Andes to N Argentina; Trinidad.**Descriptive notes.** 46 cm; male 162 g, female 145 g. Adult sleek glossy blue-black with bronzy green feather edges; iris white; bill compressed, with high-arched ridge at base of upper mandible, black; feet black. Juvenile iris brown. Voice. Noisy, guttural to bubbling, melodious "kro-koro", a growl, croaks, grates, hisses and whirs.**Habitat.** Flooded tropical evergreen forest, river-edge forest, gallery forest, in dense vegetation, thickets and trees along rivers, lakes, swamps and mangroves, wet forest edges, lake margins, grassy edges, thick viny and shrubby growth, marshes, often in vegetation overhang-

ing water: moves into clearings, does not move far into forest; occurs in villages in lowlands of Guianas. Occurs from lowlands to 800 m, mainly below 500 m, casually much higher in savannas (perhaps on migration), to 2600 m in E Andes of Colombia, and to 2550 m in Cochabamba, Bolivia.

Food and Feeding. Mainly insects, especially Orthoptera (grasshoppers, roaches), also caterpillars (Brassolidae), beetles, other arthropods, spiders, small lizards; fruit, berries, euphorbia seeds. Gregarious, feeds in flocks on ground and also in canopy; occasionally follows army ants, also follows groups of squirrel monkeys which flush insects; a gleaner insectivore.**Breeding.** Breeds May-Dec in Guyana, Apr-Sept in Surinam, Apr (nestlings) in French Guiana. Group-living, cooperative breeder, nests in loose colonies; groups defend territories against other groups. Nest a bulky mass of sticks and green leaves, on branches over water. Eggs 2-3 in Panama, 4-5 in Argentina (clutches of up to 6 may include eggs of more than one female), greenish blue covered by white chalky surface film; 45 x 38 mm.**Movements.** Resident; some local movements.**Status and Conservation.** Not globally threatened. Fairly common throughout its range. May possibly have occurred earlier in Mexico (S Tamaulipas), from where two 1960 specimens reported, but no evidence of its presence there either before or since. Said to be distasteful to cats and to human beings, this bird's body has a disagreeable odour.**Bibliography.** Belton (1984), Canevari *et al.* (1991), Chebez (1993), Contreras *et al.* (1990), Davis (1941a), Fjeldså & Krabbe (1990), Gyldestolpe (1945), Haverschmidt & Mees (1994), Herklots (1961), Hilty & Brown (1986), Howell & Webb (1990, 1995a), Meyer de Schauensee & Phelps (1978), Nellar (1993), Olson (1978), de la Peña (1988), Phelps & Phelps (1958), Ridgely & Gwynne (1989), do Rosário (1996), Schubart *et al.* (1965), Short (1975), Sick (1985, 1993), Snyder (1966), Stotz *et al.* (1996), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Thomas (1978), Tostain *et al.* (1992), Waldrigues *et al.* (1983), Wetmore (1939, 1968), Willis (1983), Willis & Eisenmann (1979), Young (1925, 1929).

124. Smooth-billed Ani

Crotophaga ani

French: Ani à bec lisse

German: Glattschnabelani

Spanish: Garrapatero Aní

Other common names: Black Witch, Tick Bird

Taxonomy. *Crotophaga Ani* Linnaeus, 1758, Jamaica. Monotypic.**Distribution.** C & S Florida, Bahamas, Caribbean Islands, Trinidad, Tobago; locally in Mexico (mainland and islands of Quintana Roo), Costa Rica and Panama, and S on W coast to Ecuador, E of Andes from Venezuela and the Guianas through E South American lowlands to N Uruguay and Chaco to N Argentina.**Descriptive notes.** 35 cm; male 115 g, female 95 g. Adult glossy black; skin around eye black, iris brown to black; bill high-arched and laterally compressed into thin keel, swollen at base, curving down to forehead, black; feet black. Juvenile bill smaller. Voice. Whining whistle, "ouee", rising in pitch and often given in flight; querulous "que-lick"; also chatters, mews, growls and clucks.**Habitat.** Second-growth scrub, river-island scrub, humid areas, clearings in humid forests and cloud forests, scrub and scattered trees in pastures, woodland, thickets, mangroves, lake margins, grassy/edges, marshes, thick viny growth, *Cecropia* and dying trees. Sea-level to 1200 m, mainly in lowlands; to 2300 m in Colombian Andes (where heart, lungs, and body weight larger than in lowlands).**Food and Feeding.** Insects, mainly grasshoppers, also mantids, fireflies, beetles including weevil root-borers (insect pests of sugarcane and citrus orchards), bugs, caterpillars (Brassolidae), Hymenoptera, rarely ticks; also lizards, small snakes, frogs, nestling birds and eggs; "Madame Jeanette" hot peppers, fruit and seeds in dry season. Lives in small flocks, walks on ground and on branches, flies in pursuit of insects; follows cattle, plough or army ants and captures flushed insects, also catches animals fleeing from grass fires. Climbs through vegetation, using its high-ridged bill to

separate the wet, dense vegetation as it forages; often spreads wings and tail to sun after plumage thus becomes wet.

Breeding. Breeds May-Oct in Florida, all year in Puerto Rico and Surinam, during rains in Cuba and Central America (after herbs grown and grasshoppers abundant). Group-living, cooperative breeder, but adults socially monogamous, rarely polygynous; several females may lay in one nest, clutches separated by layers of green leaves, and leaves added through incubation; reused nests may have old eggs under newer leaves. Nest a large, bulky, shallow mass of interlaced sticks, in tree or thicket. Eggs 4-20 or more (product of several females), oval, greenish blue covered by a white chalky surface film; 35 x 26 mm; laid at 2-day intervals. Incubation 13-15 days, by both sexes, male feeds female while she incubates. Hatchling naked, skin black, contrasting white marks on roof of mouth and around tongue, sheathed pin-feathers grow in a few days; cared for by both sexes, fledging 10-11 days, but if disturbed by 7 days and before capable of flight.**Movements.** Resident or locally nomadic. Post-breeding dispersive movements out of breeding range. **Status and Conservation.** Not globally threatened. Generally common. First established and bred in Florida in 1938, spread N along Florida coasts in 1960's, and now a well established breeder in most counties on E coast and on W coast N to Tampa Bay; numbers increased in S Florida during 1970's. In Central America, species has expanded its range during 20th century: first recorded in Costa Rica, near Panama border, in 1931, and by 1975 had extended to Guanacaste in N; replaced *C. sulcirostris* along S half of Pacific slope; also expanded its range in Panama from 1940's to 1960's. In Caribbean, somewhat surprisingly, this species is absent on most of the Lesser Antilles and on Barbados. Ubiquitous inhabitant of rank growth throughout extensive South American range. In the hand, birds have a rather strong and unpleasant smell.**Bibliography.** Allen (1961), Balch (1979), Barbour (1943), Belton (1984), Bent (1940), Biaggi (1983), Bond (1985), Brudenell-Bruce (1975), Buden (1977), Canevari *et al.* (1991), Chebez (1993), Contreras *et al.* (1990), Davis (1940a, 1942), Dod (1981), Emlen (1977), Fjeldså & Krabbe (1990), García (1996), Harrison (1978), Haverschmidt & Mees (1994), Herklots (1961), Hilty & Brown (1986), Howell & Webb (1995a), Howell *et al.* (1992), Kaufman (1996), Keith (1997), Klimaitis & Moschione (1987), Köster (1971, 1976), Loflin (1982, 1983), Meyer de Schauensee & Phelps (1978), Miller (1963), Monroe (1968), Olivares & Munves (1973), de la Peña (1988), Peterson (1980), Price *et al.* (1995), Reichhoff (1974), Ridgely & Gwynne (1989), do Rosário (1996), Rosenberg *et al.* (1990), Rutgers & Norris (1972), Schubart *et al.* (1965), Short (1975), Sick (1985, 1993), Skutch (1966), Slud (1964), Smith, S.M. 125. Groove-billed Ani

Crotophaga sulcirostris

French: Ani à bec cannelé

German: Riefenschnabelani

Spanish: Garrapatero Asurcado

Taxonomy. *Crotophaga sulcirostris* Swainson, 1827, Temascaltepec, Mexico.

Monotypic.

Distribution. Gulf of Mexico from Texas and Mexico S through Central America and W South America to N Chile and NW Argentina, and N South America E to Guyana; Netherlands Antilles. Disperses N into continental North America.**Descriptive notes.** 32 cm; male 80 g, female 70 g. Adult glossy black, long loose tail; skin around eye black, iris brown to black; bill arched, laterally compressed, no hump at base, upper ridge continuous with crown, upper mandible with grooves, black; feet black. Juvenile dull black, plumage loose-webbed (unlike adult), bill without grooves. Voice. Series of "tijo" notes, the first upslurred, given in excitement or alarm; also a faster series, a querulous "whee-o", a long series of rapid whistled "kiw" notes downslurred at end, a long mournful call, and a cluck.**Habitat.** Second-growth scrub, thickets, drier scrubby areas, pastures, fields, marshes, cleared and disturbed areas in range of original vegetation, from tropical evergreen forest to tropical scrub. Sea-level to 2300 m.**Food and Feeding.** Insects, mainly grasshoppers, also cockroaches, grubs, cicadas, flies, wasps, ants, spiders; small vertebrates, including *Anolis* lizards, and seeds and berries. Feeds in groups, walking on dry ground, often with cattle and sheep, where it catches insects more rapidly than when hunting alone, especially when pursuing fleeing grasshoppers in flight; digs in cow dung for grubs, dung-beetles and other insects; rarely, takes ticks from backs of cattle. Occasionally follows army ants.**Breeding.** Breeds May-Jul in Oaxaca, Jun to early Sept in Caribbean lowlands; in Costa Rica in rainy season Jun-Nov, later in years when rains delayed; in Curaçao has bred 4 times in succession Dec 1980-Sept 1981. Group-living, cooperative breeder; several females may lay in one nest, each attended by her mate. Nest a large, open bulky platform of sticks, roots and thorns, lined with green leaves, in shrub and tree; green leaves added through laying and incubation. Eggs 3-4/female, up to 18/nest, greenish blue covered with white chalky surface film, easily scratched; 31 x 24 mm; laying interval 2-3 days. Incubation 13-14 days, by both sexes, in spells of 30-60 min at a time. Nestling black, naked, no hair-like down, but with much down on fledging; young brooded for first week, when disturbed leave nest and climb branches by day 6, if undisturbed remain to 10 days in nest; tended by parents for 3 weeks after fledging. Parents then add to old nest and repeat cycle.**Movements.** Resident, but nomadic. After breeding season, occasional birds appear 1000 km from nearest breeding areas. In Florida, appear in autumn and winter on Gulf coast, mainly in coastal scrub; autumn records in S Great Plains. Lives in flocks in non-breeding season, roosting in large groups of 30-40 birds.**Status and Conservation.** Not globally threatened. Common to abundant in much of range, replaced by *C. ani* in Pacific areas of Central America; formerly lived also on islands of S Baja California. Territories of social groups comprise 1-10 ha; birds inhabiting marshy areas have large breeding units and small territory sizes compared with those in pastures. Generally much less common than *C. ani* in areas of sympatry in South America.**Bibliography.** Araya & Millie (1986), Balch (1979), Bent (1940), Berger (1952, 1954), Binford (1989), Bolen (1974), Bowen *et al.* (1989, 1991), Canevari *et al.* (1991), Fjeldså & Krabbe (1990), Harrison (1978), Hernández *et al.* (1981), Hilty & Brown (1986), Howell & Webb (1995a), Johnson (1967), Kaufman (1996), Koford *et al.* (1986, 1990), Lowery & Dalquest (1951), Meyer de Schauensee & Phelps (1978), Miller (1932), Monroe (1968), de la Peña (1988), Peterson (1980), Phelps & Phelps (1958), Price *et al.* (1995), Rand (1953), Ridgely & Gwynne (1989), Rowley (1984), Schaldach (1963), Skutch (1959b, 1983), Slud (1964), Smith, S.M. Genus *GUIRA* Lesson, 1830

126. Guira Cuckoo

Guira guira

French: Guira cantara **German:** Guirakuckuck **Spanish:** Pirincho
Other common names: White Ani

Taxonomy. *Cuculus Guira* J. F. Gmelin, 1788, Brazil. Monotypic.
Distribution. E & S Brazil, W to Bolivia and Paraguay, and S to Uruguay and N & E Argentina.
Descriptive notes. 36 cm; male 140 g, female 143 g. Adult shaggy-looking above, back and wings white-streaked brown, short orange-rufous crest, lower back white, tail blackish with broad whitish lateral area at base and at tip, central rectrices all dark except at base; whitish below, striped brown on throat and breast; bare facial skin yellow, iris yellow to orange, bill orange to yellow, feet bluish grey. Juvenile with small white spot on tips of remiges, bill black and white, iris light grey. Voice. Noisy, plaintive whistles, "pio...pio...pio...pr...prrr", also guttural calls, a high gargled trill, and a "creep".
Habitat. Second-growth scrub, drier tree and scrub savanna and scrub woodlands, pampas, pastures, coastal dunes. Groups huddle together on cold days and perch together in a tree at night. Roosts in trees. Sea-level to 1200+ m.
Food and Feeding. Insects, grasshoppers, cicadas, flying termites, frogs; eggs and nestlings of small birds; takes mice and rats in captivity. Gregarious, feeds on ground in flocks of up to 20 (mean group size 6-8).

Breeding. In Brazil, some nest in dry months May-Aug but mainly in rains during Aug-Nov near Brasília, also Aug-Nov near Rio de Janeiro; Nov-Dec in Uruguay and Argentina. Group-living; flocks decrease in size in spring, when some groups split into pairs to breed. Sometimes lays in nests of other species, including anis, and may incubate with the anis. Nest a large open platform of sticks, high in thorny tree; often renovates old nest from previous season. Eggs grey to turquoise with whitish chalky splotches and streaks raised in relief, variable within a nest; 28 x 37 mm, 25 g; a few nests have only one breeding pair, but in most

groups several females lay in the nest, average 10 eggs in a group nest (number of eggs greater in groups with more birds). Incubation 10-15 days; nestling pale-skinned, white hair-like down above, bill pale with black culmen ridge and mandibular rami, mouth-lining pale with raised papillae, black bar on tip of tongue; young leave nest by day 5 or 6 when disturbed, but typically fledge about day 15; 26% of eggs and 55% of hatchlings survive to fledging.
Movements. Resident. A vagrant (or escaped captive?) was found emaciated in Curaçao, though species unknown on the nearest mainland in Venezuela and Colombia.
Status and Conservation. Not globally threatened. Generally common. Has extended its range during the last 100 years, entering fields occupying deforested areas; common in Mato Grosso, SC Brazil, and also in E Bolivia; disappears with afforestation, and absent from forested parts of Amazonia. Has been bred in captivity, although the young may require hand-feeding.
Bibliography. Abrahamovich & Cicchino (1985), Belton (1984), Canevari *et al.* (1991), Cavalcanti *et al.* (1991), Chebez (1993), Contreras *et al.* (1990), Davis (1940b, 1942), Fandiño (1986, 1989), Fjeldså & Krabbe (1990), Gallardo (1984), Jenny (1997), Klimaitis & Moschione (1987), Laubmann (1930), Lückner (1995a), Macedo (1992, 1994), Mason (1985), Naumburg (1930), Nellar (1993), Olrog (1984), Pagei (1992), de la Peña (1988, 1996), Pinto (1964), Quinn *et al.* (1994), Reichholf (1974), do Rosário (1996), Rutgers & Norris (1972), Salvador (1981), Schubart *et al.* (1965), Short (1975), Sick (1985, 1993), Snethlage (1928), Souza (1995), Stotz *et al.* (1996), Waldrigues *et al.* (1983), Wetmore (1926).

Subfamily NEOMORPHINAE

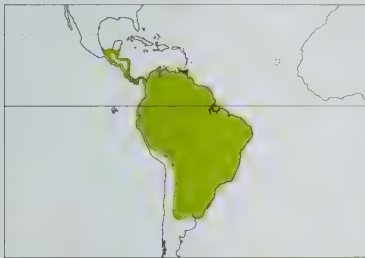

Genus *TAPERA* Thunberg, 1819

127. American Striped Cuckoo

Tapera naevia

French: Géocoucou tacheté **German:** Streifenkuckuck **Spanish:** Cuclillo Crespín
Other common names: Striped/Four-winged Cuckoo

Taxonomy. *Cuculus naevius* Linnaeus, 1766, Cayenne. Additional race *chochi* sometimes recognized for birds of S Brazil and N Argentina on basis of larger size and colour of upperparts, but these populations overlap considerably in size and plumage with birds in N Brazil and Venezuela. Two subspecies normally recognized.
Subspecies and Distribution. *T. n. excellens* (P. L. Sclater, 1858) - S Mexico to E Panama. *T. n. naevia* (Linnaeus, 1766) - Colombia E to the Guianas, and S to W Ecuador, N Peru and Brazil and on S to Bolivia, Paraguay and N Argentina; Margarita I (Venezuela) and Trinidad.

Descriptive notes. 26-29 cm; 52 g. Adult brown above, streaked buff and black, head with striped blackish and rufous crest, white supercilium and narrow black malar line, prominent black alula extended from wing; whitish below, sides of throat and chest with distinct black streaks, belly white; bare skin around eye yellow, iris brown to greenish, bill brown to orange-brown below, feet grey-brown. Juvenile more rufous, crown black with buff spots (not streaks), buff spots on back and upperwing-coverts, underparts buff with fine black bars, belly white with small dark spots (not streaks). Race *excellens* brighter, with

longer, deeper bill. **Voice.** Song 3-5 whistled notes, "pee-pee-pee-PEEdee". Call a mellow whistle, second note slightly higher, often repeated; differs regionally, whistle one syllable in NE Brazil, 3 syllables elsewhere in Brazil. Conspicuous when singing from post or wire.
Habitat. Second-growth scrub, low seasonally wet grassland, river-island scrub, open country with scattered trees, thickets and bushes, clearings in forested areas, brush at margins of tropical forests; sand-bathes along roadsides. Sea-level to 1500 m, occasionally to 2500 m in Venezuela.
Food and Feeding. Insects, especially grasshoppers, caterpillars: as with other parasitic cuckoos, young take whatever foster parents bring, including crickets, roaches, grasshoppers, caterpillars. Solitary, forages in vegetation and on ground; sways from side to side, fans the large alula perhaps to flush prey.
Breeding. Breeds Jun in S Mexico (Oaxaca), nearly all year in Surinam, nearly all year in French Guiana but sings most early in dry season. Brood-parasitic: hosts small birds with domed or covered nests, especially furnariid ovenbirds e.g. spinetails (*Synallaxis*, *Schoeniophylax*, *Certhiaxis*), wrens (*Thryothorus*), flycatchers (*Myiozetetes*), and sparrows (*Arremonops*). Enters nests at dawn, when adult hosts are foraging. Eggs white, pale blue or greenish blue; 22 x 17 mm; incubation 15-16 days (*Synallaxis* incubation 17-18 days). Eviction not described (closed nest may prevent eviction). Hatchling naked, pinkish, gape orange-yellow; within 24 hours uses sharp bill to kill host's chicks, which foster parent may remove; fledges in 18 days, remaining with foster parents for several more days.
Movements. Resident in most of range; seasonal in Argentina, where adults migrate from breeding area (Tucumán) earlier than the young.

Status and Conservation. Not globally threatened. A shy and solitary species, variably common to uncommon; call is one of typical sounds of areas of secondary growth in South America. Species has expanding range in the past 50 years, in response to deforestation in Central America and Brazil.
Bibliography. Bangs & Penard (1918), Belton (1984), Binford (1989), Canevari *et al.* (1991), Chebez (1993), Contreras *et al.* (1990), Dean (1971), Fjeldså & Krabbe (1990), Friedmann (1933), Haverschmidt (1955, 1961), Haverschmidt & Mees (1994), Hellmayr (1929), Herklots (1961), Hilty & Brown (1986), Howell & Webb (1995a), Kiff & Williams (1978), Klimaitis & Moschione (1987), Loetscher (1952), Marton & Farabaugh (1979), Meyer de Schauensee & Phelps (1978), Mitchell (1957), Monroe (1968), Morgensen (1927), Morton & Farabaugh (1979), Nellar (1993), de la Peña (1988, 1993, 1996), Pinto (1938), Ridgely & Gwynne (1989), do Rosário (1996), Salvador (1982), Schubart *et al.* (1965), Short (1975), Sick (1953a, 1981b, 1985, 1993), Slud (1964), Snyder (1966), Stiles & Skutch (1989), Stotz *et al.* (1996), Thomas (1979), Tostain *et al.* (1992), Wetmore (1926, 1968).

Genus *DROMOCOCCYX* Wied, 1832

128. Pheasant Cuckoo

Dromococcyx phasianellus

French: Géocoucou faisán **German:** Fasanenkuckuck **Spanish:** Cuclillo Faisán

Taxonomy. *Macropus phasianellus* Spix, 1824, Tonantins, north-west Brazil. Population of Mexico and Central America often recognized as race *ruficularis*, this being based on a bird in juvenile plumage; neither juveniles nor adults, however, differ between areas. Monotypic.
Distribution. S Mexico (Oaxaca) and Central America to Panama, Colombia, Venezuela, the Guianas, Ecuador, Brazil and Amazonian Peru then on to Bolivia, Paraguay and N Argentina.
Descriptive notes. 36 cm; 80 g. Adult small-headed, thin-necked, dark brown above with scaly feathers, short rufous crest, white eye-stripe, long graduated tail with white tip; whitish below,

breast whitish buff with dusky streaks; eye-ring yellow-green, iris brown to yellow, bill blackish above, paler below, feet greyish brown. Juvenile sooty-brown, finely spotted buff on blackish crown, wing-coverts with round buff apical spots, buff ends to flight-feathers and uppertail-coverts, breast rich buff and unmarked or with dusky spots, belly whitish. **Voice.** Melancholy whistles, "se-sée-werrrrr", final note quavering; also a 4-note series, "sah, seh, si-see", rising in pitch, and a series of rattling, clucking notes.
Habitat. Tropical lowland evergreen forest, flooded tropical evergreen forest, tropical decidu-

ous forest, thickets and undergrowth, low-altitude cloud forest, forest borders and secondary woodland, lake margins with grassy edges, thick viny growth, *Cecropia* and dying trees. Sea-level to 1600 m.
Food and Feeding. Insects, including large grasshoppers; lizards.
Breeding. Breeds Apr-Jun in Oaxaca. Brood-parasitic: hosts are birds laying in open or covered nests, include tyrannid flycatchers (*Rhynchocyclus brevirostris*, *Myiozetetes*, *Fluvicola pica*). Eggs dull white or pale buff, wreath of rufous spots at large end; 24 x 16 mm.
Movements. Unknown.

Status and Conservation. Not globally threatened. Widespread, but uncommon to rare and local; secretive and solitary behaviour make it difficult to assess numbers and relative abundance, but species is certainly not common. Disappeared from Barro Colorado I in Panama in 1971.
Bibliography. Belton (1984), Binford (1989), Canevari *et al.* (1991), Contreras (1993), Hayes (1995), Hellmayr (1929), Hilty & Brown (1986), Howell & Webb (1995a), Howell *et al.* (1992), Meyer de Schauensee & Phelps (1978), Monroe (1968), Naumburg (1930), de la Peña (1988), Ridgely & Gwynne (1989), Ridgway (1916), Rowley (1966), Saibene *et al.* (1996), Schönwetter (1967), Schubart *et al.* (1965), Sick (1953a, 1953b, 1985, 1993), Sieving (1990), Slud (1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Terborgh *et al.* (1984), Wetmore (1968), Willis & Eisenmann (1979), Wilson (1992).

129. Pavonine Cuckoo

Dromococcyx pavoninus

French: Géocoucou pavonin **German:** Pfauenkuckuck **Spanish:** Cuclillo Pavonino

Taxonomy. *Dromococcyx pavoninus* Pelzeln, 1870, Araguay, Engenho do Gama and Arimani, Brazil. Monotypic.
Distribution. Venezuela and Guyana through E Ecuador, E Peru and Bolivia to Brazil (S to Mato Grosso, São Paulo and Rio de Janeiro), Paraguay and N Argentina (Misiones).

Descriptive notes. 28 cm; 48 g. Adult small-headed, thin-necked, dark above, with scaly feathers edged white on outer webs (frosted appearance), crown, face and short crest rufous, eye-stripe buff, cheek black, wings brown, coverts edged whitish, uppertail-coverts black with white tips, graduated tail brown with white tips and broad subterminal black band; unspotted rufous throat and breast, white belly; iris brown, bill black above, paler below, feet grey. Juvenile greyer, head grey-brown, white eye-stripe, back blackish with some buff-edged feathers, throat and breast greyish. **Voice.** Call a whistled "püü, pee, püü-pe-pe", first note lowest,

last note a half-tone higher.
Habitat. Lowland tropical evergreen forest, montane evergreen forest, scrub thickets, tangled forests with dense secondary woodland, heavy brush, transitional forest, seasonally inundated forest; occurs in areas with abundant *Heliconia* and *Ficus*. Lowlands to 1600 m, occasionally to 1900 m or more in Venezuela.
Food and Feeding. Insects. Forages on ground and in forest understorey.
Breeding. Brood-parasitic: hosts include species with closed or bag-shaped nests (Tyrannidae, Formicariidae). Eggs white with purplish spots; 21 x 15 mm. Host's young disappear after cuckoo hatches.
Movements. Resident.
Status and Conservation. Not globally threatened. A solitary cuckoo, uncommon to rare, not well known, and sensitive to habitat disturbance. Its distribution is patchy and discontinuous, though the species may be overlooked in some areas owing to its secretive habits.
Bibliography. Canevari *et al.* (1991), Chebez (1993), Gai (1949), Hayes (1995), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Neunteufel (1951), Olrog (1968, 1984), de la Peña (1988), Remsen & Traylor (1989), Saibene *et al.* (1996), Schönwetter (1967), Schubart *et al.* (1965), Short (1975), Sick (1953a, 1953b, 1985, 1993), Snyder (1966), Stotz *et al.* (1996), Terborgh *et al.* (1984).

Genus *MOROCOCCYX* P. L. Sclater, 1862

130. Lesser Ground-cuckoo

Morococcyx erythropygus

French: Géocoucou de Lesson **German:** Drosselkuckuck **Spanish:** Cuclillo Bobo
Other common names: Rufous-rumped Cuckoo

Taxonomy. *Coccyzus erythropyga* Lesson, 1842, San Carlos, Central America. Two subspecies recognized.

Subspecies and Distribution.

M. e. mexicanus Ridgway, 1915 - Pacific slope of tropical W Mexico from S Sinaloa S to Isthmus of Tehuantepec.

M. e. erythropygus (Lesson, 1842) - S Mexico (hills of Oaxaca on E side of Plains of Tehuantepec E to Chiapas) to NW Costa Rica, and also arid interior valleys on Caribbean slope of Guatemala and Honduras.

Descriptive notes. 25 cm; 62 g. Adult greyish brown above, with bronzy reflections on wings and long tail, rufous below; bare eye-ring and lores yellow, bare skin behind eye blue with black border, iris brown, bill yellow with black culmen, long legs yellow-brown. Juvenile duller above, scaled with pale feather edges, paler below, smudged dusky, bare orbital skin grey, bill brown above, lighter below. Race *erythropygus* larger and paler. **Voice.** A mellow whistle, "teecee"; a clear trilled whistled series with notes lower and more widely spaced, series introduced by 2-3 clear ascending whistles; also a growling "ghaaaoww"; female clacks mandibles.

Habitat. Arid lowland scrub, tropical deciduous forest edge in semi-arid scrub and woodland, thorny thickets on arid slopes. Sea-level to 1500 m, locally to 1800 m in Guatemala.

Food and Feeding. Insects, mainly grasshoppers. Forages in understorey, also on bare ground, at edges of cultivation; walks or hops among leaves on ground with chicken-like head and leg movements, picks food from ground or leaps to foliage; furtive, skulking, inquisitive, not shy.

Breeding. Breeds May in S Mexico (Oaxaca), Jul in Guatemala. Nest a shallow bowl of sticks and leaf petioles and rachises, lined with dead leaves, on ground. Eggs 2, chalky white or smooth white; 27 x 21 mm; incubation by both sexes, in spells of 2-4 hours at a time.

Movements. Resident.

Status and Conservation. Not globally threatened. Few details available, but species is reckoned to be generally fairly common, and habitat not thought to be under serious threat at present; species is locally common in Guanacaste, N Costa Rica.

Bibliography. Anon. (1983), Binford (1989), Davis (1972), Dearborn (1907), Edwards (1989), Howell & Webb (1995a), Land (1970), Monroe (1968), Ridgway (1916), Rowley (1984), Schaldach (1963), Skutch (1966, 1983), Slud (1964), Stiles & Skutch (1989), Stotz *et al.* (1996).

Genus *GEOCOCCYX* Wagler, 1831

131. Greater Roadrunner

Geococcyx californianus

French: Grand Géocoucou

German: Wegekuckuck

Spanish: Correcaminos Grande

Taxonomy. *Saurothera californiana* Lesson, 1829, California.

Population from Texas (USA) S to Nuevo León and Veracruz (Mexico) averages smaller and has been described as race *dromicus*; but birds from this region overlap in size with those in other parts of range. Monotypic.

Distribution. SW USA and Mexico, from California, Utah and Colorado E inland to Missouri and Louisiana, through coastal Texas and Baja California, S to Michoacán, Puebla and Veracruz.

Descriptive notes. 56 cm; male 320 g, female 290 g. Large and slender, with long tail and long legs; streaked brown above with bronze gloss, shaggy blue-black crest, tail with broad white tips on outer 3 rectrices; whitish below with brown streaks; eye-ring blue, bare skin behind eye usually white (male) and orange, iris brown with yellow ring, bill blackish, feet grey. Female averages smaller, postorbital skin usually blue and orange. Juvenile duller, feather tips more pointed, with white U-shaped patches on tips of primary coverts; white tips of rectrices wedge-shaped, rather than oblong; postorbital skin as in adult female, inner iris develops grey ring around pupil, outer iris brown. **Voice.** Mournful dove-like "coo" notes, slow and descending in pitch; also a bill-rattle.

Habitat. Arid scrub, lowland or montane; widely dispersed in dry open country with scattered brush, mesquite, palo verde, creosote, cholla cactus, prickly pear cactus, upper oak and piñon pine scrub, in yucca and shortgrass plains of N Texas panhandle; also in tall pines and magnolias in E Texas; clearings in farms and dry scrubby woods. Roosts and feeds in shelter of trees and rocks. Mostly in arid and semi-arid regions having at least 140 clear sunny days from sunrise to sunset; N limit to range determined by prolonged deep snow cover. Occurs from lowlands up to 2500 m.

Food and Feeding. Opportunistic carnivore, taking: insects (grasshoppers, crickets, cicadas, caterpillars, beetles), scorpions, centipedes, spiders (including tarantulas), toads, lizards, small snakes (including rattlesnakes), small birds and eggs, mice, young ground squirrels, young rabbits, young bats fallen from cave ceilings, roadside carrion; also, up to 10% of diet made up of fruits and seeds, e.g. prickly pear (*Opuntia*) cactus, sumac (*Rhus integrifolia*). Terrestrial and cursorial, foraging solitary or in pairs; can fly, but usually runs on bare ground under cover; runs after prey on ground, leaps at flying insects, tosses and batters lizards and snakes against a stone, attacks scorpions by the tail; members of pair sometimes co-operate in attacking a snake.

Breeding. In S California, breeds from late Feb in low elevations of Lower Sonoran Life Zone, a month later in upland deserts of Upper Sonoran Life Zone; in S Arizona from mid-Apr to mid-Jun and late Jul to mid-Sept, with pause in hot dry summer and increased nesting after summer rains (varies with annual rains); in Texas breeds Mar-Oct, in Oklahoma Apr-Jul/Aug. Breeding male feeds mice, small birds, snakes and lizards to his mate. Nest is an open bulky platform of sticks, lined with leaves, snakeskins, dung and mesquite seed-pod debris; often placed in shade, 1-3 m up in bush, low tree, thicket or cactus clump. Eggs 2-6 (clutches larger after summer rains), white, 39 x 30 mm; laying interval often 2 days, but variable; incubation 17-18 days, by male at night and by both sexes in daytime, female having one

bout in morning and one in afternoon; hatching asynchronous, age differences of nestlings up to 7 days. Hatchling 14 g, nearly naked, skin black (throat whitish) with short (1-7 mm) whitish hair-like feather sheaths, gape flange pink, mouth red with white upper palate, raised area of white papillae on each side of palate and at base of throat, feet black; cared for by both parents; half adult weight at 14 days; when disturbed, nestlings give loud vocal "churr", also bill-rattle, and will also excrete a blackish foul-smelling liquid; fledging 17-19 days; young fed by adults for further 2 weeks; follow parents to feeding areas and catch their own food within 2-3 weeks. Pair can nest again a month after first nesting, male taking over care of fledglings while female lays second clutch; single-brooded, double-brooded or even triple-brooded, depending on weather. In Texas 73% of nests were robbed by predator, 22% of eggs survived to fledge, and a pair that nested twice could produce on average 3.5 chicks in a season; in another study, in New Mexico and Oklahoma, 66% of eggs laid hatched, 87% of nestlings fledged, and overall nest success was 72%.

Movements. Resident. Pair remains on territory all year and in successive years; one remained 5 years in the same site. A pair may sometimes move together to a new territory and reneest c. 1-6 km from an earlier nest, while other birds move independently of their mate, in both cases after failure of earlier nest. No evidence of seasonal movements. Juveniles thought to disperse from their natal territories.

Status and Conservation. Not globally threatened. Common to fairly common; population numbers over most of range have shown no significant change in period 1966-1993. Most numerous in SE California, S Arizona (Chihuahuan Desert) and Texas W of Pecos R and S of Edwards Plateau. Density on rocky slopes in S California 0.65 birds/km², lower in other desert habitats; in coastal S Texas 3 birds/km²; territories average 0.5 km². Adult annual survival at least 60% (few ringing recoveries). During 20th century, range has expanded N and E in California, E Kansas and Oklahoma, and across Ozarks into basin of Mississippi R; land clearance, overgrazing, and a later reinvasion of scrub may be involved in the eastern range expansions. On a more local scale, range is decreasing in urban areas (see page 545), where habitat is developed for agricultural and residential development, and the species has been extirpated in Central Valley and S counties of California. Has bred in captivity.

132. Lesser Roadrunner

Geococcyx velox

French: Géocoucou véloce

German: Rennkuckuck

Spanish: Correcaminos Chico

Taxonomy. *Cuculus velox* Wagner, 1836, Mexico.

Has on occasion been subdivided into as many as five races. Monotypic.

Distribution. W Mexico from S Sonora to Chiapas, on central plateau from Nayarit and Jalisco S to México, Morelos, Puebla, Veracruz and Oaxaca; also Yucatán, and Central America from Guatemala, El Salvador and Honduras to C Nicaragua.

Descriptive notes. 48 cm; 178 g. Adult crested and long-tailed, streaked brown above, buff below, sides of neck and breast streaked, undertail-coverts tan, darker than belly; bare skin behind eye blue, extending back to red patch, iris yellow to brown, tarsi grey-green. Juvenile with buff feather tips above, dark spots (not streaks) on breast, bare skin around eye blue (as adult). **Voice.** Call a soft "coo", about 1/sec, repeated on descending scale.

Habitat. Arid lowland scrub, arid montane scrub; dry open country with scattered brush, thorn scrub, grassy and lightly wooded hillsides, farmland. Sea-level to 2800 m, occasionally to 3000 m.

Food and Feeding. Insects, mainly grasshoppers and caterpillars. Foraging behaviour much as for *G. californianus*.

Breeding. Breeds in Mexico in Apr (Veracruz) and May-Jul (Oaxaca); Apr-May in Guatemala, Aug in El Salvador. Nest a bulky stick platform, built above ground in bushy tree, thorn bush or centre of an *Opuntia* cactus thicket. Eggs 2-3 (2-4), white; 35 x 26 mm.

Movements. Resident.

Status and Conservation. Not globally threatened. Few details available, but species is reckoned to be generally fairly common throughout its range; habitat not thought to be under serious threat at present.

Bibliography. Anon. (1983), Binford (1989), Blake & Hanson (1942), Dearborn (1907), Howell & Webb (1995a), Land (1970), Miller (1932), Monroe (1968), Moore (1934), Owen (1861), Rowley (1984), Schaldach (1963), Schönwetter (1967), Selander & Giller (1959), Short (1974), Stotz *et al.* (1996).

Genus *NEOMORPHUS* Gloger, 1827

133. Rufous-vented Ground-cuckoo

Neomorphus geoffroyi

French: Géocoucou de Geoffroy

German: Geoffroykuckuck

Spanish: Cuco-hormiguero Ventrirrifo

Other common names: Scaled Ground-cuckoo (*squamiger*)

Taxonomy. *Coccyzus geoffroyi* Temminck, 1820, Pará, Brazil. Form *squamiger* may be better treated as a full species. Seven subspecies currently recognized.
Subspecies and Distribution.
N. g. salvini P. L. Sclater, 1866 - Nicaragua, Costa Rica, Panama and Pacific coast of Colombia.
N. g. aequatorialis Chapman, 1923 - SE Colombia, Ecuador and N Peru.
N. g. australis Carriker, 1935 - Peru and NW Bolivia.
N. g. geoffroyi (Temminck, 1820) - Brazil S of Amazon (Para).
N. g. squamiger Todd, 1925 - Brazil S of Amazon (lower R Tapajóz area).
N. g. maximiliani Pinto, 1962 - E Brazil (Bahia).
N. g. dulcis Sneath, 1927 - SE Brazil (Espírito Santo to Rio de Janeiro).

Descriptive notes. 50 cm; c. 340-349 g. Race *salvini* bronzy-brown above, glossed green on wings, crest black, forehead buff to cinnamon-brown, breast with dusky semicircular bands, narrow black band on chest, underparts buff with rufous vent; bare facial skin blue, iris brown, bill large, yellow-green, feet dark grey. Juvenile duller, darker, with loose fluffy plumage, blackish with rufous-grey on belly, little gloss on wings and tail, bill dark. Race *geoffroyi* darker olive-green above, with white barring on crown; *squamiger* with black band on chest indistinct; *australis* with crest unmarked; *dulcis* dark blue above; *maximiliani* dark bronze-green above with purplish tail; *aequatorialis* bronzy-green above, forehead warm brown, breast feathers with broad pale tips. Voice. Loud bill-clapping; soft dove-like moaning "ooooo-oóp", low "woof" at army-ant raids, and loud "kchak!" in feeding competition.

Habitat. Tropical lowland evergreen forests, high-ground forest, also transitional forest with seasonal inundations, in *Ficus* and *Heliconia*, canebrakes and thickets. Lowlands and foothills to 1200 m, to 1650 m in Bolivia.

Food and Feeding. Large insects, scorpions, centipedes, spiders, small frogs, lizards, occasionally seeds and fruit. Terrestrial, wary and agile; runs and can flutter to elevated perch but not seen to sustain flight. Looks into heaps of branches, armadillo holes, empty terrestrial-termite mounds; often forages at army-ant swarms, runs and bill-snaps at edges of ant raids, or tosses leaf litter, also follows peccaries; leaps over logs, dashes about on ground, flicks aside leaves and pecks at insects in litter, captures flushed arthropods in short runs along ground.

Breeding. Breeds in northern summer or wet season as far S as N Colombia, where oviduct egg in Apr; in southern summer in SE Brazil. Nest a broad shallow bowl of sticks, lined with green leaves added daily, built in dense swampy vegetation; fresh green leaves added during incubation. Lays 1 egg, yellowish white; 40 x 32 mm. Adults attend their fledged young away from nest.

Movements. Resident.

Status and Conservation. Not globally threatened. A rare and local, solitary species which requires large blocks of natural forest. Population density 0.25 pairs/100 ha in floodplain forest in Amazonian Peru. Like other ground-cuckoos, it is apparently unable to cross the large rivers, which are barriers to its dispersal; this is one of the first birds known to have disappeared from Barro Colorado I, Panama, after flooding separated it from the mainland forest. Race *squamiger*, sometimes reckoned to be a separate species, is considered near-threatened because of its restricted range. Populations of ground-cuckoos in S Brazil would also appear to be under threat, and are disappearing as a result of deforestation.

Bibliography. Griscom & Greenway (1941), Gyldenstolpe (1945), Haffer (1975, 1977a), Hilty & Brown (1986), Howell (1957), King (1978/79), Pinto (1962, 1964), Ridgely & Gwynne (1989), Robbins *et al.* (1985), Roth (1981), Schubart *et al.* (1965), Scott & Brooke (1985), Sick (1949, 1962, 1985, 1993), Sick & Teixeira (1979), Slud (1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Wetmore (1968), Willis (1974, 1982), Willis & Eisenmann (1979).

134. Banded Ground-cuckoo

Neomorphus radiolus

French: Géocoucou barré **German:** Bindengrunkuckuck **Spanish:** Cuco-hormiguero Escamoso

Taxonomy. *Neomorphus radiolus* P. L. Sclater and Salvin, 1878, Intac, Ecuador. Monotypic.

Distribution. Foothills of SW Colombia and NW Ecuador.

Descriptive notes. 50 cm. Adult large, black above and below, the feathers edged buffy white giving a striking scaly effect; crest black, wing-coverts chestnut, inner wing purplish red, outer primaries black, long tail black with purplish gloss; bare skin around eye blue, iris dark brown, bill heavy, dusky above, yellowish below, feet bluish grey. No information available on juvenile plumage. Voice. Unknown.

Habitat. Tropical lowland evergreen forest, in foothills and lower slopes on Pacific slope of W Andes. From 450 to 1525 m, mainly 500-1200 m.

Food and Feeding. Not described in detail.

Terrestrial; follows peccaries.

Breeding. No information.

Movements. Resident.

Status and Conservation. **ENDANGERED.** A rare and local, poorly known cuckoo, observed at a total of only 6 localities in SW Colombia (in Valle, Cauca, Nariño) and 6 in NW Ecuador (in

Esmeraldas, Imbabura, Pichincha). It is globally threatened owing to its fragmented and highly local populations, and also due to widespread forest destruction; only three records in Colombia since 1956, and a mere one in Ecuador since 1936 (in 1992). In 1990's, local hunters in Nariño reported it as fairly common but exceedingly shy. Sensitive to habitat disturbance. Biology virtually unknown.

Bibliography. Bond & Meyer de Schauensee (1940), Butler (1979), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Dunning (1982), Evans, R.J. (1988), Haffer (1977a), Hartert (1898b), Hilty & Brown (1986), Lönnberg & Rendahl (1922), Meyer de Schauensee (1982), Negret (1991), Ortiz & Carrión (1991), Salaman & Gandy (1993, 1994), Sclater & Salvin (1878), von Sneider (1954), Stotz *et al.* (1996), Wege & Long (1995).

135. Rufous-winged Ground-cuckoo

Neomorphus rufipennis

French: Géocoucou à ailes rousses

Spanish: Cuco-hormiguero Alirrufo

German: Rotschwingen-Grundkuckuck

Taxonomy. *Cultrides rufipennis* G. R. Gray, 1849, lower Orinoco River, Venezuela. Monotypic.

Distribution. S Venezuela, Guyana and N Brazil (Roraima, near upper R Branco).

Descriptive notes. 50 cm. Adult dark bronzy-green above, crest purplish-glossed black, head, neck and chest purplish blue-black, throat ashy-white to grey (black on some), dull grey-brown below, undertail-coverts grey, inner flight-feathers purplish red, primaries dark brown; bare skin on face red, iris red in male to brown in female, bill black with greenish tip, feet greenish grey to grey-blue. No information available on juvenile plumage. Voice. Single call a hoot, "whoó", repeated in no regular pattern, dove-like; also loud snapping of bill.

Habitat. Tropical lowland evergreen forest, including forest in highlands, in interior foot-

hill zone. Lowlands to 1100 m, possibly higher.

Food and Feeding. Diet not recorded, probably similar to that of congeners. Solitary, wary and restless, runs fast on ground, perches in middle branches of trees; often seen near bands of peccaries.

Breeding. Nest unknown. Eggs yellowish white; 40 x 31 mm.

Movements. Resident.

Status and Conservation. Not globally threatened. Like its congeners, this is a rare and poorly known species requiring further field research. Known to be sensitive to habitat disturbance.

Bibliography. Haffer (1977a), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Pinto (1964), Ruschi (1979), Schönwetter (1967), Sick (1985, 1993), Snyder (1966), Stotz *et al.* (1996).

136. Red-billed Ground-cuckoo

Neomorphus pucheranii

French: Géocoucou de Pucheran

Spanish: Cuco-hormiguero Piquirrojo

German: Rotschnabel-Grundkuckuck

Taxonomy. *Cultrides Pucheranii* Deville, 1851, Rio Yaguas, Peru.

Two subspecies recognized.

Subspecies and Distribution.

N. p. pucheranii (Deville, 1851) - Amazonian Peru and W Brazil N of R Amazon.

N. p. lepidophanes Todd, 1925 - Amazonian Peru and W Brazil S of R Amazon.

Descriptive notes. 50 cm. Adult green-glossed brown above, crest black with purple gloss, wings rufous, outer primaries black, glossed violet, tail green-glossed purplish black; buffy below, throat grey, breast scaled black, black breast band, belly buffy to light grey; bare skin on face red, blue behind eye, bill red with yellow tip, feet dark grey. Juvenile plumage loose-webbed, unglossed brown above, crest blackish, wing dark brown, throat and breast blackish, belly brown, bill and feet black. Race *lepidophanes* with lower breast and belly clay colour. Voice. Calls include a roaring hum like a curassow (*Crax*); also a bill-snapping.

Habitat. Tropical lowland evergreen forest of upper Amazonia. Lowlands to 700 m.

Food and Feeding. Insects. Terrestrial; walks and runs on ground, leaps, regularly forages at army-ant swarms.

Breeding. Insufficient data. Nestling in Peru in Feb; buffy hair-like natal down attached to tip of growing contour feathers on head, bill black.

Movements. Resident.

Status and Conservation. Not globally threatened. A rare species, about which little is known. Not often seen. A reported sighting in S Colombia (Amazonas) indicates that its range may possibly be slightly larger than currently known. Sensitive to habitat disturbance.

Bibliography. Cuadros (1991), Dunning (1982), Haffer (1977a), Hilty & Brown (1986), Meyer de Schauensee (1982), Parker *et al.* (1982), Peres & Whittaker (1991), Pinto (1964), Ruschi (1979), Sick (1953b, 1985, 1993), Siegel *et al.* (1989), Stotz *et al.* (1996), Willis (1982), Willis & Oniki (1978).
